JANUARY 3, 1896.—VOL LXXXI.

THE ENGINEER.

AMERICAN SELF-PROPELLED CARRIAGES.

THE final competitive run of motor carriages in Chicago, which was made on November 28th, seems at first to have been very disappointing, although, as a matter of fact, it was probably as successful an exhibition as could have been made, considering the comparative novelty of practical motor carriages, and considering also the very unfavourable conditions of the weather and the roads. As mentioned in the article in THE ENGINEER of November 22nd, the date of the trial was changed from November 2nd to November 28th, on account of the number of applications for a longer time in which to put the finishing touches on the machines. The number of entries originally made was about ninety, but the practical machines entered and those actually built for the competition numbered probably less than a score. About a dozen were finally entered for the trial, but of these only six started, and of these six carriages two made the entire trip, one nearly completed it, and three withdrew after making short runs. It must be remembered, however, that some of the carriages which failed to start for the competitive run for various reasons are practical and commendable machines, which have been used more or less extensively by their owners and builders. Of these something will be said further on.

TABLE A.

Competition of Motor Carriages at Chicago, U.S.A., November 28th, 1895.

	Duryea.	Mueller.	Roger.	Morris and Salom.	Sturges.	De La Vergne.

Distance run, miles	54.36	54.36	40	12	13	4
Average speed, miles per hour	7	5¾	5	4	4¼	2¾

The route was changed from that originally planned, being from Jackson Park, in Chicago, to Evanston and back by a different route, the distance being 54·36 miles, with three relay stations at distances of 14, 26, and 44 miles from the starting point. The first part of the route was along a well built boulevard, followed by asphalt, brick, stone block, and wooden block pavements for short distances, and again by another boulevard; thence to Evanston the road was sandy and gravelly, in some parts very rough, and in others very soft in wet weather. Through Evanston there were about 3½ miles of good smooth wooden block pavement, followed by good macadam roads nearly all the way back to the starting point, except for short stretches of asphalt, stone block, and one short piece of unimproved clay road, which is almost impassable in wet weather. The entire route was practically level, the only grades of any steepness being the short approaches to bridges over the railways and the Chicago River. The roads are wide, the turns not sharp, and of the whole distance only about five miles were bad even in wet weather. Tramway tracks are laid on some of the streets traversed, and on about twenty streets which the carriages had to cross.

A heavy storm of wet sticky snow prevailed a day or two before the date of the trial, sufficient for sleighing in the parks, and on November 28th the roads were covered with snow and slush, fully 6in. deep, being thus in very bad condition for carriages with or without horses.

The carriages taking part in the competition, and a summary of their performances, are shown in Table A.

(1) *Duryea motor carriage.*—This was the four-wheel carriage with gasoline motor illustrated and described in THE ENGINEER of November 22nd. It weighs 1000 lb. complete, and has been used somewhat extensively. It dislocated its steering gear soon after starting by running over a snow bank, and fifty-five minutes were consumed in making repairs, after which it ran on to Evanston, about twenty miles, without a stop. On the return trip it was delayed four minutes by running into an overturned sleigh, and then went two miles on a wrong road, during which time a stop of fifty-five minutes was made to repair the sparking apparatus. Supplies were taken in at two relay stations, and the engine consumed three and a-half gallons of gasoline and nineteen gallons of water. Two persons were carried. This carriage was built by the Duryea Motor Wagon Company. It is said to have developed 4-horse power and a speed of twenty-seven miles per hour on the testing machine already described, and it has attained a speed of sixteen miles per hour on good roads. It carries a supply of gasoline sufficient for about 100 miles run on good roads. In the carriage used the power is transmitted from the gears to the rear axle by a chain, but in the new carriage belts and gears will be used. The price quoted is from £200 to £400.

(2) *Mueller motor carriage*—Fig. 1.—This is a four-wheel carriage, driven by a Benz gasoline motor. The trip was uneventful in the way of accidents or delays, no failure occurring, and the stops being mostly for the purpose of examining the machinery to see that all was right, or to take on supplies. Three gallons of gasoline were taken at each of the relay stations. The carriage had three passengers for the greater part of the distance, and then two passengers. This carriage was built by the H. Mueller Manufacturing Company.

(3) *Roger motor carriage.*—This was a four-wheel park phæton—closely resembling the carriage shown in Fig. 5—fitted with a Benz gasoline motor and imported from Paris. It worked satisfactorily, but was unable to do its best, owing to its steering gear having been damaged by a collision with a cab driven by a man who did not regard the motor carriage with favour. This damage caused it later on to run into a sleigh, damaging one of the wheels. Eventually the motor gave out, and the carriage came to a standstill, although it was then ahead of the Mueller carriage, and was well on its way on the return trip. Three delivery wagons for city work, fitted with Roger motors, have been put in trial service in New York and Philadelphia. [These are Roger parcel vans with Benz motors.—ED. E.] The wagon weighs 2300 lb., is fitted with a motor weighing 625 lb., and can carry 1300 lb. of goods or parcels and a supply of rectified petroleum sufficient for seventy-five hours' run. The wheels are of wood, with rubber tires, but wire wheels were used in the park carriage taking part in the competition. This latter carriage started to run from New York to Chicago before the race—nearly 1000 miles by road—but after travelling about 140 miles had to give up on account of the terrible condition of the roads, owing to snow and mud. It was then sent on by rail. This carriage was entered by R. H. Macy and Co., and carried two persons.

(4) *Sturges motor carriage.*—This was a three-seated sulky, for six persons, and weighing 2750 lb. in running order. For this run the rear seat was removed to make room for more batteries. It was built at the time of the Chicago Exhibition of 1893, by Mr. Harold Sturges, and has been in use more or less since that time. It is shown in Fig. 3. This carriage is mounted on four wheels, the front wheels being 3½ft., and the rear wheels 4ft. diameter. In the body were thirty-six storage battery cells, with a capacity of 250 ampère hours, the power stored being equivalent to 23 electrical horse-power. The motor was of 3-horse power, and the power was transmitted to the axle by single-reduction gearing. The cost of such a carriage is approximately £300. This carriage has a speed of three to ten miles per hour on good roads, and its battery should carry it seventy miles on a hard level road without re-changing, but owing to the condition of the roads and the lack of adhesion due to the 6in. of snow, causing the wheels to slip very badly, nearly double the usual power was exerted, and the carriage travelled at a speed of only four miles per hour, the batteries becoming exhausted after a run of thirteen miles. Nevertheless, no accident or breakage occurred, and Mr. Sturges states that during the past summer he ran the carriage at a speed of ten miles per hour on a smooth road, with only 3-horse power, giving a running capacity of seven hours, or about seventy miles.

(5) *Morris and Salom motor carriage.*—This was a storage battery carriage of a style which has been in experimental use for some time, but which is handicapped by the ridiculous name of "electrobat" bestowed upon it by its builders. As the severe conditions of the road had not been anticipated, and a sufficient supply of batteries had not, therefore, been sent to the relay stations, the carriage made an experimental run of only about twelve miles, and then went back to the testing room without a stop, using its own power. The batteries were changed twice during the run, the time consumed in changing the four 150 lb. boxes being five minutes in each case. This carriage, shown in Fig. 4, weighs about 1600 lb., but a somewhat smaller one, weighing 1200 lb., was used in the competition. The reduction of weight was effected by the use of steel tubes for the frame, and wire wheels. There are four sets of twelve chloride cells, supplied by the Electric Storage Battery Company, having a capacity of 50 ampère-hours per cell. When pushed into place automatic connection is made with the controller, which is operated by a hand wheel in front of the seat, and gives four rates of speed by various groupings of the batteries with the motors. The battery capacity is sufficient for

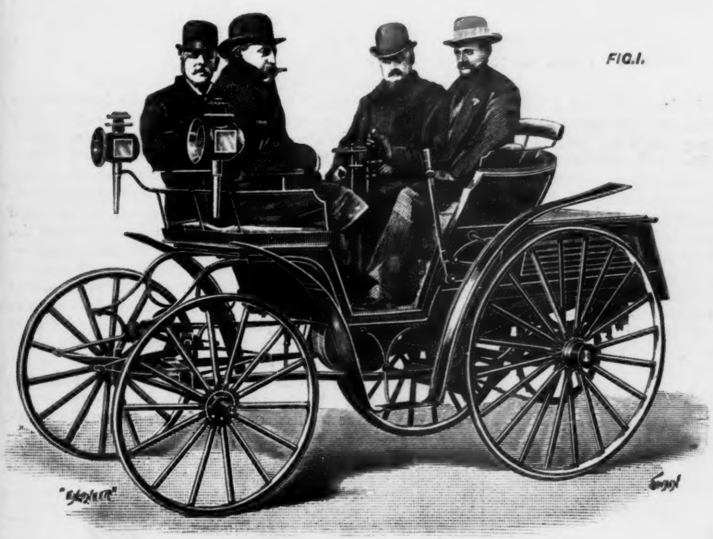

FIG.1.

MUELLER CARRIAGE WITH GASOLINE MOTOR

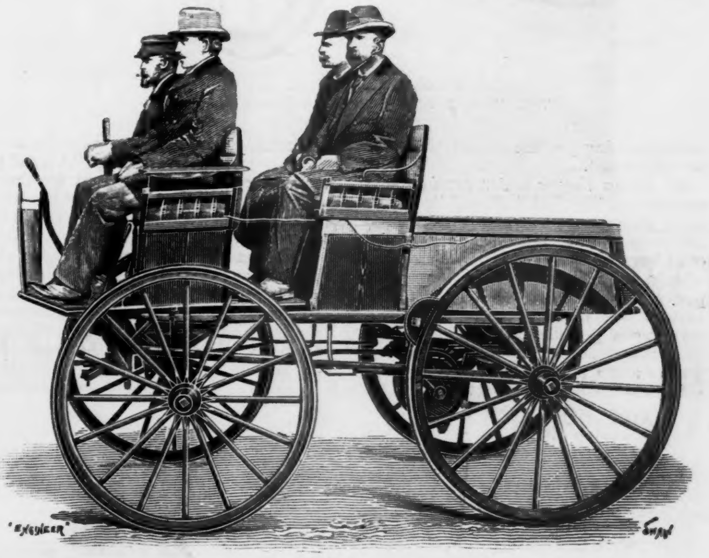

FIG.3

STURGE'S STORAGE BATTERY CARRIACE

twenty hours' run, and a speed of twenty miles per hour is said to be practicable on good roads. There are two Lundell electric motors of 1½ nominal horse-power, driving by pinions on the armature shafts the driving gears attached to the front axle. The steering is done by shifting the rear axle, which method is said to work very well. The carriage illustrated has wooden wheels, the front ones being 40in. and the rear wheels 28in. diameter. The carriage seats two persons, and was built by Morris and Salom. Storage battery carriages which have to change their batteries on the trip are seriously handicapped for ordinary use when compared with carriages having battery capacity for the entire trip, or carriages using gasoline motors, whose tanks can readily be replenished.

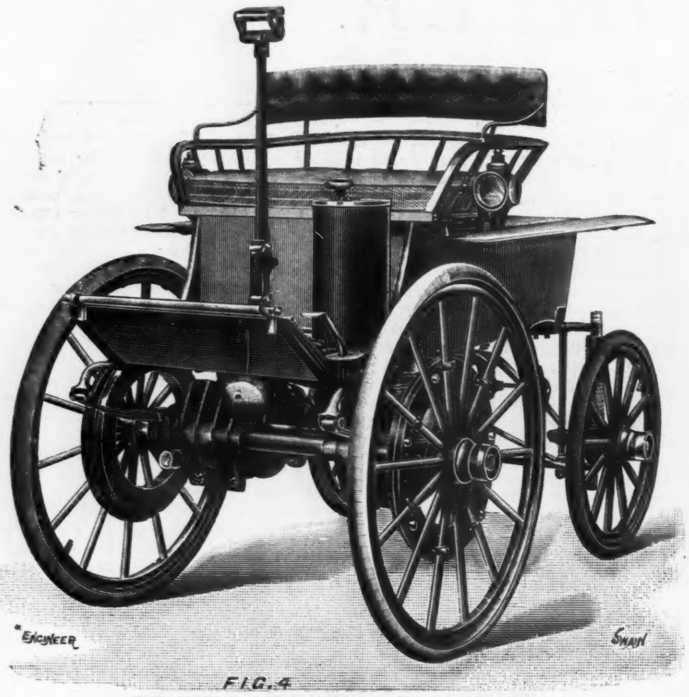

FIG. 4

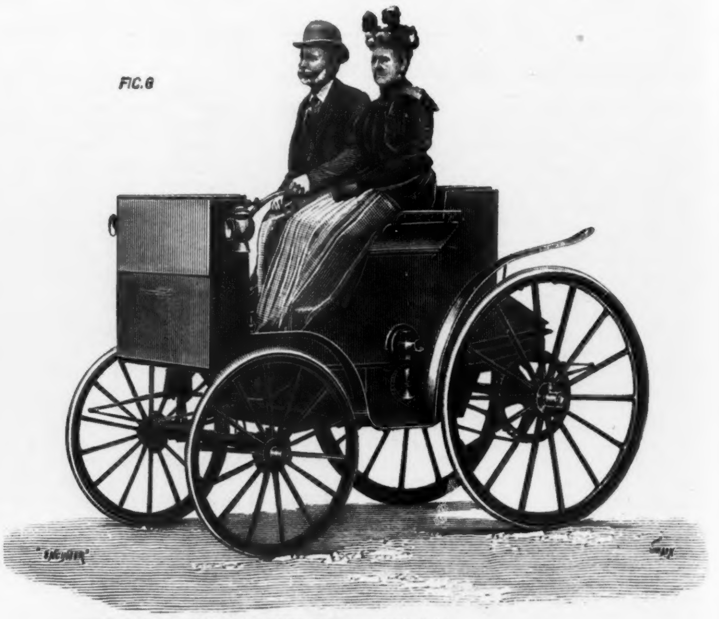
THE MORRIS AND SALMON STORAGE BATTERY

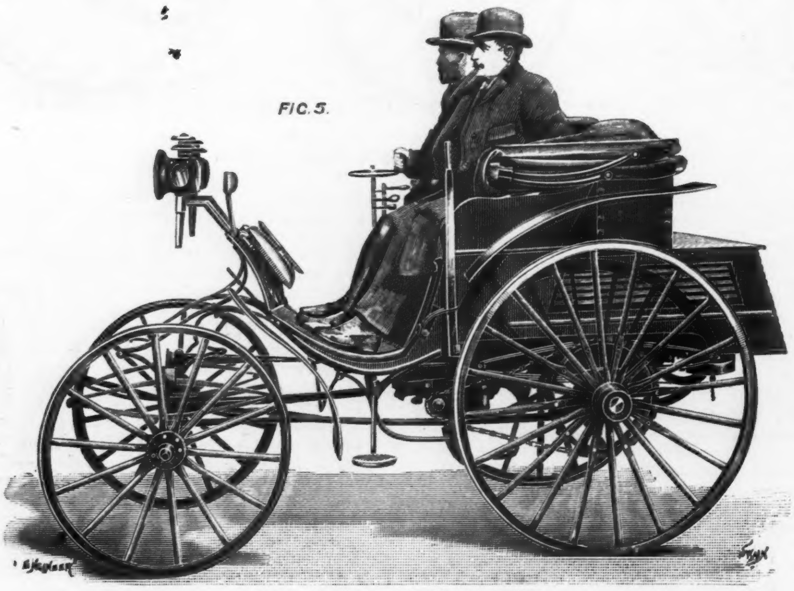
FIG. 6



THE LEWIS MOTOR CARRIAGE AT CHICAGO

(6) *De La Vergne motor carriage.*—This was another gasoline carriage, but it slipped its wheels so badly in the snow that the man in charge soon abandoned the race, and so ran the machine back to its shed after a short run of 1¼ hours. The carriage, as shown in Fig. 5, has four wheels, and seats two persons. It is fitted with a 4-horse power gasoline engine, having the cylinder and jacket cast in one piece. The engine runs at 350 to 400 revolutions per minute, a muffler stifling the noise of the exhaust, and a condenser disposing of unconsumed gas so as to prevent unpleasant odours. There are no belts, and the power is transmitted to the axle by a chain-and-sprocket wheel. The tank and exploding battery are under the front seat, the tank holding a three days' supply of gasoline. The engine and gearing are mounted complete in an iron frame ready to be fitted to the carriage, and the weight of the machinery is about 300 lb. About 30 lb. of water are required for the cylinder jacket for a run of ten hours. The total weight of the carriage is about 1000 lb. Some large hunting drags, seating six persons, have been built, weighing 1800 lb., and have two-cylinder engines. The engines are built by the De La Vergne Refrigerating Company, and the carriage bodies were supplied by different carriage builders. Five other competitors were expected to run in this race. Haynes and Apperson broke one of the wheels of their gasoline carriage in making a sharp turn to avoid a cable tramway car while on the way to the starting point. Max Hertel broke the steering gear of his gasoline carriage; and Banske and Brothers—gasoline—A. G. Ames—steam—and George W. Lewis—gasoline—could not get their carriages ready in time.

FIG. 5.

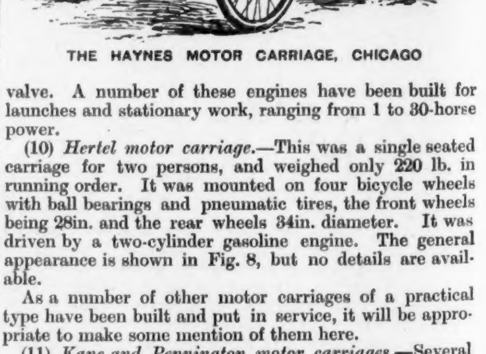


DE LA VERGNE MOTOR CARRIAGE

(7) *Lewis motor carriage.*—This is a four-wheel, single-seated carriage, which was built in December, 1894, and is fitted with a patent gas vapour engine invented by Mr. George W. Lewis, and quite extensively used for launches, stationary engines, &c. The engine is of 2-horse power, with a single vertical cylinder, and is placed in a case behind the seat, a chain connecting the sprocket wheel on the shaft driven by the engine with the larger sprocket wheel on the rear axle. A small generator and the battery which furnishes current for the igniting spark are behind the seat, while in front are the gasoline tank—which holds a supply for about 100 miles' run—and the six-gallon water tank for circulating water in the cylinder jacket. The fly-wheel on the engine shaft drives the sprocket wheel shaft by a friction pulley, there being slow-speed and high-speed gears, and the noiseless friction gears being of raw hide. The engine runs at 300 to 500 revolutions per minute, and the speed can be changed by the gears without affecting the speed of the engine. The front wheels are 32in. diameter and the rear wheels 44in. diameter, all built of wood and fitted with heavy solid rubber tires and roller bearings of special design. Iron braces maintain the spacing between the sprocket wheel shaft and the rear axle, and these braces are adjustable as to length so as to regulate the tension of the driving chains. The front wheels have pivoted hubs, with rods leading to a central vertical steering shaft having a goose-neck handle. The cost for fuel is said to be about ½d. per horse-power per hour. The weight of the carriage is 1250 lb., and its appearance is shown by the view in Fig. 6, which is taken from a photograph furnished by Mr. Lewis. A double-seated carriage of the same general type weighs 1500 lb., and is fitted with a 4-horse power two-cylinder engine weighing 450 lb. and developing 6-brake horse-power. The seats are placed back to back.

(8) *Haynes carriage.*—The first Haynes carriage was built in the winter of 1893-94, mainly for experimental purposes, and is shown in Fig. 7. It is a single-seated carriage for two persons, and weighs 1052 lb. in running order. It is mounted on four 28in. wire wheels, with 1¼in. solid rubber tires. The maximum speed is about ten miles per hour. The motive power is a 2-horse power gasoline engine, built by the Sintz Gas Engine Company, the power being transmitted by sprocket wheels and chains to a countershaft, and thence in the same way to the rear wheels. The carriage will run 50 miles at ordinary speeds with one charge of gasoline. A somewhat larger carriage, built for the Chicago competition—but which met with an accident, by which one of its wheels was damaged the day before the race—was a two-seated trap seating four persons. This weighed about 900 lb. in running order, and was mounted on four 36in. wire wheels fitted with 2in. pneumatic tires. A 4-horse power double-acting balanced gasoline engine, built by Haynes and Apperson, was used, and the power was transmitted in the same way as in the older carriage. In the Sintz engine the gas and air are mixed in the lower end of the cylinder—which opens into a chamber containing the crank space—and the mixture then passes to the closed upper part of the cylinder through a port which is opened as soon as the body of the plunger piston reaches the lower end of its stroke. The mixture is then compressed in the clearance space above the piston, and is exploded by an electric spark as soon as the piston has reached the end of its up stroke. The gas generator holds about a pint of gasoline, and the feed is regulated by an automatic needle valve. A number of these engines have been built for launches and stationary work, ranging from 1 to 30-horse power.

FIG 7.



THE HAYNES MOTOR CARRIAGE, CHICAGO

(10) *Hertel motor carriage.*—This was a single seated carriage for two persons, and weighed only 220 lb. in running order. It was mounted on four bicycle wheels with ball bearings and pneumatic tires, the front wheels being 28in. and the rear wheels 34in. diameter. It was driven by a two-cylinder gasoline engine. The general appearance is shown in Fig. 8, but no details are available.

As a number of other motor carriages of a practical type have been built and put in service, it will be appropriate to make some mention of them here.

(11) *Kane and Pennington motor carriages.*—Several carriages fitted with the Kane and Pennington gasoline engines were originally entered for the competition, and in view of what has recently been said about these motors in the English papers, it is to be regretted that none of the carriages actually ran. Figs. 9 and 10 give some details of the engine—Fig. 9 being reproduced from the *American Machinist*—while Fig. 11 shows the Elston

carriage, and Fig. 12 shows the Racine carriage, the former having a 4-horse power and the latter a 2-horse power Kane-Pennington engine. Ordinary gasoline or kerosene oil flows by gravity from the tank to the engine, and is exploded by an electric spark, the consumption of fuel being about $\frac{1}{10}$ gallon per horse-power per hour. The cylinders are drawn steel tubes, with spring rings to the piston. The $\frac{3}{4}$-horse power engine has one cylinder, the 2-horse power two, and the 4-horse power four cylinders. The following particulars of this much discussed engine are extracted from an article in the *American Machinist*, by Mr. Randol, who had seen the carriages and engines.

FIG. 8

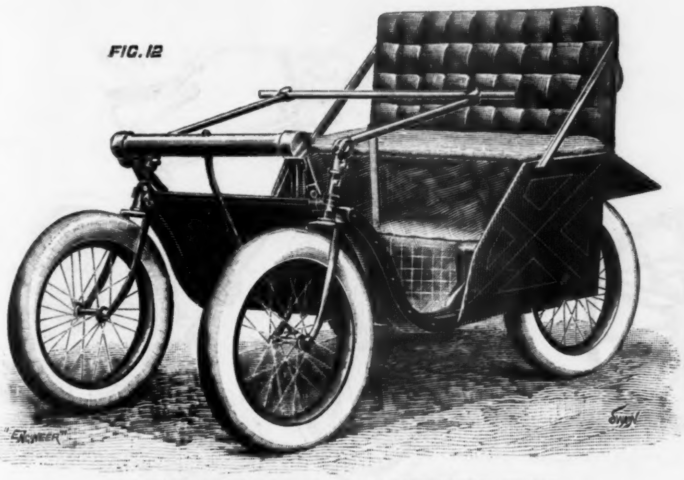
THE KANE-PENNINGTON GASOLINE ENGINE

FIG. 12



RACINE CARRIAGE WITH KANE-PENNINGTON ENGINE

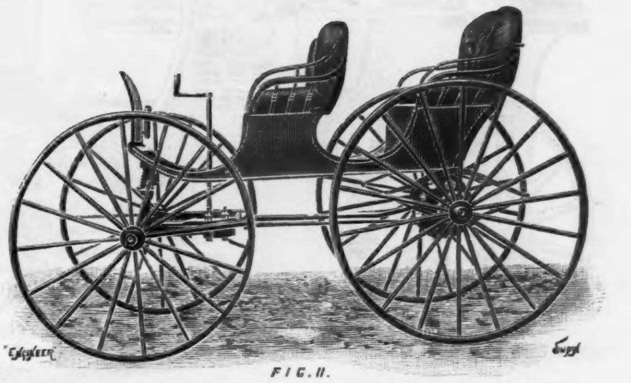


FIG. 11.

ELSTON'S CARRIAGE WITH KANE-PENNINGTON ENGINE

In some way, so far wholly unexplained, the great heat which in other explosive engines manifests itself as an inconvenient bye-product, to be taken care of as best it may, is in the Pennington engine transformed into useful effect on the piston. I know that when the long, thin first spark is not put through the charge the engine becomes weak and hot, and that when this first long, thin spark, this "mingling" or "ripening" spark, as Mr. Pennington calls it, is used, a common gas engine, with its carburetter eliminated, gives twice its ordinary effect on the crank. I know also that all the experts who have been employed by capitalists to examine this engine have been first incredulous and then amazed, and finally enthusiastic, and I have therefore decided to let this first paper stand as it is, because it correctly exhibits not only my own experience, but the experience of all others, both learned and simple, upon a first examination of the motor. This two-spark mechanism of the Pennington motor actually does not cost five cents, and yet when applied to the "Regan" gas engine, largely built up to the present time by the Kane establishment at Racine, it doubles the power of that motor. It is in the igniter, and in the double spark, or rather in the effect of the first spark, apparently, that the efficiency of the Pennington motor lies. In the Victoria, Fig. 12, the motive power is chain geared, with two reductions, first to an intermediate shaft, then to a variable speed shaft, and last, from the variable speed shaft back to the drivers, each wheel being independently driven, as there is no through shaft for either the rear or front wheels, the Victoria design being on strictly bicycle construction lines. The reduction from the engines to the driving wheels is 4 to 1 for the slow speed, and 2 to 1 for the quick speed. The upright hand lever has three positions; standing upright, the engines are disconnected from the driving wheels; hand lever to right gives 4 to 1 reduction to drivers; hand lever to left gives the quick drive, which is a 2 to 1 reduction from the motors to the drivers.

The Victoria engines have a fly-wheel, and the right-hand crank wrist is prolonged to form a handle; the intermediate shaft sprocket wheel is loose and may be clutched to the shaft by moving the upright lever. When not clutched to the shaft the engines run without moving the vehicle; to start the engines one complete turn of the engine shaft is made by hand, and it then continues to run from the action of the engines until either the oil or the spark-producing current is shut off. After the one revolution by hand the riders mount the seat, and a movement of the vertical lever clutches the sprocket to the variable speed intermediate shaft, and the Victoria at once begins to move.

The consumption of common kerosene oil per hour per horse-power indicated is about one-tenth of one gallon, or about two quarts per hour for $4\frac{3}{4}$-horse power. Pennington's 2-horse power motor weighs $17\frac{1}{2}$ lb., and his entire Victoria weighs less than 400 lb., of which perhaps 140 lb. or 150 lb. belongs to the motive power and reducing gear. It will easily transport a load of 800 lb., making a total weight of 1200 lb.

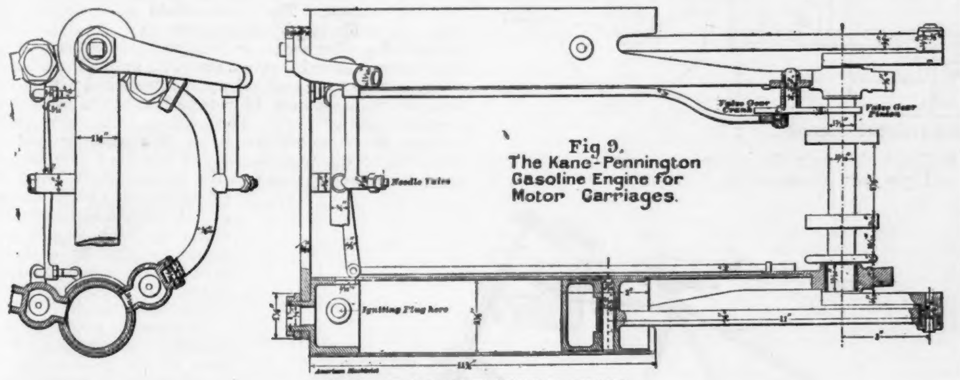

Fig 9.
The Kane-Pennington Gasoline Engine for Motor Carriages.

PLAN OF KANE-PENNINGTON ENGINE

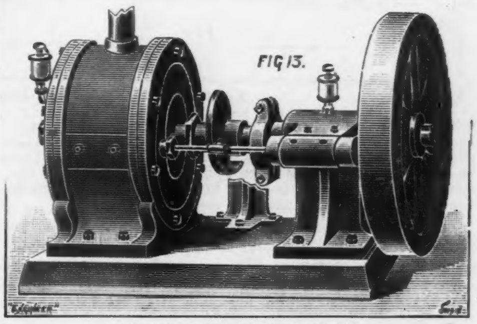
It will be observed that the cylinder proportions of the engine are not at all those common to gas engines, $2\frac{1}{2}$in. cylinder diameter by 6in. stroke forms the standard unit. But a much greater digression is shown in an engine now under test, having a $2\frac{1}{2}$in. diameter with 12in. stroke single cylinder, in which the terminal pressure is reduced almost to atmosphere, with a fuel gain of about 45 per cent. over the $2\frac{1}{2}$in. by 6in. cylinder dimensions.

Referring to Fig. 9, there is next to nothing in the way of description or explanation to give. The oil admission is simply a screw-controlled needle valve, which is very simple and gives no hint of its two-current refrigerating powers. The cylinders are made of steel tubes, ground inside in a primitive engine lathe, and steady rest rig, dry, and almost certainly not a very close approximation to a cylindrical form. The pistons, I was told, were drop forgings. They would be more easily made in grey iron. The piston rings are grey iron, less than $\frac{1}{16}$in. thick, with halved joining. The pistons and open cylinders appeared to be wholly free from any deposit, and were bright and clean. The trunk pistons are a very slack fit in the cylinders, perhaps $\frac{1}{32}$in. small. The workmanship generally was fair, and the designing was specialised with a very high degree of ingenuity, as I need not say when it is remembered that a 58 lb. locomotive—motor bicycle—made a mile in fifty-eight seconds on a street pavement.

The machine which made this run of a straightaway mile in fifty-eight seconds is shown in Fig. 17. To avoid the weight of reducing gear the diameter of the cycle wheels is dropped to 22in., and to give adhesion and avoid puncture the pneumatic tires are made 4in. diameter, after Pennington's specifications, and cannot be injured by a hammer and nail in skilled hands; the attempt to drive the nail into the inflated tire results in a simple rebound of the nail, the tire remaining intact.

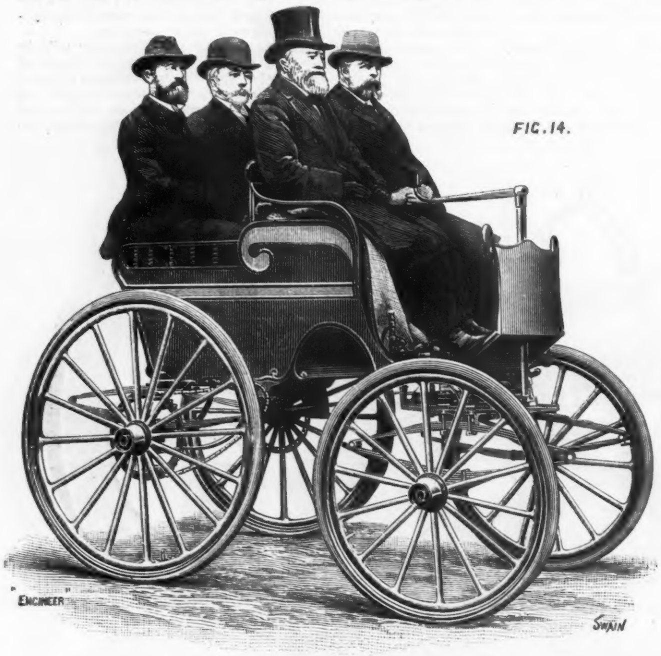
The passenger on the bicycle feels the impulse of each stroke of the engines, just the same as on a little stern-wheel steamer; aboard the Victoria the heavy fly-wheel equalises the motion, and the individual piston impulses are not distinguishable. The kerosene is carried in the long tube on the top of the dashboard, Fig. 12, and passes through the tubular framing of the body to the motors. The motors themselves are of the 4-stroke cycle variety, and make one outboard working stroke, and one inboard, idle, cylinder-clearing stroke, then an outboard charging stroke and an inboard charge-compressing stroke in sequence; the valve operating crank is driven by a pinion and spur 2 to 1 reducing gear on one side, with a cross lever transfer to the other cylinder. With the 6in. stroke cylinder the exhaust is very audible, though not disagreeably so. With the 12in. stroke cylinder the noise of the exhaust is not noticeable. There is no visible discharge of vapour, and no evident odour except in case of an over admission of oil, and an over admission of oil leads to an immediate loss of efficiency, which makes its continuance an impossibility. The one great mystery is the coolness of the naked cylinders, which should be red hot at the end of the first twenty strokes or so of a run. Chemists are familiar with the establishment of low temperature pressures, but pressures established by explo on are not cold as a rule, and the gas engine has always been hot.

FIG 13.



THE HARTLEY ROTARY ENGINE

The Kane-Pennington shops are making or have made general trials of the water-jacketed cylinder; the $2\frac{1}{2}$in. by 12in. expansion engine is jacketed and piped with top and bottom natural circulation pipes to a small water tank which a run of some length did not seem to heat very much. The cylinders run perfectly well naked, with no cooling element more than their inevitable exposure to the atmosphere. There is evidently some heat-absorbing or



THE HARTLEY STEAM CARRIAGE

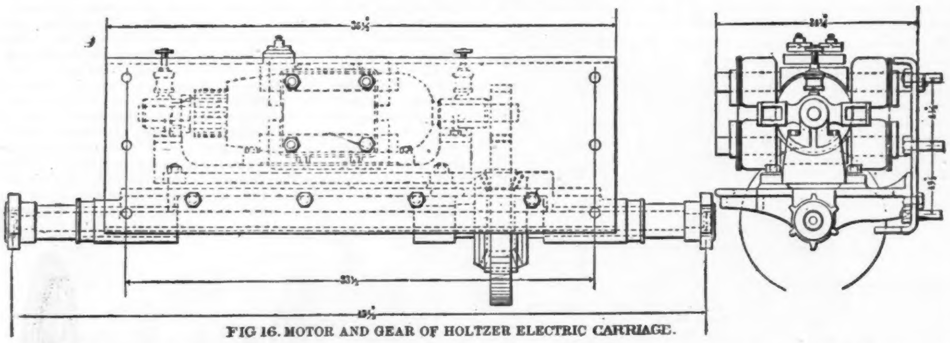

FIG 16. MOTOR AND GEAR OF HOLTZER ELECTRIC CARRIAGE.

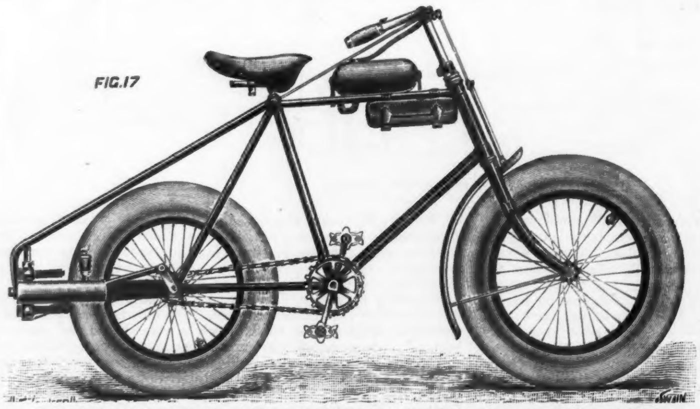
diverting or abstracting element or operation in the Kane-Pennington engine not commonly present in the gas engine, and it is difficult to see what this can be, if it is not the truth that the heat of the cylinder walls is absorbed by the incoming charge previous to the moment of the ignition, or else transformed into work on the piston, as it seems impossible that the gases after ignition should be otherwise than very hot indeed. Cards from the 2½in. by 12in. motor are promised, and these may give some clue to the thermal conditions of the Kane-Pennington motor in action.

(11) *Hartley motor carriage.*—This is one of the few steam motor carriages, and uses a rotary engine of the general style—shown in Fig. 13—except that a second cylinder replaces the fly-wheel. The carriage is shown in Fig. 14. It is mounted on 36in. front and 44in. rear wheels, provided with pneumatic tires and ball bearings. The weight is 500 lb., with 250 lb. more for the engine, boiler, and machinery. The boiler is 16in. diameter and 20in. high, placed at the front of the carriage, and the valve gear is operated by an excentric.

(12) *Holtzer motor carriage.*—A heavy drag, weighing 5100 lb., was built to order last spring by the Holtzer-Calvt Electric Company, and carries six or seven persons. The running gear is heavily and substantially built, and the wheels have ball bearings. The carriage and its machinery are shown in Figs. 15 and 16. The batteries are contained in the body and under the front seat, and the top of the body which supports the two rear seats is hinged, so that it can be thrown up, leaving the cells and all connections accessible for examination or repair. The batteries comprise forty-four chloride cells, 250 ampère hours, with a nominal discharge rate of 25 ampères. The cells are arranged in four groups of eleven each, and are connected to the motor through a series parallel controller, which puts the groups in multiple series, and multiple gear respectively, giving three speeds—5, 8, and 15 miles an hour. These are operated by the lever shown alongside the steering shaft, and locked in the various positions by engaging with a notched sector and spring latch. This arrangement gives three well-defined speeds, and no rheostat is needed. Though put to severe tests in climbing hills and running on heavy roads, the batteries have proved equal to the requirements. The body is made waterproof and painted with acid-proof paint, to prevent damage in case of the breaking or slopping over of a cell. The motor is a 4-pole series-wound of 7½-horse power capacity, and weighs 450 lb. Its speed at full load is 250 revolutions, and its efficiency 89 per cent. A phosphor bronze armature pinion engages with a carefully cut intermediate gear, the shaft of which is divided and connected through a differential gearing, allowing the wheels to run at different speeds when rounding corners. The intermediate shaft drives the hind wheels directly by chains, one on each side. The motor and gearing are protected by a light leather casing. For convenience in backing a reversing switch is mounted on the sector of the controller and interlocked with it, so that the motor cannot be reversed until the controller lever is placed at "off." The carriage lamps have each a 10-candle power electric light. The steering gear is connected to the movable hubs of the front axle, heavy crank levers being geared to the steering shaft, which is provided with a bicycle handle. A toothed segment with a spring latch is also arranged, so that by a slight pressure of the foot the operator may lock the front wheels at any angle.



MOTOR BICYCLE, WITH KANE-PENNINGTON TWO-CYLINDER GASOLINE ENGINE

This article would be incomplete without some reference to the application of motor engines to bicycles and tricycles, in which line a great deal has already been done.

(13) *Kane - Pennington motor bicycle.*—The bicycle shown in Fig. 17 has been described above in the description of the carriages and engines of the same firm. It has a 22in. driving wheel, with two cylinders at the back end of the frame. In the tandem machine the frame extends forward beyond the front handle bar of the single machine shown. Still another machine, of the style

shown, has vertical cylinders behind the rear wheel, driving a horizontal shaft projecting beyond the top part of the frame and carrying a silk-bladed screw propeller. This third machine weighs 58 lb.

(14) *Riotte motor bicycle.*—This is an ordinary bicycle with an oscillating cylinder, having its piston-rod attached to a crank disc on the rear axle. Oil is exploded in the rear of the piston, the small tank on top of the frame carrying a supply sufficient for 75 miles run. The weight of motor, oil and battery is only 9 lb. A speed of 20 miles per hour has been made on a good level road, and fair speeds up grades of 4 per cent. This machine is shown in Fig. 18.

(15) *Maxim motor tricyle.*—The machine shown in Fig. 19 is a tandem tricycle, fitted with a three-cylinder engine of the Otto cycle type, leaving only one-sixth of the revolution without impulse. The cylinders are of cold-drawn seamless steel tubing, $\frac{1}{16}$in. thick. The battery for the exploding spark is under the rear saddle, and has nine chloride cells, weighing about 12 oz. The gasoline tank holds a supply for 60 miles, and is under the frame. The motor weighs about 32 lb., and the whole machine not more than 100 lb. The power developed is 1½-horse power. This machine was built by H. P. Maxim.

(16) *Simonds' motor velocipede.*—The machine designed and built two years ago by C. L. Simonds is shown in Fig. 20. It has a porcupine boiler with 28 square feet of heating surface, and carrying 100 lb. pressure. Naphtha is the fuel, and a supply sufficient for 100 miles run is carried. The engine has two cylinders, with cranks set at 90 deg., and the rear axle is driven by a sprocket wheel and chain. The machine can run at ten miles per hour, and can ascend grades with two passengers. There are two pumps, one to feed the boiler, the other to blow the air blast through the naphtha. Under the boiler are five burners, so arranged that they can be used singly if desired. The exhaust steam passes through a feed-water heater, and is then delivered to the naphtha flame, where its presence stifles the noise. The total weight is 450 lb.

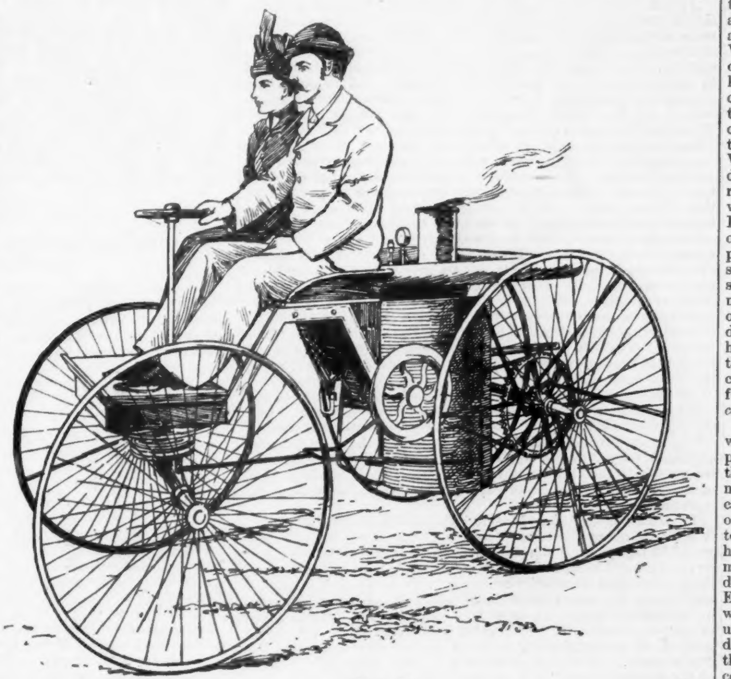


FIG. 20.
SIMOND'S STEAM MOTOR VELOCIPEDE

(17) *Motor delivery carts.*—Finally there is the application of mechanical power to small delivery carts of the form made by the Benz Co.—worked by the driver—are now being extensively used, and to which power has already been applied experimentally. In the Tinklam cart the driver sits with his back to the box, while in the Warman cart he sits facing the box.

It will be seen by what has been said in this article that there are in actual use a number of motor carriages of different types, and the competition run conclusively proved that some of them are capable of service under extremely unfavourable conditions. The impulse which has been given to the motor carriage within the past few months has had the inevitable result of deluging the Patent-office with a flood of applications for patents on motor carriages and carriage motors, and it is said that over 500 patents have been issued since the first announcement of the competition. Probably only a small number of these are of any practical value, but from the practical interest which has been shown by carriage builders, motor builders, &c., it is pretty certain that many important improvements will be introduced, and the motor carriage made a commercial as well as a scientific and a mechanical success.

One important result of the introduction of such carriages in the United States will be to increase very forcibly the growing demand for good roads. The great army of bicyclists and persons interested in making, selling, and using bicycles has already done a great deal in securing the construction of proper roads in certain districts, and in forwarding the "good roads movement" generally. This will now be reinforced by those interested in making, selling, and using motor carriages. Persons using horse carriages have been largely apathetic, from the reason that horses can go almost anywhere, and these persons have to be educated up to the point of seeing the expense and trouble incidental to driving or hauling on bad and muddy roads.

THE ENGINEER IN NAVAL WARFARE.

In this country many writers have produced many books more or less romantic dealing with naval warfare as it is supposed that it will be in the future. It is a noteworthy fact that none of these writers have handled the subject from the engineer's point of view. We hear the voice of the captain, the artillerist, the torpedo man, and the artist, but the engineer has been silent. We come across the statement that "Mr. Cross-Head maintained steam at full pressure," but no one thinks of saying how. We are told that "Mr. Side Lever, finding one of his engines blown to pieces by a shell, effected repairs in three hours, and just saved the ship from capture," but there is silence as to the details of this wonderful operation. In a word, the engineer has been virtually ignored. But there is more than this. It is indisputable that in naval warfare the engineer's department will play the most important part; but hitherto the engineer has been allowed to say very little as to his wishes.

Now, in the United States naval engineers think very much as they do in this country. They are treated with scant justice. One man has, however, carried the war into the enemy's camp, and delivered a series of lectures at the Naval War College at Newport. As an introduction to what follows, we quote here from the New York *World*:—

"During the summer a problem of great national interest was discussed at the Naval War College at Newport: How should the Navy of the United States be manœuvred, in event of attack upon the New England coast by a superior fleet of British vessels? Able officers were called upon to furnish plans of defence and to tell what should be done in the hour of great danger. These plans were laid before the college in the form of lectures, in which the writers, with full knowledge of the powers of our various vessels, discussed all the intricate phases of the problem. Among those detailed to a plan of defence was John R. Edwards, of the Engineer Corps, one of the most brilliant officers in the service. He wrote in a popular style, and so mercilessly exposed weak spots in our present organisation of the navy that his lectures raised a storm in the service, which has not yet subsided. Every effort was made to prevent these lectures from reaching the public, but repeated appeals to Secretary of the Navy Herbert have secured them for the *World*. The Secretary, after reading the lectures himself, concluded that they were of such general interest that he overruled the official objections to their publication."

We give Mr. Edwards's first lecture in a slightly condensed form. It will be seen that he has had to deal with certain assumed conditions laid down for him, much as conditions are stated for the admirals carrying out our own naval manœuvres.

PROBLEM.

May 10th.—War is imminent. The enemy is assembling at Halifax. He is expected to descend upon the New England coast. His probable plan is to occupy the coast and chief cities from Portland to Boston, thereby seconding certain movements of his land forces. His success depends upon his completing this occupation before June 10th, and maintaining it until July 10th. The force destined for this purpose is one or more fleets whose total is three times that of our fleet, and 20,000 men in fifty transports. Our available force is ordered to assemble for the present in Nantucket Sound.

May 20th.—War is declared. A fleet leaves Halifax, occupies Provincetown, and blockades Boston May 23rd. Is composed of six battleships, eight armoured cruisers, eighteen cruisers, twelve gunboats, aud twelve torpedo boats. Gains and keeps touch with our fleet, wherever it may be, by means of scouts. Our force is five battleships, five armoured cruisers, fifteen cruisers, ten gunboats, ten torpedo boats, and one ram. A heavy monitor at Boston, a light one at Portsmouth, and another at Portland are to be retained at those points. We learn that a much larger force of the enemy is about to leave Halifax. It sails thence May 25th, blockades Portland, occupies Casco Bay, and gains touch with its Provincetown fleet May 27th. Is composed of ten battleships, fifteen armoured cruisers, twenty cruisers, twenty gunboats, twenty torpedo boats, and fifty transports carrying 20,000 troops of all arms. Design plan for meeting this demonstration. Show best disposition of our forces, and describe in detail our preparations for the campaign.

Mr. Edwards, in answering this problem, devoted his first lecture to the work of naval engineers before going into action. He, in fact, tells the story of what he assumes would happen, as though the events had really taken place. He said:—

Qualities of command.—Early in April the Secretary of the Navy and the admiral commanding the defence fleet had several protracted consultations with the Engineer-in-Chief in regard to the threatening aspect of affairs on the New England coast. Imperative orders were given the Bureau of Steam Engineering to put the machinery of every war vessel in the highest state of efficiency. Unlimited expenditures were authorised, and instructions given to effect such alterations as would make each vessel a most reliable fighting machine; but every improvement suggested in any vessel had first to receive the approval of the admiral in command. The Commander-in-Chief of the defence fleet in urgent terms requested the Engineer-in-Chief to nominate as fleet engineer an officer who possessed the following requirements:—Ready in resource and of engineering constructive ability; not over forty-five years of age, yet quick of judgment and with a broad knowledge of the plans of our various types of ships; capacity for work, and rare executive ability; with considerable sea service, and great love and knowledge of his profession; of some personal magnetism; and of great will power and fixedness of purpose. Nearly every chief engineer on the active list applied for this duty, but by reason of age their requests were denied. It was urged by the admiral, who was under fifty-five years, that no one of any staff corps who had served in the last war should, on account of their age, do active work at sea. Line officers might go as a commander of a vessel, but then they should only be sent on battleships and armoured cruisers, or as flag officers. It was recalled to mind that Admiral Farragut's fleet engineer was only thirty-three years of age when the forts below New Orleans were passed, and in looking across the sea it was observed that the English Admiralty only appointed as Engineer-in-Chief of their great and powerful navy a comparatively young man. Of course, they are continued in office when they show matchless talents for the work.

The age of the fleet engineer.—Some difficulty was found in securing a man to fill the post of fleet engineer. It was regarded by the Secretary as next in importance to that of a fleet captain. An examination of the January Register showed that every man on the chief engineer's list was beyond the age limit set by the admiral. With great earnestness the Engineer-in-Chief urged that the admiral's wishes be respected in regard to the request for a fleet engineer. The old officers insisted on being sent. A very able fleet engineer was ordered, who was over fifty years of age. Within two weeks he physically collapsed under the great strain of almost continuous day and night work. During that period he had rendered invaluable service to the fleet, and some of the changes made under his supervision had an important effect upon the result of the great naval battle fought off the Massachusetts coast. His successor was one of the young officers who had been trained under the personal supervision of the Engineer-in-Chief. With such a preceptor, it was but natural that he had acquired decision and quickness of judgment, and a confidence which was ready to assume great responsibilities. Thoroughly conversant with the definite policy which had actuated the work of the Bureau of Steam Engineering, he knew the strength and weakness of our ships so far as their structural arrangements and motive power were concerned. Incessant work for a dozen of years in studying marine engineering questions, both at the Bureau and at sea, made him no stranger to the duties before him. He had made one cruise at least as a virtual chief engineer, although the official records showed that he served as assistant. Within a few days the Commander-in-Chief was impressed with the fact that in his fleet engineer he had a most valuable assistant. Casting aside the traditions of the past, he showed himself a great man by overcoming the prejudices of his four decades of naval life. Into his full confidence this fleet officer was taken, and then he was given *carte blanche* to prepare for the inevitable battle.

Changes in the cruiser.—Here are some of the changes that were wrought:—One of the scouts were sent for several hundred bunker plates and frames of standard size, so that the upper bunkers of the several ships could not only be coaled more rapidly, but be made more habitable in action. Under the direction of the carpenter the holes in the deck planking were cut to a size scant of that required. Another scout was sent to the nearest seaport to Lynn to bring men and electric drill outfits for cutting additional holes in the protective deck. Doors for closing the openings thus made were ordered from Bethlehem and Pittsburg, the detail drawings having been made by one of the assistant engineers. Emergency chutes which opened directly into the several fire-rooms were built within the bunkers. These extended from above the upper bunkers through the protective decks, and had suitable doors for preserving the water-tight features of the vessel. To the great joy of all the gun crews, the deck pumps were disconnected and all sent to a navy yard, where they took up valuable room in one of the buildings, thus robbing the scrap-pile of its legitimate prey. The valuable space secured by the removal of these pumps was utilised in many ways. And the capture of one of the enemy's cruisers was due to the fact that one of our vessels was able to prolong the chase for several hours by reason of carrying thirty additional tons of coal in jute bags in the space formerly occupied by the deck pumps. Those pumps might have been of use when all the boilers were in one compartment. If the boiler space had then become flooded the deck pump might have been of service. But in a modern ship, where the boilers are in several compartments, it is not likely that all the fires are going to be put out at once. If such a calamity should occur, the quicker the crew took to the boats the better. Those who would remain with the pump would probably find a watery grave.

Increased height of smoke pipes.—Additions were made to the height of all the smoke-stacks. This excited some comment, as it was supposed that we already had tall funnels on our vessels. An examination of the Marblehead, a vessel which was said to have been ruined in appearance by her tall stacks, showed that their tops were only 57½ft. above the grate. Those who made a cruise in the Chicago previous to 1895 hardly recognised her with her new and tall stacks. In the eyes of the admiral she was beautiful with these tall shafts, for he knew that this was a mark of efficiency and that it increased her sea speed. The cruising speed of the fleet was materially assisted by this action and the efficiency improved. The fleet engineer gave warning in regard to the enormous quantity of top hamper with which only too many of our battleships are oppressed. An Engineer editorial of June 5th says:—"We have deck-houses and bridges and boats and cowls. These would be converted in five minutes by machine and quick-firing guns into matchwood. Probably this matchwood would be set on fire. No wooden structure of any kind should be permitted on the upper deck. This was the lesson of the Yalu. As to the funnel, it is clear that with anything like a smooth sea and a moderate range, machine guns could cut these off pretty short. The cowls and ventilators would be reduced to small scrap. The existence of a warship as an antagonist must depend in action on her fans, and we have never yet been on board a man-of-war in which the fan arrangements appeared to be the best possible." The blower arrangements were improved, but not to the extent that could have been done if more time had been given. Temporary provision was therefore made for the ventilation of the vessel should the ventilators be cut away by small shell. The vital wind shafts were so arranged that nothing the enemy could do would affect them. Was it not strange that the ventilating question had to be settled on the eve of battle?

Quality of the fuel.—An inspection by the fleet engineer of the bunkers of the several ships showed that they contained various kinds and qualities of coal. There were anthracites, containing from 2 to 14 per cent. of ash, and there were even mixtures of the red and white ash varieties. There were bituminous invoices which had been exposed to the weather, and whose hydrocarbons had in great part volatilised and passed off. There was even a quantity of fuel which resembled peat more than it did coal. The sizes varied from steamboat to barley buckwheat. He knew that the efficiency of the vessels would be impaired by the possession of such fuel, for in action, when it would be necessary to force the fires to their utmost, there will be no time to select coal. That within reach would be taken, and a mixture of the various inferior kinds found by the fleet engineer in the ships would have resulted in the rapid formation of clinker, which would contain a large percentage of unconsumed carbon, thus not only entailing a great waste of coal, but decreasing the efficiency of the boilers. This investigation resulted in a Board of Naval Engineers being appointed to determine the quality and character of the coal supplied to our war vessels on the Atlantic coast. Repeatedly during their many consultations the Engineer-in-Chief had impressed the admiral with the superiority of our vessels in "boiler power" over that of the enemy. It was shown that in battle our vessels would be kept moving, and that the enemy would be given no chance of preparing for a rush at full speed under forced draught; that our ships, with larger boiler power and with their increased ratio of grate surface, would be in an efficient state when those of the enemy would have their fires full of clinker, tubes choked, and firemen exhausted. Taking them class for class, our ships are more powerful in their machinery than the ships that will operate from Halifax. The accompanying table shows that the Indiana and Massachusetts are but slightly inferior actually to the battleships of the Royal Sovereign class; but, as our vessels are of considerable less displacement, it will take about 20 per cent. more power to give the first-class battleships of the enemy the same speed as the Indiana class. This they have not; and so it may be confidently accepted that so far as sustained speed is concerned our ships are at least equal to the best that the enemy can concentrate. When it comes to the Iowa, we have a ship that in boiler power is far superior to anything that can be brought against her in the battleship line, and is only inferior in boiler power to the armoured cruisers of the enemy. Coming to the armoured cruisers, the Maine, though larger than the vessels of the Australia class, is shorter and not such a good form for speed; but she has greater boiler power, and may be expected to maintain nearly, if not quite, as good speed as the Australia class. The New York is fully 15 per cent. more powerful than the Blake, and the Brooklyn has practically the same power as the Blenheim, so that the ships we have of this class are not at all inferior to those of the enemy. Coming down to the protected cruisers it will be seen that the Columbia and Minneapolis have fully 75 per cent. more boiler power than the first-class cruisers of the Edgar class, and while they will be of greater displacement when fully loaded, they are in point of speed and endurance unapproachable by any vessels of the enemy's fleet. The Olympia, though much smaller than any of the hostile first-class cruisers, has greater boiler power than any of them, and is, therefore, capable of doing any duty in scouting or raiding that could be expected of a ship in possession of the enemy, and owing to the superior design of her boilers, she could do this duty much more economically than could the ships of the enemy.

Comparison of the Boiler Power of Vessels of the U.S. and British Navies.

	Displacement.	I.H.P.	Grate surface.	Heating surface.	Ratio of heating to grate sur.
Royal Sovereign Class	14,900	11,500	731	20,348	27·8
Indiana	11,600	9,000	616	19,195	31·1
Iowa	12,000	11,000	756	24,038	31·8
Australia Class	5,600	8,835	514	15,502	30·1
Maine..	6,800	9,292	574	19,015	33·1
Blake	9,000	14,525	871	27,192	31·2
New York..	9,000	17,400	1052	32,958	31·3
Blenheim	9,000	21,411	1135	31,073	27·4
Brooklyn	9,000	17,000	1016	33,429	32·9
Edgar Class	7,700	10,517 12,851	812	24,908	30·7
Columbia	8,100	18,500	1408	45,221	32·1
Minneapolis	8,100	20,860	1520	50,147	33·0
Vulcan	7,000	12,062	564	15,861	28·1
Texas	6,800	8,600	582	19,912	31·8
Mersey Class	4,050	6,151	388	11,565	29·8
Charleston	4,050	6,666	436	15,577	35·7
Forte Class	4,360	9,274	575	15,641	27·2
San Francisco	4,300	9,913	577	20,135	34·9
Archer Class	1,770	3,754	222	6,836	30·8
Yorktown Class	1,800	3,400	220	8,092	36·8
Medea Class	2,900	9,268	526	13,264	25·2
Cincinnati Class	3,550	—	617	20,179	32·7
Apollo Class	3,550	9,274	575	15,641	27·2
Palas Class	2,600	7,469	410	11,025	26·9

Machias	1,200	1,800	120	4,590	38·2
Royal Arthur	7,700	10,086	731	24,828	33·9
Olympia	5,800	17,000	828	28,300	34·3

It will be particularly noticed that in the three types of vessels in which the plans were purchased abroad we have not that marked superiority over our transatlantic cousins in horse-power.

Flooding compartments.—An inspection of the fleet showed that in some of the vessels no provision had been made for flooding every compartment. Fire is an element which will have to be fought by the crews of a war vessel, and the occasion may arise when a compartment will have to be flooded to save a ship. This was one of the lessons taught at the Yalu. An exceedingly able writer in one of the June numbers of *Harper's Weekly* speaks as follows upon this subject:—"When the fires began to burn fiercely on some of the Chinese vessels it was found that there was no means of flooding the compartment where the torpedo heads were stored preliminary to being brought into action. This was an added source of danger, and it became necessary to throw the torpedoes overboard at once. It is probable, as a result of this, that further improvements will be necessary in the construction of warships to avoid such action in danger." Without going into dock flood-cocks were attached to the hull and pipes fitted, and the defect of not being able to fill the compartments with water was overcome. Everything was subordinated to placing the boilers and engines in a state of maximum efficiency, for the Engineer-in-Chief had convinced the Secretary of the Navy that in a modern war vessel the motive power had become a weapon, and that for special purposes it was superior to the gun. Speed, and particularly its control, is the cardinal element of tactics. Ability to manœuvre is now more dependent upon the number, form, and position of the propellers and the shape of the hull than it is upon the skill of the commander. They are therefore the qualities and attributes of a weapon. But the motive power is more. It is a defence, and in many respects of more importance than the armour. It gives the commander the option of avoiding or forcing a contest, and with marked superiority in speed he may determine the strategy of the battle. There are other ways of rendering a ship useless than by killing the men at the guns. Continuous work in an ill-ventilated and contracted fire-room will cripple the efficiency of that steam weapon below the protective deck. That voyage of the Columbia across the ocean is going to be fraught with great results. What mysterious power suddenly gave our people confidence when they read of the splendid run of the matchless "pirate?" It was because the nation had a glimpse of the future, and was told that speed was *par excellence* the weapon of the ship of war. Those pillars of fire at night and those clouds of smoke by day which belched forth from the funnels of the Columbia between the Needles and Sandy Hook settled the speed question of our war ships for the remainder of this century. Those who think our ships go too fast are likely to find out that our people believe such critics move too slow. And those who complain of the excessive horse-power of our vessels will find few people to argue with them.

Floating workshops and repair ships.—There had been fitted out for the use of the defence fleet two floating workshops, or repair ships. They were called the Corliss and Fulton. The men in charge of the several tools had been so instructed and drilled that in case of the capture of the repair-ship some vital part of each machine could be disconnected very readily. The ships were in great part fitted with duplicate machine tools, in order that the continuance of any special work need not be interfered with, and in case it was found necessary to sink one of the vessels to prevent her from falling into the possession of the enemy one could still be available. The workmen were nearly all members of the New England Naval Reserve, and probably had no superiors in the world as rapid and skilful artisans. Trained in the use of small arms and rapid-fire guns and subservient of discipline, their work and conduct received the special commendation of the Commander-in-Chief. All repairs were made under the direction of a naval engineer, who had as his assistants some of the ablest mechanical engineers in New England. These men had voluntarily offered their services until the close of the war, and their patriotic employers had sent with them to the repair-ships the pride and pick of their several establishments. The equipment of the repair-ships was placed absolutely in the hands of the engineer-in-chief. In general it may be said that the outfit was of such a character that it was capable of fitting up any casting from a two-ton cupola. Any plate whose width was less than 48in. could be handled successfully, irrespective of length. Particular care was taken that the repair-ships were not loaded down with too many tools. They were not intended, nor was it possible, to make them floating dockyards. The impracticable suggestion to equip them in a manner resembling a ship-construction plant was not seriously considered. Plates which could not be conveniently handled aboard such a ship were too large to be manipulated anywhere except at a great shipbuilding plant.

Auxiliary naval repair stations.—As the usefulness of a repair-ship is greatest for service abroad, or when the fleet is operating at some distance from its base, the Navy Department, after mature deliberation, decided upon another method of making the ships efficient. The Secretary therefore ordered the engineer-in-chief to co-operate with the admiral in command, and to make the necessary arrangements to establish repair stations. The American Society of Mechanical Engineers and the Marine Engineers' Beneficial Association of the United States, through their executive officers, called upon the President and tendered their services, requesting particularly to work under the special direction of the engineer-in-chief. It was realised by the President that our only hope of success—with our naval force but one-third as powerful as that of the enemy—was in having our fleet maintained in the highest state of efficiency, so that our maximum force could be utilised for a decisive blow at almost any hour. Six of the best-appointed engine plants in Rhode Island, Connecticut, and Massachusetts which are accessible to the sea were turned into auxiliary naval repair stations. There the great bulk of the repairs of the fleets were made. Whenever the repair was of a small but important nature, but beyond the resources of the fighting-ships, orders were given in different shops to make several of the parts required. The new pieces were sent aboard by different despatch-boats, and it was quite certain that at least one part would reach the vessel it was intended for. The fire and engine-room watches of all the vessels were drilled and trained, so that each of the enlisted men could do the duties of the next higher rating. As a victory was looked for, the fleet engineer thus provided in part for future contingencies. He thoroughly realised the fact that the engineer's force would be well employed and under great pressure before, during, and after the battle. The collapse of many good men could therefore be expected, and provision had to be made for such casualties.

To man a captured ship.—He knew also that in the case of victory it would be reasonable to anticipate that some of the enemy's ships would be captured. Such ships would either have to be destroyed or prize crews placed on board to take them to an American port. Such crews must necessarily contain a large proportion of officers and men of the steam department, which could not be arranged under existing circumstances without crippling the fighting power of our own vessels. A very decided improvement was made in the method of communicating between the conning-tower and the engine-room. Changes were made in the size, shape, and location of the mouthpieces of the speaking-tubes. Additional mechanical telegraphs were installed, likewise a simple, reliable bell-pull. Those contrivances of the dreamer which may be a success of the morrow, but which are unreliable toys of to-day, were discarded. Suitable key-words for certain work were agreed upon. When it was found necessary to pass orders by word of mouth, single expressive terms which could not be misunderstood were employed. Our enemy had also swept from their decks the worthless contrivances for communicating with the engine-room, for a London engineering leader had warned them as follows:—"For example, what is the use of an elaborate series of speaking-tubes from the forward conning tower to the engine-room, down which no intelligible message can be transmitted, given under ordinary conditions when the engines are running, and which would be utterly useless in the noise of an action? What can be said in favour of electrical signalling arrangements which cannot be trusted even on a peaceful cruise? The engineer would take very good care to provide signalling arrangements which, if they did not permit the captain and the chief engineer to consult with each other, would not fail to tell the latter what the former wanted the engines to do." The fleet engineer and the several chiefs had given serious consideration to the best method of arranging the fire and engine-room watches. The admiral and his council of commanders, after mature deliberation, had decided that the organisation of the engine force could best be done by the chiefs of the respective ships. In general it was determined to arrange the watches as follows:—First, when chasing, or escaping from an enemy, or when making maximum speed for a protracted period, the men should be placed in two watches, so long as this did not continue beyond thirty-six hours. This was terrible work, when taking into consideration the circumstances under which the men lived. After battling with fires forced to their utmost, it was impossible for men to sleep and rest until they were freed of the strain and excitement. In order to have the men secure some rest between the watches, it would be necessary to work them six hours at a time. For a long voyage the men should be placed in three watches and then relieved of all drill and routine duties.

Too few coal handlers.—The chiefs of all our vessels have been urging that the coal passers be taken out of the powder division. In an official report the chief engineer of the Columbia wrote:—"The force of firemen and coal passers is not sufficient for natural draught, steaming with all boilers, except when coal is very convenient to the fire-room." This is what the chief engineer of the Chicago wrote upon the same subject:—"I deem it my duty to state that the *personnel* is entirely too small to admit of the proper care of the machinery and utterly inadequate to sustain the proper efficiency of the engineer department during an engagement. One-third of the department being transferred to the powder division leaves many important stations, such as stop valves, bearings, &c., without special attendance, which will lead to serious disaster during battle." Captain Mahan comments thus on this report:—"The above representation of the chief engineer shows, in my opinion, the necessity of a general consideration of the question of actual necessities of an engine-room in action. The efficient working of the powder division of the Chicago required that deduction from the engineer force." Is it not possible to help matters, both in the engine-room and on deck, by improving the arrangement of magazines, and the manner of supplying and hoisting ammunition? Surely some better way can be found than the present methods. The great weakness of the Columbia and Minneapolis, besides the arrangement of their coal bunkers, is the method of supplying ammunition, and if this defect were overcome the powder division could do more efficient work with fewer coal passers. More men could then be secured for the fire-room, where there would be urgent duties for them to perform.

Station bill when in action.—It is not probable that a naval conflict in the future will be prolonged beyond six hours. For that period, and for an hour or two before and after the battle, the entire engineer force will have to work continuously. Improvements can and should be made in the manner of supplying ammunition. If this were done, the powder division with one-sixth the engineer force could do better work than they now accomplish. Two-thirds of the force should be stationed in the engine and boiler compartments. With one-sixth on deck helping to supply shell to the guns, there would then be a remaining sixth to form an "emergency watch," which would be under the charge of an assistant engineer. This squad would look out for the fire hose, stop valve gear on deck, make repeated examinations of the bunker water-tight doors, observe the operation of every steam and hydraulic machine outside the engine and boiler rooms, inspect at intervals the leads of the steering gear, stand by to work the steering appliance from below if the deck gear should be carried away, be in readiness to effect temporary repairs or overhaulings to any inefficient or disabled auxiliary. As they would be picked men they might be able to render effective aid should any of the gun mechanism jam. It is almost impossible to tell of the many possible ways in which their services could be utilised. Mechanics are not to be found aboard a ship in the deck force. I have never seen a good vice hand outside of the engineer department aboard any of the fifteen ships that I have been attached to. There have been excellent blacksmiths, but they were neither capable nor anxious to do the work of either boilermaker or machinist. I am quite positive that, during the three years I was aboard the Petrel, we never had target practice without having some slight hitch in the breech mechanism of one of the 6in. rifles. This was not the fault of the guns, but it was due to stupid work on the part of some Wallabout recruit or Asiatic "beach-comber." Therefore, the usefulness of the "emergency watch" is vast in its possibilities, and if these men could have special drills in dismounting guns, &c., they might become an important factor in helping to determine the result of a battle. In the short space of time that was permitted to prepare for battle, the development of electric power for many purposes, suggested in the engineer department, could only in part be carried out. No better authorities on the question can be found than S. Dana Greene and W. S. Shallenberger, both formerly of the naval service, and the absence of some of the motors recommended by them was greatly regretted on all the ships on the day when they went into action and met the enemy.

PRODUCTION OF PIG IRON IN THE UNITED STATES IN 1895.

WE estimate the production of pig iron in the United States, in 1895, at 9,387,639 gross tons. This estimate is based upon the monthly blast furnaces reports made to the *American Manufacturer*, and published in our columns. These reports of production for the first eleven months of the year, 1895, with an estimate for December are as follows:—

Production of Pig Iron in the United States in 1895.

Month	Production. Gross tons.
January	705,329
February	619,317
March	697,144
April	668,713
May	691,216
June	701,567
July	772,423
August	833,256
September	860,130
October	938,498
November	934,449
December, estimated	965,597
Total	9,387,639

The estimate for December is on the basis of the daily production of November, that is, 31,148 tons a day, or 965,597 tons for 31 days. Owing to the special conditions at the close of the year, it is probable that production in December will hardly be up to the average for November, but the difference will be slight.

As to the probabilities of this estimate being correct, we need not speak to those who know so well the accuracy of these monthly reports. To those who do not, we may say that the statements are based on actual returns. For the first six months of the year the production, as shown in the above table, was 4,083,286 tons. The report of the American Iron and Steel Association gave a production for the same time of 4,087,558 tons, a difference of about 1-10 of 1 per cent.

The production of pig iron in 1895 is the largest year's production in the United States, the nearest approach to it being in 1890, when 9,202,703 tons were made. The yearly production of the United States since 1885 is as follows:—

Production of Pig Iron in the United States, 1885 to 1895.

Year	Production. Gross tons.
1885	4,044,526
1886	5,683,329
1887	6,417,148
1888	6,489,738
1889	7,603,642
1890	9,202,703
1891	8,279,820
1892	9,157,000
1893	7,124,502
1894	6,657,388
1895, one month estimated	9,387,639

As compared with 1894 there was an increased production in 1895 of 2,730,251 tons, or 41 per cent.

The production of the two halves of 1895 were as follows:—

	Gross tons.
Production 1st half 1895	4,083,286
Production 2nd half 1895	5,304,353
Total	9,387,639

That is, the production in 1895 has increased day by day until at the close of the year it is nearly a million tons a month.

Unless Great Britain shall greatly exceed any previous year's production, this is the largest year's production of pig iron in any country in the world. In 1882, the year of its greatest output, Great Britain made 8,586,680 tons. The make of the United States in 1895 will be 800,000 tons in excess of this. The make of Great Britain in 1894 was 7,364,745 tons.—*American Manufacturer.*

LORD ARMSTRONG ON MR. EDISON.—Replying to a correspondent, who had asked him his views regarding some alleged recent statements by Mr. Thomas Alva Edison as to his invention of instruments of destruction for service in war, such as ærial infernal machines, engines throwing water charged with electricity, improved water torpedoes, and a gun for the firing of dynamite, Lord Armstrong, writing from his seat in Northumberland, says:—"Cragside, Rothbury, December 27th, 1895. Dear Sir,—If the words attributed to Mr. Edison are correctly reported, which I greatly doubt, I must say that this great inventor is both hard to understand and extravagantly sanguine. Designs which exist only in idea are seldom of much account, and Mr. Edison would be more than human if his brain were capable of evolving matured inventions, of astounding potency in war, requiring no protracted trials to fit them for practical application. In such matters, models and laboratory experiments go for very little on this side of the Atlantic. Nothing short of trials on a scale of actual practice can be relied upon, and these, if made, would, from their nature, be incapable of concealment, so that the advantage of sole possession would speedily vanish. Transcendent inventions, even when coming from an Edison, should always be received with incredulity in the absence of tangible proof, and Lord Salisbury is himself too much of an electrician to be moved from his serenity by any threats of wholesale electrical destruction which Mr. Edison, in the fervour of his patriotism, may have uttered.—Yours sincerely, ARMSTRONG."

RAILWAY MATTERS.

The average speed of the Empire State express on the New York Central Railroad is now 53¾ miles per hour, while the average speed of foreign expresses is given as follows:—England, 51·75 miles; Germany, 51·25 miles; France, 49·88 miles; Belgium, 45·04 miles; Holland, 44·73 miles; Italy, 42·34 miles; and Austria-Hungary, 41·75 miles.

A locomotive boiler exploded on the Southern Railway at Emery Gap, Tenn., on December 13th. The engine was standing on a side track at the time, in charge of the fireman, the engineer and conductor having gone to the railway office for orders. The fireman was seriously injured, as was also a bystander, who was 100ft. away from the engine, and who was struck by a flying piece of iron.

An electric motor suit, covering the patents on the mounting of electric motors on car axles in such a way as to enable the gearing to drive the axle without transmitting shocks to the motor, has been brought by the Adams Electric Railway Company against the Lindell Railway Company, of St. Louis. Mr. Wellington Adams, one of the promoters of the defunct Chicago and St. Louis Electric Railway scheme, claims that his patents cover this method of mounting car motors, which is used by many companies.

A steel rail tramway for country roads has been proposed by Mr. John O'Donnell, of Lowville, N.Y., formerly State Railroad Commissioner, to facilitate traffic of wagons and other road vehicles. The rails are about ¼in. thick and 5in. wide in the tread, with a rib or flange about ½in. high on each side, the flanges also extending below the flat part of the rail, and being spiked to the longitudinal timbers upon which the rails rest. These timbers rest upon cross-ties on the sub-grade of the road, and gravel or broken stone is filled in up to the level of the rails. The cost of finished road is estimated at £600 to £1000 per mile, the latter being for a good macadam road. The timber and steel tramway is estimated to cost £500, the balance being for the paving.

Four railroad cars that made their first appearance in the Connellsville region last week coming over the Baltimore and Ohio Railroad are regarded as the beginning of what may revolutionise the designs and uses of freight cars. Each car was a combination suitable for the transportation of grain, coke, coal, stock or fruit. The construction is such that by the temporary removal of every other board in the sides of the car, a load of grain or stock can be brought east and a load of coke be taken west on the return journey. The bottoms of the cars are drop doors for the unloading of ores and fuels. The Campbell and House patent is employed. The *American Manufacturer* says, the cars were built at the South Baltimore Car Works, and are fitted up with air brakes, patent couplers, and all modern improvements. They were constructed by the Chicago and Blue Island Railway.

The Cornish mail train had a very narrow escape from being wrecked on the 27th ult. morning after passing Doublebois Station. The passengers were alarmed by a loud rumbling and violent jolting, which increased until the train stopped. It was then found that the engine, one of the Great Western Company's new powerful type with front bogie, had left the rails and dragged after it the first coach, an empty one. The accident occurred within a short distance of the St. Pinnock Viaduct, and the passengers, in realising the nature of their escape, highly commended the action of the driver, who brought the train to a standstill by the prompt application of the vacuum brake. The mails and passengers, who were shaken, but otherwise uninjured, were despatched to their destination by special train, and the line was cleared during the day.

A lift-span 421ft. long is proposed for the New Kansas City and Atlantic Railroad bridge across the Missouri River at Kansas City, Mo. The bridge is to occupy masonry piers and abutments built some years ago, and will have two 421ft. spans, one of which is the lift span. For this lift span steel towers will be erected on the piers, and the moving span or deck will move vertically up and down between them, its movement being effected by means of counterweights travelling up and down in the towers. The whole arrangement and operation is much like that of an ordinary window sash and its counterweights. *Engineering News* says:—It is calculated that eight men can operate the bridge by hand, and that the same can be accomplished mechanically by a small motor. The total lift of the span is 45ft. They will provide for a double-track railway 32ft. wide, a roadway 11½ft. wide on each side of the railway, and a sidewalk 5ft. wide on each side of the bridge, making the total width of the span 65ft. The bridge was designed by Mr. J. A. L. Waddell, M. Am. Soc. C.E.

Considerable interest was manifested in an experimental trip recently made on the Great Eastern Railway to ascertain what, if any, difficulties there would be in the way of running a through train from London to Cromer without stopping, if it should be decided to put one on. Owing to the number of severe gradients, junctions, curves, &c., together with a swing bridge, and a portion of the road being a single line, no very high speed is possible, but it was hoped that the distance of 138 miles could be covered in three hours. The engine selected was one of the company's standard single-wheelers, No. 1006, having 7ft. driving wheels, 4ft. leading and trailing wheels, cylinders 18in. by 24in., 1217 square feet of heating surface, 18 square feet of grate area, working at a pressure of 160 lb. per square inch, and weighing in working order 40 tons. *Moore's Monthly Magazine* says, the engine was fitted with a tender on six wheels, 4ft. diameter, carrying 3100 gallons of water, and weighing with coal and water, 35½ tons. The train consisted of eleven main line coaches, weighing in all about 140 tons. Thus the total weight to be hauled was at least 215 tons. Sunday, November 3rd, 1895, was fixed for the trial, and on that day the experimental train left Liverpool-street at 11·35½ a.m. Cromer was reached at 2.31, the whole distance having been accomplished without a hitch of any kind in 175½ minutes, or at an average speed of over 47 miles per hour throughout.

It is announced that Mr. Francis P. Cockshott, the superintendent of the Great Northern Railway, has just retired after fifty-five years of active service. The excellence of the Great Northern services to Lancashire, Yorkshire, and Scotland has been largely due to him, and his life may be said to be an epitome of English railway history. As a schoolboy he often rode on the footplate of "No. 1" of the Stockton and Darlington. He was on the first ship that ever entered Middlesbrough Docks. While yet in his teens he became private secretary to Mr. Edward Pease, M.P., treasurer of the Stockton and Darlington and Great North of England Railways, and in that capacity often attended meetings between Joseph Pease and George Stephenson. From Darlington, after a short training in the engineering shops at Shildon, he went to Scotland as goods manager and superintendent of the Edinburgh and Northern, afterwards known as the Edinburgh, Perth, and Dundee, whose trains from Leith were hauled up by a stationary engine through the Scotland-street Tunnel—now abandoned, the *Times* says, to mushroom growing—into the then new Waverley Station in Edinburgh. In 1851 he went to the South Devon, where the atmospheric system had only recently been abandoned. In 1858 he took charge of the Cornwall Railway also. There it was his lot to conduct Brunel, lying on his back on a carriage truck, to see for the first and last time his great Saltash Bridge completed. There, too, the intervention of a director, who urged him not to work himself to death, dragged him from the footplate of an engine which half an hour later ran off the line on a viaduct near St. Germans and buried itself and its crew in the mud of the Tamar. In 1865 Mr. Cockshott came to King's Cross to take up the position which he held until Tuesday last.

NOTES AND MEMORANDA.

According to a return of the cost of power in the Antwerp Exhibition of 1894 by gas, oil, and steam engines, it was the same for gas and for steam for engines of 50-horse power, namely, 0·49d. per indicated horse-power, producer gas being used. For 10-horse power it was also the same, namely, 1·06d. per indicated horse-power, but for 2-horse power it was 2·93d. for gas, 1·74d. for oil, and 2·91d. for steam. The small steam engines were thus very expensive steam pipe obstructions.

The *Electrical Engineer* says that on January 1st, 1895, the Edison Electric Illuminating Company had connected 7615-horse power of electric motors, but at the end of October it had no less than 11,263-horse power, an increase of 3648-horse power in the short period of ten months. The horse-power capacity thus connected includes, it would seem, a great many of the fan motors, but not all, as it is becoming a common practice for people to plug the small motors into lamp sockets without fuss or notice, and, of course, these do not appear on the returns. The company has 251,487 incandescent lamps connected and 3280 arcs. This would figure out in the neighbourhood of 25,000-horse power, so that one-third of the company's total connected capacity is now represented by motors.

At a recent meeting of the Geological Society, a paper on "The Alteration of certain Basic Eruptive Rocks from Brent Tor, Devon," was read by Frank Rutley. The author gave a detailed account of the microscopic characters of sections of rocks from Brent Tor, and discussed the history of the rocks, comparing them with Tertiary basic glass, and with the Devonian rocks of Cant Hill, which he described previously. He brought forward evidence in favour of the view that the original alteration of both the Brent Tor and Cant Hill rocks was palagonitic, and that while in the Brent Tor rocks the subsequent alteration of the palagonite into felsitic matter, magnetite, secondary felspar, epidote, and probably kaolin, and some serpentine and chlorite was complete, it was only partial in the case of the Cant Hill rocks.

Underground electric locomotives at the Marles colliery, in the Pas-de-Calais, each weighing three tons, draw thirty corves holding 15 tons of coal, at the rate of 16 kiloms. = ten miles per hour, thus taking the place of thirty horses. Of the two Saint-Augustin shafts, A and B, 4m. = 13ft. in diameter, at No. 5 seat of working, each shaft is provided with a vertical winding engine, one of 200-horse power and the other of 250-horse power. The A shaft has landings at depths of 210m. = 114 fathoms, and 260m. = 142 fathoms; and shaft B is fitted with rail guides and electric signalling apparatus. The whole Marles concession, which covers 2990 hect. = 7388 acres, has three other seats of working, all situated at Auchel, seat No. 3 comprising the Saint-Firmain and Saint-Abel shafts, and No. 4 the Saint-Emile shaft, 4m. = 13ft. in diameter, with its air shaft of 2½m. = 8ft. 3in.

At the last meeting of the Chemical Society a paper was read on "The Composition of the Limiting Explosive Mixtures of Various Combustible Gases with Air," by Frank Clowes, D.Sc. A series of experiments were made with mixtures in varying proportions of each combustible gas with air. A flame was brought into contact with each mixture, sometimes above and sometimes below, and it was noted whether the mixture burnt back independently of the external air. For each combustible gas there was thus obtained a lower percentage below which the mixture would not burn independently, and a higher percentage above which the gas burnt independently only when it was supplied with more air. The limiting percentages were as follows:—For methane, 5 and 13; for hydrogen, 5 and 72; for carbon monoxide, 13 and 75; for ethylene, 4 and 22; for water gas, 9 and 55; for coal gas, 5 and 28. It was also proved that many mixtures which were outside but close to the above limits, and which could not be fired from above, could be fired from below. Hence it is inferred:—(1) That the limiting explosive mixtures for different combustible gases vary widely. (2) That methane shows the narrowest limits, hydrogen the widest limits. (3) That the risks of a mixture being fired explosively increases with the different gases in the following order:—Methane, ethylene, coal-gas, water-gas, carbon monoxide, hydrogen. (4) That the risk of explosion is greater when the mixture is kindled from below than when it is kindled from above.

Last year's production of iron ore in Sweden amounted, according to the *Sveriges Officiela Statistik*, to 1,926,524 tons, being 445,036 tons more than in 1893, and that of manganese ore to 3359 tons. The quantity of iron ore put out, which shows an increase of 30 per cent., has never before been attained. The principal mine, Gellivare, which contributed 655.401 tons last year, against 306,594 tons in 1893, is followed by that of Grängesberg, with 401,513, against 261,865 tons. Moreover, the iron content of the ore put out increased from 54 per cent. in 1893 to 64·4 per cent. last year. Although the use of lake and bog ore is decreasing yearly, 689 tons were utilised in 1894, bringing up the total iron ore production to 1,927,212 tons. Last year 462,809 tons of pig iron were turned out, being 9388 tons more than in 1893. There was a falling off in the out-turn of iron blooms and billets, and also in that of Bessemer steel ingots, the respective quantities of which were 204,517 tons and 803,296 tons; but, on the other hand, there was a great increase in the production of steel ingots by the Siemens-Martin process, the quantity of which was 81,714 tons, being an increase of 1893 tons. Only 464 tons of crucible cast steel were produced, showing a diminution of 54 tons. Iron and steel bars, 146,786 tons; and iron and steel hoops, 78,092 tons, both show an increase, the last-named description especially, and while the 28,764 tons of wire rods show a falling off, plates, 10,850 tons, show an increase. The blast furnaces turned out an annual mean of 3192 tons each; and on an average each furnace remained in blast during 257 days in the year. The mean daily out-turn of a furnace was 12·43 tons. Charcoal practically constituted, as heretofore, the only fuel used; but for the production of a small quantity of spiegeleisen a little English coke was added.

An improved calorimeter, for the application of the method of mixtures in determining specific heats, is described by Mr. F. A. Waterman in the *Philosophical Magazine*. Mr. Hesehus's ingenious suggestion is acted upon, to maintain the calorimeter, after the introduction of the heated body, at a constant temperature by means of cold water, instead of measuring the rise of temperature of the calorimeter. This arrangement gets rid of the radiation error, and eliminates the "water equivalent" of the vessel. By dropping the cold water in, stirring is also made unnecessary. The method has been placed by Mr. Waterman upon a footing of equality at least with other methods, but his success may be partly due to other improvements. The body experimented upon is heated by a coil of wire conveying a current, and surrounded by ice. The initial temperature of the body may thus be regulated by simply maintaining the current at a certain strength, and this temperature can be kept constant for five or six hours together to within 0·1 deg. C. The body is then plunged into a silver calorimeter surrounded by the bulb of a delicate air thermometer indicating a difference of temperature of 0·01 deg. C. The cold water is contained in a copper vessel having the shape of an inverted cone surrounded by ice. In this manner the ice cannot melt away and leave a free space round the vessel. The water-dropping arrangement and the electric heater are mounted on vertical axes in such a manner that they can be quickly swung into position just over the calorimeter. After the heated solid or liquid has been dropped in, the warter-dropper is set to work, at first rapidly, and then slowly, until the body has assumed the original temperature of the calorimeter. For bodies of the same weight and the same initial temperature, the specific heat is then, *Nature* says, simply measured by the amount of ice-cold water necessary to cool them to the temperature of the room.

MISCELLANEA.

Oil fuel is to be tried on board the torpedo destroyer Daring in the forthcoming mobilisation of the vessels of this class.

We understand that Messrs. Siemens have ordered a very large feed thermal storage vessel, on the Halpin system, for their Woolwich works.

Science Progress for December contains, among other articles, "Theories of Electrolysis," "The Study of Ancient Sediments," and on "Mineral Transformation."

Messrs. J. and G. Thomson, of Clydebank, have been commissioned by the Spanish Government to construct two torpedo boat destroyers to attain a speed of 28 knots, while having on board a load of 75 tons. They are to be somewhat larger and of stronger scantlings than those built for the British Navy.

Models representing each type of warship of the United States navy are being made at the Washington navy yard. Seven men have been constantly employed for some time past in constructing these models, which cost from £200 to £1600 apiece. The model of the fast cruiser Columbia, now under way, is only 5ft. long.

A board of American experts, headed by Admiral Walker, has recommended, says the *Army and Navy Gazette*, that the rams in the new battleships Nos. 5 and 6 be placed 11ft. below the water-line, as in the Texas, in accordance with the English system. The Bureau of Naval Construction, in its plans for these vessels, placed the rams 5ft. below the line.

The coal shipping returns for the past year show that the clearances of the Scottish ports amount in the aggregate to 7,479,940 tons, compared with 5,341,012 in 1894; 7,928,994 in 1893, and 7,764,417 in 1892. The large shipments in 1893 was the result of the prolonged strike in the coal trade of the English Midlands, while the great falling off in 1894 was due to the four months' strike of the Scottish miners.

A test of mechanical filters is proposed in connection with the waterworks of Minneapolis. Mr. F. W. Capelen, city engineer, is reported to have been in correspondence with manufacturers of these filters, with a view of having 250,000 gallon plants of the various systems set up for an experimental test of six months' duration, without further expense to the city than the furnishing of power to such plants as require it.

Her Majesty's Consul at Bilbao has advised the Secretary of State for Foreign Affairs that the corporation of that city are prepared to receive tenders up to noon on January 30th, 1896, for the construction of a portion of the main sewer, the engineer's estimate for which is about £5738. Plans, estimates, specifications, and forms of tender for this work may be inspected at the Sanitation Department of the Bilbao Town-hall.

The Dismal Swamp Canal is to be reconstructed, and contracts are already awarded. This canal, built under a charter of 1787, extends from Norfolk, Va., to Elizabeth City, N.C., a distance of 48½ miles. The present width of 32ft. is to be increased to 60ft., and the depth is to be 10ft. throughout. The five locks will be reduced to 3ft., and the summit level will be cut down 7ft. The Deep Creek and South Mills locks will be 250ft. by 40ft., with 12ft. lift.

The Union Steamship Company's Royal mail steamer Scot, which left Southampton on the 21st ult., with the South African mails, put into Vigo on the 25th, having encountered very heavy weather in the Bay of Biscay, which appears, a daily contemporary says, to have loosened some bolts connected with the casing of the propeller shafts, necessitating the employment of a diver, who had to be brought from a distance, and whose services could not be secured for several days owing to the holidays.

The following public notice is posted at the railway stations between Waterloo and Hampton Court:—"One Pound Reward.—Lost, a black leather Despatch Case, with brass lock, marked, 'A. S., Admiralty,' containing a copy of the Navy Estimates for 1895-96, and a few official papers, but nothing of any negotiable value. It was left in a first-class carriage of the twelve o'clock night train from Waterloo to Hampton Court, on Saturday, October 19th, 1895." £1 reward is not likely to fetch this document.

The new Factory Act came into force on Wednesday. A notice calling attention to its requirements was posted on that day at all police stations and post-offices in the United Kingdom. The requirements specially mentioned are those which apply outside the factories and workshops already on the inspectors' registers—namely, the provision requiring all workshops to be registered; the provisions as to out-workers' list, and as to infectious diseases, which apply to persons giving out work to be done at the workers' homes, whether the place where the work is given out be a workshop or not; and the provisions as to accidents, which now apply to all workshops, including those in which only men are employed. The Home-office has issued ten separate abstracts showing the provisions of the law applicable respectively to textile factories, non-textile factories, workshops, white lead works, print and dye works, steam laundries, hand laundries, docks, wharves, &c., buildings in course of construction, and domestic factories and workshops.

On the 13th ult. a new suspension bridle bridge over the river Wye at Sellack, near Ross, was opened. The bridge has been erected on the site of the old ferry, and connects the parishes of Sellack and King's Caple. The engineer was Mr. Louis Harper, A.M.I.C.E., of Aberdeen. The bridge is composed of steel wire ropes of suspension type, with vertical rods, 2ft. apart, connecting the upper and lower ropes. The sides are protected by oak skirting and lattice panelling. The bridge has a camber of 3ft. It is supported by four cast iron columns 25ft. high, and is held up by anchor blocks and rails, secured by concrete. The clear span of the bridge is 190ft.; its total length, including approaches, being 228ft. It has a walking way of 6ft., and is 6ft. 10in. out and out. The flooring is of oak, overlaid with boarding of oak cross-pieces 1¼in. thick. There are red sandstone abutments—the material having been obtained from Sellack quarry—with forest stone coping. The bridge is 25ft. above the summer water level, and is 6ft. higher than the highest known flood level. The cost has been £900.

Notice is given, that on and after the 1st day of January, 1896, the lighthouse at the Admiralty Pier, Dover, and the light exhibited therein, and the bell sounded at the end of the Admiralty Pier, during foggy weather, will be altered as follows:—The existing lighthouse, coloured red, situate on the south side of the turret at the end of the Admiralty Pier, will be removed. The new lighthouse is situate on the north-western angle of the Fort carrying the iron turret at the end of the pier, and is of granite, and is surmounted with a lantern, painted white with a red top. The height of the Stone Tower of the new lighthouse is 23ft. 3in., and the wind vane at the top of the lantern is 36ft. 10in. above the glacis of the Fort at the end of the Pier. It has been designed by Mr. A. T. Walmisley, the engineer to the Dover Harbour Board. The height of the new light will be 55ft. at high water ordinary spring tides, instead of 44ft., the height of the light to be discontinued. The light will be a white fixed light, of 360 degrees horizontal range, with flashes at intervals of 7½ seconds, and has been supplied and fixed by Messrs. Chance Brothers, of Birmingham. The light will be dioptric, and will be exhibited from sunset to sunrise, and will be of the fourth order instead of the sixth order, and will be visible in clear weather at a distance of ten miles or thereabouts, instead of six or seven miles. A bell will be continued to be sounded in foggy weather, giving single strokes at intervals of 7½ seconds, but the bell will be larger and more powerful than that used at present.

FREE LABOUR ON THE CLYDE.

OWING to the Christmas holidays, which in the North run well into the New Year, there is necessarily a suspension of hostilities just now on the Clyde and at Belfast. The shops would be shut in any case for stock-taking, &c., and, consequently, day-to-day news on the subject of the dispute has been scarce. The daily papers are full of wars and rumours of wars, financial panics, and so on, and the engineers' strike has naturally been lost sight of to some extent. But it is there for all that, and this apparent calm is, it is to be feared, merely one of those lulls which proverbially precede the storm. The storm, too, will be a serious one, unless the Amalgamated Society of Engineers see fit to give in at the termination of the holidays.

Early in December we ventured to predict that outside intervention at that time would be unavailing; and, although we were almost alone in adopting this view, the result of the recent Conference has proved that it was the correct one. Personally we should have been very glad had our forecast proved erroneous, for anything which will tend to put an end to these disastrous struggles is to be welcomed. But though the efforts of the Lord Provost of Glasgow, the Lord Mayor of Belfast, and Lord James, were exceedingly praiseworthy, neither the masters nor the trade union leaders were ripe for conciliation, compromise, or concession. The masters formally put into words the offer—which every one knew beforehand—they were willing to make, and the union leaders recommended the men not to accept it. When the men decided by vote to follow the advice of their leaders, the public became very indignant with them, for it was admitted that the masters' offer was reasonable. But the public have failed to realise the influences which were brought to bear on the men to induce them to record their votes against accepting the masters' terms. If, however, we take the trouble to look below the surface, and examine the circumstances under which the voting was carried out, a very strong side light is at once thrown on the motives of the men.

It will be remembered that the offer of the masters, roughly speaking, represented a shilling a week rise for the Belfast men, and two rises of one shilling each for the Clyde men. The Union officials straight away took the vote in Belfast, and their argument with the men was that the latter would be fools to accept a shilling advance when the Scotchmen had been offered two. The men thought that there was an injustice somewhere, and voted energetically against returning to work. But as a matter of fact the masters' offer was reasonable enough, for on the Clyde wages are much lower than at Belfast, and even with the two-shilling rise in the former locality the difference will not quite be made up.

The voting on the Clyde was held over until the result at Belfast was declared, and this at once strengthened very materially the hand of the agitators in that locality. But, apart from this, they had already a strong case, or one, at all events, which they knew would appeal to the men very strongly. They told them that if they wished to return to work at once, only a very few of them would be able to be taken on before the holidays, and this was perfectly true. Engineering shops which have been idle for some time can only be re-started gradually, however busy the masters may be. So the agitators pointed out to them that the result of voting for the masters would mean that they would get neither wages nor strike pay for the best part of a month, for if some were taken on during the fortnight up to Christmas they would all be without employment for the fortnight which followed. Now, as hundreds of the unfortunate strikers had been living with their families on from 8s. to 12s. a week, and such credit as they could get for the last two months, and the highest pay that any of them had received was 16s. a week, they naturally did not care to face the best part of another month with neither strike pay nor wages. So those who went to the poll—rather over half the total number—nearly all voted against the masters' propositions, while the others were afraid to vote at all.

It is notorious, however, that the real feeling of the men on the Clyde is to return to work, and after the holidays, when the considerations above referred to will no longer hold good, one may expect that this feeling will at once become much more manifest. The masters have been aware of it, at all events for some time past, and of late their deliberations have in a great measure been devoted to discussing the best methods of adequately protecting such of their men as may wish to resume work.

It is the old history of the shipowners and waterside labourers repeating itself in the engineering trade, and while engineering masters have not at the present time an organisation on the lines of the Shipping Federation, the policy adopted by the Amalgamated Society of Engineers is fast driving them in that direction. Working men will always throw in their lot with a powerful trade union if the masters also encourage the leaders of that organisation, and after all there is no reason why they should not, provided it is well managed and is carried on in the interests of the men. In practice, however, it has been shown over and over again that the men will stand at the hands of a trade society injustice and tyranny of a worse character than the hardest of masters would ever dream of applying, even if the law would allow him to do so. But there comes a point at which the pressure put upon the Union member by his officials is too strong even for the most docile of his kind, and under such conditions he decides to join hands with the masters if the lattter are willing. This has taken place often enough of late years, and in each case where both sides have acted loyally, capital and labour have in co-operation succeeded in getting along and in vanquishing their common enemy the trade agitator. So far, in the engineering trade, this sort of arrangement has only been carried out between isolated firms and their men. The present strikes will therefore afford the first instance of an association of engineering masters actively attempting to protect their men from a trade union.

It is stated that very strong preparations are being carried out for the protection of the men who wish to return to work after the holidays, and that sleeping accommodation is already being supplied on a large scale on the premises of more than one firm. That the masters are right to give their men a chance in this way there can be no doubt; but it is a sign of the times that, to enable an English workman to accept work on his own account, and earn an honest livelihood with comparative safety, these elaborate and costly precautions should be necessary. It is also significant that this should be happening in a district where hitherto the masters have habitually encouraged unionism by dealing only with the society officials when any question as to labour arose. Up to the present they have ignored the non-unionist; but now, at all events, they seem prepared to offer him his due. And the justice of this policy is obvious, from the moment that it is clear that the union officials no longer represent the feelings of the men.

It is now admitted very generally that these strikes originated in a bid for popularity on the part of the more pronounced "new unionists" among the labour agitators of the society; and it is urged in some quarters that something of the sort was necessary to draw attention away from the bad financial state of the Amalgamated Society of Engineers. Were these strikes to be successful, no doubt this Union would materially strengthen its hold over the men, and be able forcibly to increase its levies and subscriptions, for a time at all events. From all accounts this Union is sadly in need of an impetus of some sort at the present, for it is no secret that, in spite of its large income, it has been living on its capital for some time past, and, to put it clearly, is in one sense in a state of insolvency. Some few weeks back a full financial statement was drawn up by an actuary who from time to time has had to examine in detail the affairs of this society, and the contents of his report have found their way into the Press. From it we learn that the money in the hands of the whole of its branches at the present day would not suffice to pay much more than 10 per cent. of its liability under its superannuation fund alone. Had subscriptions remained at 1s. a-week, its liability would amount to no less than 2½ millions sterling; but by dint of raising the subscriptions to 1s. 6d., and by unjustly lowering the superannuation grants and increasing the age at which their members became entitled to receive their pensions, the society's net deficit stands at the present day at the appalling figure of nearly 1½ million pounds. This deficit in its funds is not a legal liability, and the unfortunate men who for years have been putting their money into what they believed to be a solid fund, have no redress now that it turns out that the fund has practically vanished.

It is perhaps encouraging to be able to say that Mr. Alfred Sellicks, the president of the Amalgamated Society of Enginners, left London on Tuesday for Belfast, to take part in negotiations which it is hoped will lead to a settlement. Mr. Sellicks has gone as a representative of the executive of the executive council of the society, with full power to treat with the employers on behalf of the engineers.

Under such circumstances it is high time that the masters should step in and endeavour to come to some sort of an understanding with their men in the trade, whether unionists or not. For a trade society which has so wantonly squandered the money of its subscribers cannot possibly be said to represent the interests of its members, and the men's destinies ought not to be left in its hands. Whatever the result of the present disputes may be, they will at all events have served to have opened the eyes of both masters and men as to the hollowness of an organisation which, under the title of the Amalgamated Society of Engineers, has been held up as a model trade union. What then must be the conditions of less perfect organisations of the kind?

SIR EDWARD HARLAND

SIR EDWARD HARLAND.

IN our last impression we gave a short account of Sir Edward Harland's life. We now publish a portrait which will we have no doubt be regarded with melancholy interest by a very large number of our readers. The circumstances of his death were very sad. Sir Edward had been in excellent health. He retired to rest about 11 p.m., and when half undressed he had a fainting fit from which he never rallied, passing away quietly very early on Christmas morning. He leaves no children. The news of his death was received with the utmost sorrow in Belfast and the neighbourhood, where Sir Edward was very popular.

THE LANARKSHIRE AND DUMBARTONSHIRE RAILWAY.

THIS line, extending from Stobcross, in Glasgow, to Dumbarton, a distance of 13¼ miles, is now well advanced towards completion, and affords every indication of being ready next summer for goods traffic, and a little later for passenger traffic. A glance at the map of Scotland at once shows the importance of the new route to Bowling and Dumbarton, which was commenced three years ago, and which will give access to Balloch by the joint line to that busy tourist terminus.

The principal works on the new line are the canal diversion at Bowling, now completed, with the exception of the 70ft. span swing bridge for carrying the railway traffic across the entrance to the canal.

The foundations of the swing bridge are completed, and the superstructure is finished in the girder yards of Sir William Arrol and Co., Glasgow, ready for erection at site. The boilers are in position, and the engines—by the Glenfield Co., Kilmarnock — are also erected beneath the arches of the viaduct connecting the swing bridge with the line.

A feature of interest are the two tidal culverts near Dumbarton, each formed of concrete, and having four 15in. tidal flaps to permit the drainage of the land above the line, whilst preventing flooding by the incoming tide. Each tidal culvert is furnished with an overflow safety wall, which permits a high tide to pass over it and flood the land above the railway rather than cause damage by excessive pressure on one side of the embankment only.

The remaining work of interest is the extensive additions and alterations now in progress for Dumbarton Station, where, owing to the character of the foundations, care is needed. The line is well provided with sidings. At Whiteinch a parallel line of siding is being laid down 2¼ miles in length, at lower level, and connected with the numerous shipyards at this point. At Dumbarton a siding is under construction into Messrs. Denny's shipyard. Numerous bridges of small span occur on the route by Sir William Arrol and Co., Arrol's Bridge and Roof Co., both of Glasgow; by Messrs. Alexander, Findlay, and Co., Motherwell; and by Messrs. Somervail and Co., Dalmuir.

The permanent way, which is now nearly completed, is in accordance with that adopted on the Caledonian Railway, viz.:—90 lb. rails, 45 lb. chairs and sleepers 2ft. 8in. apart, each creosoted with three gallons of oil. The engineer is Mr. Charles Formam, M.I.C.E., with Mr. J. Wolfe Barry, C.B., as consulting engineer. The resident engineers are Mr. C. R. L. M. Bond and Mr. John Ferguson, the contractors being Messrs. Robert McAlpine and Co. and Messrs. Hugh Kennedy and Sons, both of Glasgow.

THE MANCHESTER ASSOCIATION OF STUDENTS OF THE INSTITUTION OF CIVIL ENGINEERS will have their ninth annual dinner on January 22nd. Mr. J. Wolfe Barry, C.B., F.R.S., a vice-president of the Institution, has promised to attend. These anniversaries are attended by many of the older members of the Institution, resident in Manchester and the neighbourhood. Sir Edward Leader Williams, President of the Association, will take the chair.

AN OLD BATTLESHIP.—On the 22nd December the old naval reserve ship Castor, which has recently been replaced by the modern cruiser Medusa, took her departure from North Shields for Sheerness in charge of two powerful tugs. The Castor was for many years a familiar object in Shields harbour, and formed a picturesque relic of the obsolete type of man-of-war vessel. Built in 1821, the Castor is therefore seventy-four years old, and during the early part of her career she passed through a number of stirring experiences. She took part in the bombardment of St. Jean d'Acre, when several of her crew were killed and many wounded. Shields harbour has been the resting place of the Castor for the last thirty-four years, and during that lengthy period her alarm guns have thundered forth some scores of times, startling the inhabitants on both sides of the river with the unwelcome news of shipwreck.

ELECTRO-PNEUMATIC AUTOMATIC BLOCK SIGNALS

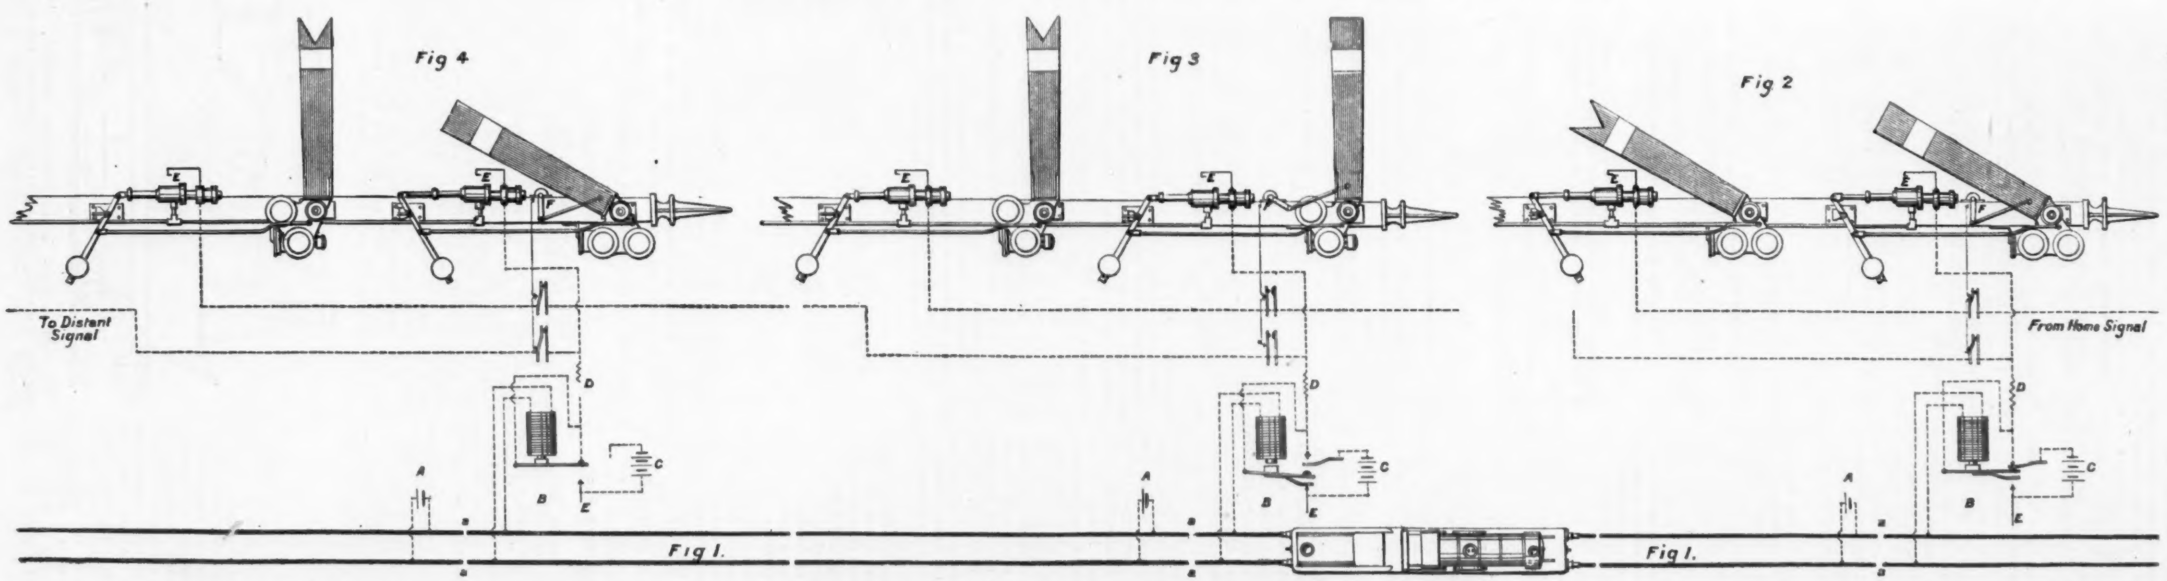

Fig 4 Fig 3 Fig 2 Fig 1. Fig 1.

ELECTRO-PNEUMATIC AUTOMATIC BLOCK SIGNALLING.

In February, 1894, Mr. George Westinghouse, jun., wrote a letter to Mr. W. F. Allen, the Secretary of the American Railroad Association of New York, on the subject of electro-pneumatic automatic signalling. In view of the great extension of this system in the United States, and of the attempt now being made to introduce it on this side of the Atlantic, we cannot but think it opportune to reproduce the greater part of this letter—slightly altered to suit English practice—as follows:—

It is now universally conceded that no single subject demands more urgent consideration than the adoption of proper signals for the safe running of railway trains. From the beginning of the operation of railways, the necessity for two all-important safeguards was at once apparent—(1) A proper system of signals for warning the engine-driver of danger ahead, and (2) apparatus to enable the engine-driver to stop his train in the shortest possible distance. The solution of the latter problem, the stopping of trains in the shortest possible distance, it may safely be said, has reached a point where further possible improvement, so far as results in quick stopping are concerned, will be unimportant so long as the friction between wheels and rails is the limit of retardation.

Proper signals to warn the engine-driver of danger ahead means a system of signals which shall indicate the exact condition of every foot of the line, and shall comply with the following general requirements:—(1) When the line is clear, and there is no danger, the signals shall be so displayed, and in such an unmistakeable manner, that an engine-driver will have no doubt of his right to run ahead at the high speed now demanded. (2) If the line is obstructed, a warning signal shall be automatically displayed, advising the engine-driver that at a distance ahead he will find a signal at danger beyond which he must not pass. (3) The signal system shall be so organised that the opening of a pair of points, the removal or breaking of a rail, or the fouling of the main line by a car on a siding, shall automatically cause warning and danger signals to be displayed. (4) In the event of any accident to the signal apparatus, the signals must automatically assume a position indicating caution or danger.

In signal installations with block signals moved by hand power, it has been necessary and customary to have signals normally at danger, thus requiring an effort of the operator to move a signal to safety on notice of the approach of a train, and, on some lines, block signals have been so arranged as to remain at danger from their counterweights, unless held in the safety position. Instances where these signals have been fastened by the operators in the safety position when there was actual danger, and where they have cleared the signals when they should not have done so, have been sufficiently numerous to show that this method of working does not meet the requirements. It has been suggested that all of the automatic block signals should be normally at danger, and only cleared in front of a train, if the track ahead be clear. Such an arrangement of automatic signals in blocks of from one-fourth to one-half mile apart would be very disadvantageous, for the reason that engine-drivers would be constantly under the impression that there was danger and thus be unable to run with confidence. Again, gangers, inspectors, and others would be unable to tell whether the system was in operative condition or not, as is so readily the case where the signals are normally held at safety only when every essential part is in working condition.

From the beginning of the introduction of disc signals operated by the well-known and well understood electric track circuit system, there seems to be a natural prejudice against the disc or banner form; and therefore, in perfecting a comprehensive system of signalling apparatus, the first question to be determined was the character or form of signal to be employed. It took but little time to disclose the fact that long experience had practically led to the general adoption of a semaphore signal, the position and indication of which is determined by the eye at a greater distance than any of the other forms of signals which have been used, while the question of colour is eliminated for at least one-half of the twenty-four hours. A semaphore signal the form and shape of which has been evolved by long experience, is of considerable weight, is always exposed to atmospherical conditions, because the view of its positions must be unobstructed, and is, or should be, so counterweighted that it will assume its danger position in the event of a break in any of its connections. The power required to move such a signal with certainty to its various positions is considerable, and it was found to be greatly beyond the capacity of ordinary electric batteries, though such batteries have furnished an adequate power for the tripping of devices for the utilisation of weights arranged to turn disc signals.

The long and successful use of compressed air naturally suggested its employment as the motive force for the movement of the signals, a supply being obtainable along the whole line through a main pipe fed by pumps located from ten to twenty miles apart, at convenient stations where steam power already exists, and which would furnish compressed air for any number of signals, and also provide the power necessary to move switches. Experience had fully demonstrated that compressed air could furnish an adequate power, and that electricity could be used to bring that power into operation for the movement of both switches and signals, and that, by the utilisation of the rail circuit, and the proper arrangement of signals, a thoroughly safe and practicable system could be applied to railways, meeting the foregoing general requirements, and which would be automatic in operation and safer than any system of signals dependent upon men for their movement.

The automatic pneumatic system of block signals.—With the foregoing general remarks, I will now describe the automatic pneumatic system of block signals, first applied to the Pennsylvania Railroad between East Liberty and Wilkinsburg in 1884, extended to Pittsburgh in 1889, and from Wilkinsburg to Stewart Station in 1892, covering a distance of sixteen miles. All of these signals have been in constant daily use, and the very first ones erected are in use without any alteration except an improved relay in connection with the track circuit. The track of each of the main lines is divided into electric circuits varying in length from one-quarter to one-half a mile. About 50ft. to the rear of each section is a post carrying two semaphore signal blades. The upper one, according to the general practice of to-day, is the danger or "home" signal, painted red, and governing the section immediately ahead, and the lower is the distant signal, painted green, and working in harmony with the danger signal of the next section. Each semaphore is operated by a cylinder 3in. in diameter, fitted with a piston, the rod of which is connected so as to move the signal to its clear position when air pressure from the main line is applied to the piston, that being the normal position of all signals when the track is clear for the movement of trains.

The accompanying drawing fully illustrates the foregoing. The original drawing showed the signal posts on the other side of the line, according to American practice. The drawing here appended has been modified, so as to correspond withEnglish practice. Fig. 1 represents two electric sections of track, and portions of two others. At the points *a* are fish-plates made of wood, to electrically separate the rails of one section from those of the adjoining. At A is what is called the "Track Battery," having one of its poles connected to one line of rails, and the other to the opposite line of rails. At B are electric instruments called "Relays," or devices used for switching the current from a more powerful battery C for the operation of the valve mechanism of the signal cylinders. These "relays" are electro-magnets having wires connected to the rails, so that when the two lines of rails of an electric section are not joined together by the wheels and axles of a vehicle or otherwise, the current from the battery A will flow through the rails and through the wires of the relay magnet, causing it to attract its armature, so as to connect the battery C with the electro-magnet of the signal cylinder. Fig. 2 represents the top of a signal post with its two blades in the safety position, indicating that the section which it governs, and the one immediately ahead of it, are unoccupied. Fig. 3 represents the signal at danger, caused by the presence of a train, as shown on Fig. 1, which causes the current of the battery A of that section to flow through the wheels and axles of the engine, thereby cutting off the current from the relay magnet of that section. In this manner the circuit from the battery C is interrupted, so as to permit the air in the cylinder operating the danger or upper signal to escape, upon which occurrence it assumes, by the action of its counter-weight, the position shown indicating danger. The movement of this signal arm interrupts the circuit governing the lower signal, which also assumes the horizontal position. The circuit governing this second or cautionary signal is extended to the home signal of the preceding section—Fig. 2—so that when the danger signal on the same post with the cautionary signal assumes the normal or safety position, the cautionary signal still remains in the horizontal position until its home signal—top signal of Fig. 2—is also cleared. Fig. 4 shows the upper or danger signal in its normal or safety position, and its lower or cautionary signal in its horizontal position, acting as a cautionary or "tell-tale" signal to the home or danger signal of Fig. 3.

When the train reaches the next section to the right, it causes both signals of Fig. 2 to assume the danger position, while those at Fig. 3 remain at danger until the last car of the train passes from that section, whereupon the upper or danger signal resumes its safety position, still leaving the other signal to indicate the condition of the signals in Fig. 2. A section through the signal cylinder, its magnet and valves, is annexed. Air pressure from the main pipe enters through the connection A and passes through passage T to the interior cavity C. This cavity contains a valve S P held closed by a spiral spring, and the spindle of this valve is prolonged upward and inserted in the spindle F of the armature B. The lower part of this spindle F is formed into a conical seat to act as an exhaust valve. As soon as a current coming from the relay battery passes through the coil of the electro-magnet M, the armature B is attracted and brought down. The spindle F then closes the exhaust passage and pushes the spindle S P off its seat, so as to admit compressed air through the passage E to the space above the main piston P. This piston is thereby lowered, putting the signal to "clear."

When the electric circuit is again interrupted, the armature B is released and pushed upwards by the spiral spring surrounding the spindle valve S P; the admission of air to the cylinder S C is thereby cut off and the exhaust passage opened, thus allowing the air above the piston P to escape through H, and the piston is then raised by the action of a counterweight, putting the signal to "danger." Each signal blade carries an appropriately coloured lens, which covers a light when the blade is in the horizontal position, showing red for the upper signal and green for the lower signal, and exposing the white light for both signals when they are in the position to indicate that the track is clear. An air pressure of about 60 lb. is maintained in the pipe along the track, and the batteries are placed in wells located near the signals.

From the preceding description it will be seen that so long as the two lines of rails forming the track of a section are joined electrically by the wheels and axles of a vehicle or otherwise, the appropriate signals will remain at danger to guard such section. Where points are included in the line, a switch box is arranged in connection with each pair of points in such a manner that its movement will cause the proper signals to indicate danger, and enough of the track of each siding is included within the track circuit to ensure the display of danger signals in case a car on such siding fouls the main line. It will also be seen that the removal or breaking of a rail will interrupt the track circuit and thus set the proper signals to danger. A rupture of the air pipe will permit the air to escape from all of the cylinders, and thererby set all signals to danger; and the failure of the battery of either the track or signal magnet will cause the air to escape from the signal cylinder, and thus set the corresponding signal to danger. There has been perfected and used to a limited extent an arrangement whereby the points of any section may be automatically locked in such a manner that they cannot be moved after a train has once passed the signals governing such section, and until the train has passed into the next section. It will be seen that, as arranged on the Pennsylvania Railway, each danger signal has a warning signal the length of a section from it. When running at sixty miles an hour or more, the distance required within which to stop a train is often greater than would be available if the danger signal had not a cautionary signal to notify the engine-driver of its position. The system as described shows that the cautionary signals are from one-quarter to one-half mile distant from the danger signals, so that the engine-driver receives timely warning to stop.

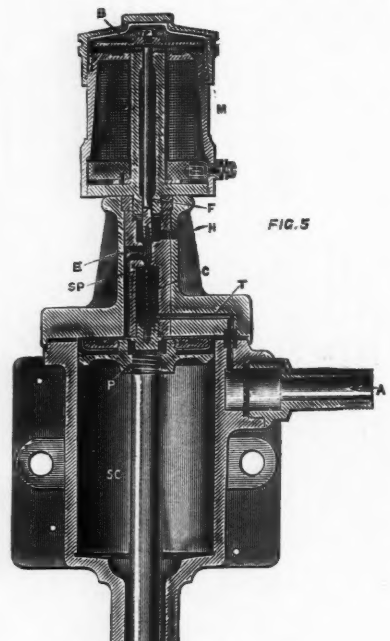

FIG. 5

While it is possible that some of the details of the apparatus described may be still further modified and improved—in fact, some alterations of the valve of the signal cylinders, and in the relay magnets, have already been made, and are now being introduced as substitutes for the earlier mechanism—the fact remains that the principles involved in this system described are the true ones, and the mechanism will be found, with proper care, to be reliable and efficient under all conditions. It should be borne in mind that this system has been devised to take the place of what is generally known as the "block system," requiring signal boxes wherein operators, guided by proper telegraphic instructions, display appropriate signals to govern the movements of trains. It has been found, especially in England, where the block system was first developed, and its use enforced by the Government, and where the traffic is very heavy, that these cabins, to afford absolute safety, require to be located so close together that the cost of operation and maintenance is a serious burden. Frequent failures of the operators to display the proper signals, or to correctly interpret the communications from the different cabins, led to the development and use of systems which are exemplified by that known as the "Sykes," wherein such operators are required to co-operate before either one may give a clear signal for an approaching train. It would seem at first that such a system would be an absolute safeguard, but it has been found necessary, under certain circumstances, where these stations are a considerable distance apart, to give, under general rules, engine-drivers written orders to proceed with caution past a danger signal until a clear signal at the next cabin should indicate a right to proceed at full speed. A serious defect in this system has been shown by instances wherein engine-drivers, after receiving orders to proceed with caution past danger signals, have been deceived by finding the next signal clear—owing to the operator being asleep—while the block was still occupied by a train which had been permitted to pass, a condition which may repeat itself at a critical time so long as an operator has the power to permit his signal to remain at the clear position when the track ahead is occupied or obstructed in any manner.

In all block systems requiring operators, the first cost where the blocks are located at the telegraphic stations is moderate; but when the time arrives that such cabins must be within one mile of each other, the cost of operation and maintenance becomes so great as to place such a system out of consideration. On the twenty-five miles of the Pennsylvania Railroad between Jersey City and Amboy Junction, equipped last year with the automatic pneumatic system of block signals, twenty-three signal cabins have been discontinued, dispensing with the services of forty-six men. The pneumatic signals require for their care and maintenance ten men, leaving a large margin for the employment of competent men to maintain the automatic system in the most perfect condition.

By placing the pneumatic blocks from one-fourth to one-half mile apart, the capacity of a railroad is sufficiently increased, as compared with the ordinary cabin block system, to fully cover the first cost of such signals. The rules adopted governing the use of these signals require an engine-driver to stop his train in obedience to a danger signal. He is, however, permitted to proceed with caution after a delay of one minute, until his movements can be governed by the next signal. It frequently happens that the engine-driver of a train can observe the position of the semaphore signal of the next two or three sections, and thus the movement of trains is greatly facilitated with absolute signal protection.

JOHANNESBURG ENGINES.

On page 12 we illustrate one of the four large pumping engines recently constructed for the Johannesburg Waterworks Company by Messrs. James Simpson and Co., of Pimlico. These engines are triple-expansion Worthington pumping engines, each capable of easily delivering 1,000,000 gallons per twenty-four hours against a head of 450ft. They are to work with a steam pressure of 150 lb. per square inch, and the high-pressure cylinders are fitted with cut-off valves having expansion plates adjustable by hand whilst working. The sizes of the cylinders are 8½in. high pressure, 13in. intermediate pressure, and 21½in. low pressure, with a stroke of 18in. Each engine exhausts into a jet condenser, below which the air pumps are placed directly in line below the low-pressure cylinders. The main pumps are a feature in the design, being extremely compact and specially designed with a view to transport. They are fitted with small Worthington valves, which can be easily examined from manholes on the castings. The plungers are of cast iron working in gun-metal bushes. The piston and pump rods are steel, and the air pump rods delta metal. All the bushes are case-hardened steel, and all working pins are also case-hardened. No air vessel beyond that shown on our illustration is required, owing to the extremely uniform flow of water which is obtained from these pumps, where one side commences to take up the load as the other side comes to rest.

The foundations required are very light, and it is a great advantage not to have any of the machinery below the floor level, but all in full view. The cylinders are all covered with mahogany lagging, and with the copper pipes, and the other bright parts, the engines present a fine appearance, and do the builders great credit. It may be of interest to our readers to know that these four engines were built entirely from the raw material in the short period of eleven weeks, the first engine being complete in five weeks, the second in seven, and the third and fourth with a fortnight intervening. Messrs. Simpson and Co. have now made over 200 Worthington engines for every service conceivable, including sewage, water, main drainage, and irrigation, and it is a proof of the completeness of the equipment of their factory that these engines were built ready for shipment in so short a space of time.

ALMANACKS AND CALENDARS FOR 1896.

Messrs. E. R. and F. Turner, of Ipswich, and 82, Mark-lane, have sent a handsomely got-up day-to-day tear-off calendar, carried on a tastefully arranged background, upon which is printed an almanack for the whole year. Six of Messrs. Turner's specialities relating to flour milling are illustrated upon the background by nicely executed drawings, and on the back of the large card is a selection of postal and other information and calendar for 1897.

The Hunslet Engine Company, Leeds, send a nicely-executed monthly tear-off calendar, the background of which carries small but beautifully clear photographic representations of five of the contractors' and other locomotives made by the company.

Calvert's Mechanics' Almanack and Workshop Companion, which is sold for 4d., has, as usual, sixty-four pages of well-selected contents, including the almanack of dates and events.

The Quickest Telegram on Record.—An article of exceptional interest, entitled "The Telegraph Systems of the World," appears in the *Windsor Magazine* for January. As an example of "what can be done in the way of transmission when the wires are free and the operators waiting," the writer says:—"Some years ago, at a telegraphic *soirée* in the Albert Hall, a feature of the evening's amusement was the sending of a message to Teheran, in Persia, and back. A sending and receiving instrument had been put up in the hall and connected with the wires of the Indo-European Telegraph Company. This line crossed the Channel by cable to Germany, and then by land lines ran over Germany, South Russia, Caucasus, Armenia, and Persia, to Teheran. At Teheran the wire was joined to a second line of the company, returning to London by the same route. The lines were cleared for the experiment, and, at a given signal, the key of the sender was pressed by the Prince of Wales. The instant that the button of the instrument was touched, click went the receiver. The current had been to Persia and back!"

LETTERS TO THE EDITOR.

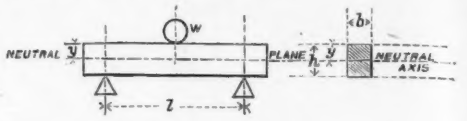
(*We do not hold ourselves responsible for the opinions of our correspondents.*)

TRANSVERSE LOADS ON BEAMS OF MILD STEEL.

Sir,—In reply to the letter, dated 18th inst., of your correspondent "Transverse," I trust the following will be of service to him:—

Rankine tells us "the transverse strength of a beam may be found by equating the greatest moment of flexure expressed in terms of load and length to the moment of resistance of the cross section where that moment of flexure acts." "Transverse" desires transverse strength of a 1in. by 1in. section on 12in. bearings.

Take wrought iron for comparison with the authorities quoted by "Transverse"—



Moment of flexure $= M_o = \frac{W\,l}{4}$ for central load. Moment of resistance to bending $= M_R = \frac{f\,I}{y}$. f = modulus of rupture. I = moment of inertia. y = distance of neutral plane or axis from the plane in which the stress acts.

The value of y is to the cross section, in proportion to its depth, viz., $\frac{y}{h}$. Therefore M_R for bending, and considering the depth of section $= \frac{f\,I\,h}{y}$.

The values of I for similar sections are related as their breadths and the cubes of their depths, viz., $b\,h^3$; therefore I for cross section $= \frac{I}{b\,h^3}$.

The moment of transverse resistance of the cross section becomes $\frac{f\,I\,h}{b\,h^3\,y}$, and as the value of $I = \frac{b\,h^3}{12}$

$$M_R = \frac{f\,b\,h^3\,h}{12\,b\,h^3\,y}.$$

$\frac{y}{h}$ for rectangular sections is always $\frac{1}{2}$; therefore $M_R = \frac{f\,b\,h^3\,2}{12\,b\,h^3}$.

The resistance of flexure, *i.e.*, the lateral adhesion of fibres, is related to similar cross sections as their breadths and the squares of their depths.

Thus we have the moment of resistance of the cross section $= M_R = \frac{f\,b\,h^3\,2\,b\,h^2}{12\,b\,h^3} = \frac{f\,b\,h^2}{6}$.

To equate M_o with M_R we have $\frac{W\,l}{4} = \frac{f\,b\,h^2}{6}$, and $W = \frac{f\,b\,h^2 \times 4}{6 \times l}$.

Rankine gives modulus of rupture for wrought iron as 42,000 lb.; so, to consider the inch square section 12in. long, we have $W = \frac{42{,}000 \times 1 \times 1^2 \times 4}{6 \times 12} = 2333\cdot\dot{3}$ lb. $= 1\cdot0416$ tons ultimate strength.

This exactly coincides with one of the authorities quoted by "Transverse," and I think that when your correspondent uses the same value for modulus of rupture in each of the formula he quotes, he will find them agree pretty accurately. For instance, Molesworth gives $\frac{4\,K\,B\,D^2}{L}$, in which K = 68 cwt. is the coefficient of rupture, not the modulus. Compare this formula with the working I have given, and they will be found to be the same, excepting that Molesworth has evidently divided the modulus by the 6, and gives a coefficient.

68 cwt. × 6 = 45,696 lb. modulus of rupture, as against 42,000 used by Rankine.

If "Transverse" inserts correct value of f or K for any material with which he wishes to work, he should find no further difficulty.

"Transverse" also asks for explanation of Molesworth giving E = 10,000 for cast iron in "Beam Deflection":—

	E in lbs.	Ult. tens. strength in lbs.
Molesworth (beam deflection)	22,400,000 ..	—
,, page 23	18,400,000 ..	—
Humber	18,000,000 ..	16,000
Anglin, average	14,100,000 ..	15,332
Rankine, minimum	14,000,000 ..	13,400
,, average	17,000,000 ..	16,500
,, maximum	22,900,000 ..	29,000
Seddon, minimum	12,000,000 ..	11,200
,, average	17,000,000 ..	20,160
,, maximum	23,000,000 ..	33,600

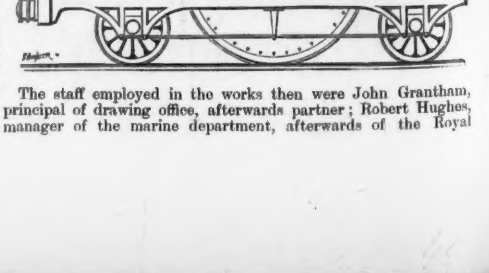
I think from these figures that Molesworth probably took a figure so high on the assumption that only such cast iron as would stand a high tensional stress should be used for beams. This, however, should not trouble "Transverse," as he may readily arrange E to suit such tests as he may specify.

Kendrick Edwards.

157, Onslow Drive, Dennistoun, Glasgow, Dec. 23rd.

EARLY LOCOMOTIVES.

Sir,—I send you a drawing of the 10ft. wheel locomotive designed by John Grantham, draughtsman at Mather and Dixon's North Foundry, Liverpool. They were marine engineers, which may account for the outside view resembling a steamer; the driving wheel splashers like a paddle-box, and the handrail plates brought to the buffer planks shaped like the stem of a vessel and intended to take the wind pressure off the front end of the engine. The great diameter of the driving wheel shows that Brunel had something to say about it, perhaps ordered it to be made twice the size of any other then made; everything with him must be greater than ever done before as the Great Western Railway, the Great Western Steamship, the Great Britain the first iron and first screw steamer; and lastly, the Great Eastern, both screw and paddle steamer, which he did not live to see under steam.



The staff employed in the works then were John Grantham, principal of drawing office, afterwards partner; Robert Hughes, manager of the marine department, afterwards of the Royal

Arsenal, Woolwich, and inspector of steamships; Mr. Banks, locomotive foreman, well known at Derby, on the Midland Railway; Mr. Buddicomb, first locomotive superintendent of the Grand Junction Railway, and of the Locomotive Works at Rouen, France; Josiah Kearsley, first locomotive superintendent of the Midland Counties; George Harrison, first locomotive superintendent Scottish Central, and manager at Brassey's, Birkenhead; Mr. Potts, afterwards of the firm of Jones and Potts, Newton-in-the-Willows, locomotive builders, where the first solid locomotive wheel was made by the wheelsmith Frost.

All the above-named were apprentices and journeymen with me in my time. William Tait, of the firm of Tait and Mirlees, Scotland-street, Glasgow, was the erector of the 10ft. wheel locomotive. I worked mate with him on the same engine. Tait was manager of Neilson's Hyde Park Locomotive Works, Glasgow, in 1845, and his mate—John Wilson—was manager from 1864 to 1884 under Mr. James Reid, sole owner of Neilson's Works. James Smith scarf welded the 10ft. tires. The crank axles were forged at the Mersey Forge when Mr. Norris was manager, and turned by Charles Ackers. Ned Bursing turned the rims and tires on a large lathe, driven by the gearing of the boring mill. I remember having worked on the same lathe, that they had to cut a curved piece out of the shop wall for clearance.

As to the question, "Was the 10ft. locomotive ever built?" in the discussion on the construction of locomotives in the "Transactions" of the Institute of Civil Engineers for 1849, volume viii., Robert Stephenson said he did not attach much importance to the size of the wheels. The 10ft. wheel had been abandoned on account of the difficulty in getting up the speed of trains at starting. Mr. Henry Maudslay observed that nothing had been said as to the proportionate length of stroke. He wished to ask whether, instead of decreasing the diameter of the wheels, a proportionate length of stroke had been given, a great advantage at starting would have been obtained. Mr. R. Stephenson thought that Mr. Maudslay had started an interesting point. The proportionate length of stroke to the capacity of cylinders had not, he believed, been yet correctly ascertained.

The following twelve individuals, I find, bear testimony that two or more locomotives with 10ft. driving wheels were built:—Brunel, Stephenson, Snowball, Maudslay, Gooch, Sturrock, Dean, Wood, Sheward, Bucknell, Wyatt, Crampton. If I was to tell them that the 100 miles an hour Grasshopper, with sandwich frames, was the last 10ft. wheel locomotive, I should be contradicted, as Mr Greenly said. The Cornwall beat that speed on her trial trip down Madeley Bank; we got 120 miles the hour out of her with 8ft. 6in. wheels.

Book makers are apt to make mistakes like myself. Mr. Stretton has much to say on the subject; perhaps he will not thank me for correcting him. In answer to his letter of October 16th, about Mather, Dixon, and Co. re-lining engines and the actual design of them, and about the blue print of the disc wheel, there was no Bath-street Foundry in 1838. John Jones left Bath-street to be manager at the Old Swan Foundry, near Liverpool, in 1835, and never was manager at Mather, Dixon and Grantham, North Foundry, but joined Mr. Potts in partnership at Newton-in-the-Willows about 1839.

I was at the opening of the Liverpool and Manchester Railway, in 1830, as a boy. I was bound apprentice to Mather and Dixon for seven years, James Aspinal, afterwards Mayor of Liverpool, signing my indenture, and I remained with them until 1842, when the works closed, and all the locomotives were built in my time. I put up the first vice in Crewe Works, 1843, built several engines at Crewe, Edge Hill, and Nine Elms; was manager of Salford Rolling Mills, 1854, and rolled the first steel tire ever rolled, Krupp men standing by while I worked the mill. For nine years I was foreman erector for Sharp, Stewart, and Co., when I put the first injector on an engine on the St. Helens Railway; Mr. Robinson was with me, of Sharp, Stewart, and Co. I was manager twenty years to Neilson and Co., Hyde Park Locomotive Works; twenty-five years member of the Association of Engineers and Shipbuilders, and forty years member of the Manchester Association of Engineers.

165, Onslow Drive, Dennistoun, Glasgow, JOHN WILSON.
December 23rd, 1895.

ELECTRIC LIGHT ENGINES.

SIR,—It seems to me that the elaborate and interesting description of the great installation at Deptford, published in THE ENGINEER for the 20th ult., affords room for a discussion on the pressing and important question, What is the best type of engine for driving dynamos?

To begin with, I think we need not complicate matters by considering the smaller types of engine. I have carefully watched the progress of electric lighting, and I have no doubt at all that the small manufacturer of current cannot in the future compete with the great establishments. Electricity is a commercial commodity now-a-days, not a scientific toy. It must be made and sold at a profit, and this can be best done on the large scale, like cotton cloth, or locomotives, or ships. Thus, for example, the standing charges will be practically the same for an output of 500, 750, and 1000 units. The larger output will demand more coal, and more interest and depreciation. That is all. Under these circumstances, I think we may regard 500-horse power as the smallest engine worth considering, and 2000-horse power as the largest that it will be convenient to use. Now these figures include just that class of marine engine most frequently used. The engines indicating 500-horse power to 1000-horse power in cargo steamers may be counted by the thousand. I do not hesitate to say that for every land engine or mill engine of over 500-horse power made in this country, twenty marine engines are turned out, and it is this that has placed Scotch, English, and Irish marine engines in the very front rank of mechanical engineering. An enormous experience concerning them is available. The marine engine has to run for days and even weeks at a time without being stopped for a moment, and it undergoes most severe trials of endurance in a gale. In order that it may discharge its duties, many special features, apparently very trifling, really very important, are adopted. The marine engineer knows what is wanted. The stationary engine builder does not, simply because, first, he has not the experience; and secondly, because no one wants mill engines to run day and night for weeks. All these things point to the conclusion that the marine engine is the best for driving dynamos, and that the proper man to build such an engine is one accustomed to that class of work. I do not wish to belittle the Corliss or any other type of mill engine, but that does not prevent me from saying that the marine engine is *the* type.

Take now the engine designed by Mr. d'Alton for driving the 1000-unit Ferranti. Here we have a type of compound marine engine which is very similar to those designed by Mr. Humphries for the great Atlantic steamer City of Rome—namely, three independent compound engines driving a triple crank shaft. The cylinder proportions are different and the details different. Much the same type was used for years by Mr. W. Allan, of Sunderland, the major difference being in the condensing arrangement.

It is no joke to run an engine indicating 1500-horse power at 156 revolutions per minute. That speed puts Corliss gear out of the field at once. I very much doubt if any builder of land engines has yet produced an engine of 1500-horse power which runs at nearly that speed. I may be mistaken on this point, but I think not. All the great firms, such as Musgrave, Hicks Hargreaves, &c., use Corliss gear, or, at all events, some form of trip gear, and that pins them down to about 90 revolutions per minute as a maximum. But 156 revolutions is quite common with such marine engine builders as Humphreys and Tennant, Maudslay, Sons, and Field, Hawthorn, Leslie, and Co., and, indeed, any firm building engines for warships. The land engine builders can know nothing by experience about these high speeds, which can only be maintained with success by the aid of very special methods of construction, which, of course, are not given broadcast to the world. It remains, of course, to be seen whether Messrs. Plenty have had all the knowledge needed. But it is very much in their favour that they have already built marine engines, and I believe I am right in saying that Mr. d'Alton has himself had a large experience. So we may take it for granted that the Deptford engine will be all right.

I am very pleased to see that you, Sir, have done justice to the marine engine and the marine engine builder in what you have already said, and all that you have said I fully endorse. So much concerning the type of engine most likely to run without giving trouble. It remains to be considered that the marine engine always runs with a constant load, and the electric light engine does not, and herein lies a difference that may be puzzling and troublesome. As all trip gear is excluded by the speed, how are we going to regulate? Now, from a somewhat extended experience with electric light engines of considerable power, I have come to the conclusion that governing can best be done by the throttle valve, the cut-off being regulated by hand. Thus, for example, the small cylinder may have Meyer's slide valves, which admit of being partially relieved of pressure; a good governor will do the rest. In order that my view may be taken at its proper value, I must explain what is constantly overlooked. The load on an engine driving a dynamo scarcely varies at all for long periods. An engine starts, we shall say, at 500-horse power; it will be run for a couple of hours at that, then the load goes up to 750-horse power in the course of a few minutes; then there is steadiness for a while, and then it runs up again by a jerk. The power diagram of an engine will be somewhat like this, and for this the hand adjustment of the cut-off answers quite well. The throttle valve will have little or nothing to do between whiles, if the steam pressure is kept steady. The little diagram I have sketched must not be confounded with the station diagram, which is very different, because several engines are used, and as each is loaded to its full capacity another is started.

I know that several discussions have taken place as to the relative merits of cut-off and throttle-valve regulation, but to my mind they have all turned on a question of the most secondary importance—namely, which best saves coal. But in a great electric light factory, the first point, and the middle point, and the last point is that the current shall be supplied steadily without interruption. If this can be done year in and year out with a saving of coal well and good, but no saving will compensate for bad current, the smallest interruption of current, or any fluctuation in pressure or quantity.

To sum up, I repeat that the marine engine is the exemplar for electric light engines, and that throttle-valve governing, properly done, will, in the long run, prove more satisfactory *to those whose houses are lighted* than will any other system.

Glasgow, December 30th, 1895. D. U. M. BARTON.

SIR,—In spite of the many interesting remarks made in your last issue upon the new 1000-unit machine at Deptford, to an impartial reader many of the generalisations therein contained appear both hasty and inaccurate. It would be interesting to know exactly what meaning you can attach to the phrase "marine type of engine," unless it chances that it is your intention to include any vertical inverted engine working on more than one crank in that category. It is hardly a work of such insuperable difficulty to construct a three-crank vertical engine that we need resort to marine engineers to ensure its fitting construction, whilst the special points that do require minute attention, viz., fly-wheel and governor regularity, are just those in which marine engine makers can have acquired little or no experience. It is therefore somewhat surprising to find a statement of this nature in a paper with a reputation to maintain. It would be hard to find in modern, well equipped electric light stations one engine in twenty that has been turned out by a firm devoting themselves exclusively to marine work.

Similarly it is significant that even on board ship the many electric light engines in use are in the great majority of cases turned out by firms who do not undertake general marine work, but who devote themselves to high-speed or other engines. In view of these facts, your statement that engineers must resort to the marine engine builder for a successful electric light engine, seems to have neither substance nor shadow behind it. It is not so in fact, and were our practice reconsidered there is nothing to show that an alteration in that direction would ensue; and in spite of the ungenerous and unwarranted slur upon our stationary engine makers, it will be found that the electrical engineers of to-day are too wide-awake to leave the manufacture of their engines to the tender mercies of the marine engine maker. With regard to the engine anent which these unfortunate remarks occur, the designers have evidently carefully considered one point, steadiness of running; it would appear that this has been done at the expense of many others, and to many it will appear entirely questionable whether six cylinders, and the consequent increase of expense, frictional loss, and liability to break down, are in any way necessary to ensure those results so highly lauded in your article of the 20th inst.

The arrangement adopted is doubtless extremely efficient for securing an even turning moment. It must be remembered, however, that the large weight of the reciprocating parts in a high-speed tandem engine having short connecting-rods introduces large irregularities and reversals of the effective piston thrust due to inertia. These would have been absent or decreased had the single cylinders replaced the tandem arrangements. On the whole, therefore, it is extremely doubtful if the engine described will give a more uniform turning moment at reduced loads than would a good triple-expansion engine fitted with an arrangement by which the governor controlled the steam admission—and thereby the work done—in each cylinder; whilst such an arrangement would dispense with three cylinders and three valves, and have considerably added to the stability of the combination.

With regard to the shortness of the connecting-rod, an evident oversight has been made in describing the ratio to the crank. The proper ratio should be about $4\frac{3}{4}$ times the crank. With regard to the regularity of rotation at reduced loads, it must be remembered that if the load fell from 1500 indicated horse-power to 500 indicated horse-power, the energy fluctuation, rising from, say, 5 per cent. to 12½ per cent. at the same time, then, although the apparent irregularity of rotative effort rises to 2½ times its original amount, yet the fly-wheel irregularity has not been increased. This is due to the fact that any irregularity of angular velocity corresponds to a given addition or subtraction of a definite amount of energy of the wheel. A greater percentage of irregularity at a lower power does not actually in all cases correspond with a rise in total energy gained or lost by the wheel during a period. In fact, in any such engine, since the steadiness must be sufficient to ensure regularity at the heaviest loads, provided that the coefficient of fluctuation of energy does not rise faster than in inverse proportion to the load, the angular variations do not become larger at the lighter loads. ROBERT A. BRUCE.

6, Cyprus-street, Bolton, December 24th.

[We publish our correspondent's letter because it raises questions worth discussing. The Deptford engines are essentially of the marine type. On this point no builder of marine engines can have the smallest doubt. The three distinct engines were only adopted after mature consideration of the conditions to be fulfilled, and as a result of extended experience with various types of engine. If Mr. Bruce will turn to page 608 once more, he will see that we have said nothing that can be taken as a slur on engine builders. We have said, first, that our marine engineering is the best in the world. Can Mr. Bruce dispute this? Secondly, that many of our stationary engine builders must be classed below some of the continental builders. Is not this true? Where is the British marine engine builder that can be classed below the foreign marine engine builder? The interest of Mr. Bruce's letter centres, however, in the discussion of the means of producing regularity of turning under extreme variations of load, a point on which very wide differences of opinion exist.—ED. E.]

ASSOCIATION OF WATERWORKS ENGINEERS.

SIR,—The response I have had to the publication of my letter of the 16th November last in the professional journals on the above subject has been so satisfactory that I am encouraged to take further steps to bring the scheme to a successful conclusion. I have therefore much pleasure in announcing that a meeting will be held in the Exchange Hall, Smithy-row, Nottingham, by the kind permission of the Mayor, on the 11th January, 1896, at one p.m. (1) to discuss generally the subject of forming a Waterworks Engineers' Association for Great Britain; (2) to elect a provisional president, secretary, and committee, with powers to draw up rules and bye-laws, and to take such other steps as they may think desirable to establish the Association upon a sound basis; (3) general business; (4) to receive a paper on the Cologne Waterworks, by Mr. C. H. W. Biggs.

D. M. F. GASKIN, M. Inst. C.E.

Municipal Offices, Nottingham,
December 27th.

AN OLD BAND SAW.

SIR,—I am extremely pleased to find your notice of the band saw machine in the Thames Ironworks sawmills. I may tell you it is now more than twenty years since it was fixed. The first one I designed for Messrs. Samuda Bros., Poplar. I took the order for that, also the one at the Thames Ironworks. I only had a little piece of wood ¼in. scale as model of the worst piece of backing—teak—which had to be cut. I saw the first piece cut, and the machine made the cut as perfectly as though it had been at work for months; the timber being lined on both faces. The mill foreman started the saw into the cut on one side, and a mere lad guided the saw out on his side. I begged the first slab, which was about 26ft. long; the cut was made in about ten minutes. It could have been made in less time had the workmen known the machine. Before the first machine—Messrs. Samuda Bros'.—was made, a good saw-mill machinist, one of the first of the day, said it might be put on the scrap heap at once, it would not answer.

London, December 18th, 1895. J. HAMILTON.

SELF-PROPELLED ROAD CARRIAGES.

SIR,—Whence all this bother about a name for these? When one sends for a carriage at present one does not say, "Bring the 'horse brougham' or the 'horse dog-cart,'" nor does one generally remark, "I'm going into town on the 'cable drawn tramcar.'" Let the coming carriages be simply called "carriages," and if necessary for definition at any time let us call them "traction carriages," following the analogy of traction engine. But above all things let us not render life more hideous in word as well as deed by coining such hybrid sounds—I cannot call them words—as "autocar," "motocar," nor travel in the future in, as it were, a negative, such as a "nonequine." W. T. F.

Forfar, N.B., December 30th, 1895.

STOREY'S DEAD WEIGHT SAFETY VALVE.

SIR,—In your article appearing on page 646 of your issue of December 27th on the above subject, you ascribe to Mr. Lavington E. Fletcher the design of both the arrangements of dead weight safety valves for kitchen boilers, whereas the patent enclosed safety valve has been designed and patented on behalf of the National Boiler and General Insurance Company, Limited, Manchester, with the object of overcoming the difficulty of efficiently protecting the simple form of valve from damage and clogging by soot when fixed directly on the boilers in the flues. We shall be much obliged if you will kindly insert this in your next issue.

ISAAC STOREY AND SONS.

BULL'S METAL LAUNCH.

SIR,—Referring to your interesting notice of the Bull's metal launch that we built recently for Messrs. Siemens, for use with the cable ship Faraday, we notice one error which, with your kind permission we would like corrected, in the beam of the boat, which is not 3ft. 7in. but 7ft. 3in. Were it not that our Mr. Des Vignes is so celebrated for fast and narrow river launches, we should not ask you to make this correction, but we think that under these circumstances it is just as well to point it out.

G. F. G. DES VIGNES AND CO.

17, Victoria-street, December 30th, 1895.

TRADE AND BUSINESS ANNOUNCEMENTS.—Messrs. Barry and Higham, consulting and constructional engineers, have moved to 15, Great George-street, Westminster, S.W.—Mr. E. H. Birley, of 80, Deansgate, has been appointed agent in Manchester for the products of Messrs. John Spencer and Sons, Ld., Newburn Steel Works, Newcastle-on-Tyne.—Messrs. F. Wiggins and Sons, mica merchants, wish to notify that owing to the great increase of business necessitating additional warehouse room, they have purchased No. 103, Minories, and that during the demolition and rebuilding of that and their old house, No. 102, Minories, they have taken temporary premises at Nos. 62 and 63, Minories—opposite—where for the next twelve months all communications should be addressed, or to their other establishment, 10, Tower Hill, London.—Messrs. Matthew Shaw and Co., 81, Cannon-street, have converted their business into a private limited company.

HOW THE CABLE WAS CARRIED ACROSS AUSTRALIA.—A writer on "The Telegraph Systems of the World," in the January issue of the *Windsor Magazine*, gives the following graphic account of the difficulties involved in carrying a cable across Australia:—"It was the year before the Eastern Extension carried its cable to Hong-Kong that it concluded to go on to Australia, on condition that one, or all of the Colonies combined, would lay a land line across the continent to meet it. This offer was accepted by the South Australian Government. This colony then numbered 170,000 inhabitants; it was in debt heavily for railroads and telegraph lines in the settled parts of its territory, but it bravely set aside the money for the new undertaking. The work was begun early in 1870. All but two or three hundred miles of the two thousand from Adelaide on the south to Port Darwin, the cable terminus on the north, was through a land of either the worst reputation or utterly unknown, save from the reports of the one explorer who, with infinite risk and hardship, had traversed it nearly ten years before. The expedition was to be baffled by nothing, however, They carted every inch of their wire, most of their poles, all of their supplies, across a country often waterless, and so hot that the thermometer burst and the pork melted in the brine. They saw their cattle die of hunger and thirst. They were forced literally to crawl through miles upon miles of scrub of the most exasperating character. The natives harassed them constantly, stealing their supplies, threatening their finished work, and rigging up their insulators as spear-heads, to use when the native boomerangs were not up to the occasion. The northern portion of the work was once abandoned, so hopeless did it seem. Again, terrific floods drove the expedition entirely from the field. In spite of the loss and discouragement, the line was finished in two years and a half."

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

**** In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

**** All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

**** We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

H. B.—*(1) There is no examination. Anyone can write C.E. after his name if he pleases. (2) Write to the Secretary of the Institution of Civil Engineers, 25, Great George-street, Westminster.*

A READER.—*In reply to your question, the following are the dimensions of the cupolas at Derby:—The outside diameters are 5ft. 6in.; inside diameter at centre of tuyeres, 2ft. 10in.; internal diameter at the hearth, 3ft. 4in. There are five tuyeres at the bottom, 3in. square, and three at the top 2in. square, all being arranged to spread the blast over the surface.*

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. £0 14s. 6d.
Yearly (including two double numbers) .. .. £1 9s. 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. £0 18s. 0d.
Yearly .. £1 16s. 0d.
THICK PAPER COPIES—
Half-yearly .. £1 0s. 3d.
Yearly .. £2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

**** The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF JUNIOR ENGINEERS.—Friday, January 10th, at 8 p.m. Paper: "Problems connected with the Working and Testing of Gas Engines and Hot-air Motors," by Professor T. Hudson Beare, Honorary Member.

LIVERPOOL ENGINEERING SOCIETY.—Wednesday, January 8th, at 8 p.m. Paper: "Combustion in Marine Boilers," by Mr. J. R. Fothergill, M. Inst. N.A., M. Inst. Mech. E.

THE ENGINEER.

JANUARY 3, 1896.

1896.

WITH the New Year come hopes, aspirations, resolves—hopes that business will be better, aspirations towards higher professional positions, resolves to avoid mistakes and deserve success even should it not be attained. Are our readers justified in believing that the year just begun will be more prosperous than that which has just passed away? The answer rests on many important considerations. We may be told that as trade is better all round in the aggregate, it ought to be better for the individual. On every side, indeed, we hear the voices of returning industries. Yet such a reply may miss the truth at which it aims. It does not follow that because trade is good on the whole, or bad on the whole, it must also be bad or good for the individual. We have only to keep our eyes open to see exceptions. Let us consider, then, what it is that in the present day—in the closing years of the nineteenth century—makes for success; and to do this we must extend our survey, and, balancing fact against fact, opinion against opinion, consider what is the position of trade in so far as it most nearly concerns engineers, whether civil, engaged in the construction of roads, railways, harbours, canals, or drainage works; or mechanical engineers, doing work too multitudinous in variety to classify or marshal.

The whole world is at war—not the war of armies or fleets, but none the less war. Capital contends against labour, labour against capital; capitalist fights capitalist in trade competition; workman fights against workman in ways which have nothing to do with mere competition. There be men who deplore the facts, who denounce the existence of this warfare, as though nothing good could be said of it; and yet it is far from clear that without it the world would make any progress. Development and civilisation depend for their existence on emulation. The advantages derived from competition are clear to all who think. But even though we admit that trade warfare is an unmitigated evil, it none the less remains for us to take the world as we find it, and consider how we shall go down into the arena and fight with the best chance of success. Turning to labour—to the working man—we find that he has adopted in all its possible fulness the principle of combination. The isolated labourer has small chance at the present day of getting the best treatment he deserves at the hands of his fellow man. In this there is nothing new. The individual has always been weak. History tells us that the authority of the tyrant always depended on a combination of certain individuals who supported the Throne. The people groaned, perhaps, but they achieved nothing until they combined. The great truth that union is strength is fully appreciated; but it is recognised even more clearly that isolation means annihilation. This is the era of combinations, co-operations, unions of all kinds. We see on the one hand, labour combining and fighting to attain its desires—desires which are as often as not apparently sentimental, or irrational and unwise. Thus, for example, strikes are carried on for augmentation of wages, the dead loss of wage incurred being more than could be made up by half-a-dozen years' receipt of the sum in dispute. The capitalist has begun to realise the fact that if he is to hold his own he, too, must combine; and the names of half-a-dozen important federations will suggest themselves to most of our readers. Many political economists will maintain that such combinations of employers are wrong in principle and to be deprecated. Once more the answer is that, right or wrong, they seem to have become indispensable. For ourselves, we believe that more than ever will be heard of them during the coming year; and further that instead of doing injustice to the working man, they may prove his best friend by steadying employment, and preventing the outbreak of petty little wars in districts. Instead of a perpetual, more or less purposeless skirmishing, we shall either have peace or a great war fought out to the bitter end. The very magnitude of such a conflict will be sure to deter the opposing parties from entering upon so tremendous a struggle. Strikes, although we do not believe that they are so disastrous as some persons think, certainly injure the trade of this country; but Great Britain does not stand alone in this respect. The great strike at Carmeaux, for example, seems to show on what uncertain ground the French manufacturer walks. The most destructive and mischievous strikes have occurred in the United States. We venture to think, however, that we shall not only have capital but labour on our side when we say that every great Federation of Employers tends to prevent the occurrence of strikes, and in so far is a commendable thing. But it is not in federation alone that British trade may seek help. We have said that the individual being weak has small chance of attaining success, and this statement admits of a very wide application. The great manufacturing establishments are ruining the small fry. Day by day we find companies carrying on the work done not so long since by individuals. The mutual help of numbers, be it with their purse or their brains, is invaluable. Work can be carried on more cheaply and sold to better advantage by a number of capitalists combined than by one man. A notable example of this is supplied by coal mining. The little pit with an output of fifty to a couple of hundred tons per day cannot live. It is only the great collieries, with pits winding from 1000 to 1200 tons a day, and provided with the newest and most perfect machinery and appliances for sinking, pumping, winding, washing, and screening coal, that can make a profit. Ten individuals, each with £10,000 capital, undertaking to mine and sell coal, each working one colliery, would probably lose every farthing in a year or two; but the ten combined, putting £100,000 into a single colliery, would, with good management, get a fair return for their enterprise. Herein lies in the present day the secret of success. It may all be summed up in one word—combination. But it must not be forgotten that combination carries within itself an element of danger. It is a very simple thing for a number of persons to combine together to attain a given end, but—and herein lies the risk—the combination must have a head. We see private establishments carried on for years with great success. Then in time a change is forced upon its owners, the concern is converted into a limited company, and but too often failure ensues, and this usually because of divided counsels and procrastination. In trade, as in warfare, it happens constantly that a decision must be formed suddenly, or at least with but scant time for thought. When there is one man at the head of affairs there is little difficulty in doing this. If a Board meeting has to be summoned, and the question discussed in all its bearings, hours and days may be wasted when minutes are invaluable. It is in the slowness and unwieldiness of limited companies and syndicates that the isolated manufacturer finds his chance of living; and it will be seen on examination, we think, that the affairs of all the fully successful limited manufacturing companies are guided by one or two masterly and masterful men. How often is it said, and with perfect truth, that the chairman of such and such a company has made it what it is.

But if it be true that combinations of capital are largely dependent for success on those who rule, it is not less true of combinations of workmen. The leaders of the unions have enormous powers for good and evil in their hands. The trade of England during the present year will be prosperous or not as the Union leaders please. This is a startling statement, and it is not true of every year; it is true of the present situation. There is no room to doubt that a very heavy demand will be made in the immediate future for those things which engineers, using the word in its widest sense, produce. Japan and China will need rails, bridges, locomotives, guns, ships, engines. Argentina is certainly better as a market than it has been for years. Africa will make large demands in the early future. In this country there is an enormous accumulation of capital practically idle. If only labour consents to employ that capital and make what the world wants, then trade will not only be good, but excellent. It is true that there are ominous signs, evidences of that delirium which sometimes seizes nations. From the United States come alarms. In Africa something approaching revolution exists, and women and children are being sent out of Johannesburg, that flourishing city called into existence like a palace in the Arabian Nights. In the East we have a situation at once deplorable and next to impossible of prompt settlement. Such conditions are no doubt most unfavourable to trade. They are the antithesis of civilisation, and yet, in the words of a veteran statesman, we may say that nothing but common sense is wanted to determine these quarrels, and give us peace. We believe that in the long run the counsels of common sense will prevail. It is not the interest of any nation to fight; there is no prospect of mutual gain. A European war is always possible, but it is to the last degree improbable. France has her hands full in Madagascar, Italy in Abyssinia, Russia's eyes are set on China; all the fighting that any nation can want is to be had in plenty outside of Europe. All the indications point, war rumours notwithstanding, to a busy year for us. "Almost all branches of the engineering trades are actively engaged," say Messrs. Matheson and Grant, "and subject to the maintenance of peace, the year opens with better prospects than at any time since 1890. The unexpected dispute that has been sprung upon this country by the United States, may retard the general revival, towards which most trades were advancing, but the causes of improvement are too numerous and wide-spread to allow of any long postponement. For while on almost all previous occasions of revival, the recovery has been due to or has coincided with improved demands from America, on this occasion the stimulus comes entirely from our home, Eastern, colonial and foreign markets outside American influence." But it is evident that the Union leaders can spoil everything. If they make demands which masters, with foreign competition before them, must refuse, then the end will be disaster. A strike or two like the Glasgow and Belfast struggle would soon settle the question. To sum up, the time is one of combination. Only the great concerns can work to advantage. The exceptions to the rule—there always are exceptions—are the works conducted by men whose ability, energy, tact, and consummate talent constitute each a host in himself. The prospects of a great demand in the immediate future are excellent; but the demand will not reach Great Britain only, nor will Great Britain be able to fix her own price. That will be settled partly by competitive nations, partly by the leaders of the trade unions. If the latter are reasonable, all will be well; if not—the Deluge.

CIVIL ENGINEERING.

The profession of the civil engineer has during the year 1895 been more interesting in connection with its promises than in the realisation or greatness of its performances. More particularly during the past three or four months the employment barometer in the Westminster business chart has been higher than for some considerable time; and unless political difficulties which are threatening supervene, there are indications of a good deal of work for the civil engineer, mostly, however, abroad. At home there are at present several railway and waterworks projects of some magnitude in course of execution, and there are numerous smaller projects in the nature of sewage disposal, sewerage, small waterworks, and a few small and branch railways; but the total value of the whole lot does not probably reach ten millions sterling. A good deal of this work will take three or four years to complete, so that the home work at present in view does not offer very much reason for great expectations.

Canal engineering, which during the past few years has shown promises of revival, is still only promising, and even that chiefly in the form of improvement works not very likely to be taken in hand with sufficient vigour to make itself felt. Several of the more important projects, such, for instance, as the Birmingham and Worcester and Bristol Channel or Thames and Severn schemes, have taken the form of a compromise between a mere repair and reconstruction, instead of the execution of an important and complete scheme, or have been dropped, as in the case of a large northern counties amalgamation and improvement scheme which has virtually fallen into the hands of a railway company.

The Manchester Ship Canal, although improving in earning powers every quarter, has not encouraged other schemes of the kind, and, with the exception of a few of the more energetically managed canals, such as those of the Grand Junction Canal Company,[1] few of the many miles of existing English inland waterways can be said to be of much money-earning value. There is, however, without any doubt, a gradual awakening to the possibilities of many of these old lines of canals, and it may be expected that with the completion of some of the improvement works now in progress, and with the successful development of one or other of the means of slow-speed propulsion of canal barges now under trial, that canal transport will in the not very distant future again take a notable share of the slow and heavy traffic of the country. Our readers will have been kept pretty well acquainted with what is going on in this branch of engineering by their perusal of our occasional summary of information concerning "Harbours and Waterways," and with some of the more important projects and aspects of these branches of engineering as they have occurred during the past year we have dealt at more length on page 17.

Some tunnel works of considerable magnitude have occupied attention during this year, more particularly the Glasgow Harbour Tunnel and the Blackwall Tunnel;[2] the latter, which is the largest cylindrical iron-lined tunnel ever constructed under the bed of a great river, may be expected to be opened for traffic before the end of the present year. We dealt with it so fully in our last issue, that it is unnecessary to refer to it at any length here.

A tunnel which has been an exceedingly difficult one to construct, namely, the Sequixquiac Tunnel, for the drainage of the Valley of Mexico, was completed in October last, and the partial drainage of Lake Texcoco[3] by the new canal 29½ miles long, and the tunnel 6¼ miles long, has commenced, the drainage water passing into the Gulf of Mexico. A large tunnel project of the immediate future is the Simplon Tunnel, to which we referred in our last impression, the final arrangements having been made for carrying it out. We have fully described the chief engineering features of this big boring,[4] but we may mention that between the terminal points at Brieg in the Rhone Valley and Douro d'Orsola on the Italian side, the total length will be a few feet over 12¼ miles, or nearly three miles more than the St. Gothard. About two-thirds of the length from Brieg to Isello, in the Val de Vedro, will be driven straight upon a rising gradient of 1 in 500 for 9260 yards, to a short level piece of 656 yards at the summit, and thence on a falling gradient of 1 in 143 for 11,148 yards to the mouth on the Italian side. The contract price for the works is £1,900,000; the time allowed, 5½ years; and £200 per day for earlier completion or for delay.

Rapid progress is being made with a tunnel of very considerable interest to Londoners, namely, that of the Waterloo and City Electric Railway[5] under the Thames. Of the total length of this line the chief parts have been completed, including the whole of the portion which is under the Thames. The citywards heading is now past the *Times* office, and the watery section near Waterloo Station is progressing under air pressure. The engineers, Messrs. Galbraith and Greathead, and Messrs. Mowlem and Burt, contractors, are to be congratulated upon the rapid and successful advance they have made towards the completion of this railway. On the construction of tunnels of this kind a long promised paper was read by Mr. Greathead at the Institution of Civil Engineers on the 19th November[6]. Capital has at last been subscribed for the Central London Railway, and a commencement has been made towards realisation of this much needed means of communication between the City, the West of London, and Shepherd's Bush. The Hudson River tunnel must again be referred to as one of the partially completed works remaining in abeyance.

During the year the Glasgow Central Railway, of which Messrs. Forman and McCall are the engineers, has been nearly finished; the Glasgow District Subway, of which Mr. Simpson is the engineer, has been commenced and will be worked by cable; and the Glasgow Harbour Tunnel and Railway, under the same engineer, has been completed. In both the latter cases, iron-lined tunnels constructed on the shield system have been adopted.

Africa is at the present moment providing occupation for a good many engineers in the construction for the surveying for railways. Amongst these is the railway which has been commenced in Sierra Leone from Freetown to the interior. This will be about 100 miles in length, and is being constructed on 2ft. 6in. gauge. Another is being constructed from Lagos to the interior, and will be 120 miles in length. This line includes a bridge ¾ mile in length for connecting the port of Lagos with the mainland. Both these lines are being constructed under Mr. W. Shelford, M. Inst. C.E., by the Colonial Office, and the Lagos Railway will, no doubt, soon be followed by others in this country, teeming with wealth in natural products only waiting to be brought to the coast.

A much longer railway, and one of great importance, though perhaps not likely to be so immediately profitable, is the Uganda Railway,[7] for the construction of which Mr. George Whitehouse, M. Inst. C.E., has gone out as chief engineer. This line will probably be 670 miles in length, and already materials have been sent out for the construction of the first lengths. In China there is much hope of railway work, and English engineers have a good reason to expect that a large share of it will fall to them, some extensions being already in the hands of Mr. C. W. Kinder, M. Inst. C.E., whose name is so much associated with all that has been done in China in railway engineering.

So much progress has been made during the year with the construction of the Lancashire, Derbyshire, and East Coast Railway, that the greater part of the section between Chesterfield and Lincoln, together with the branch lines in the colliery districts between Langwith Junction and Beighton Junction will be ready in a few weeks for coal traffic. The part between Lincoln and the East Coast yet remains to be commenced, and that part which was included in the first plans between Chesterfield and Warrington will not be made. The parts which are most rapidly nearing completion are those between Chesterfield and Tuxford. The line, of which Mr. R. Elliott Cooper is the engineer, is being constructed by Messrs. Pearson and Sons, and comprises a great deal of very heavy work in cuttings, tunnels, and bridges, some of which we hope to illustrate at any early date.

Several other railways are being built in Scotland, including the East Fife Central Railway, of which Messrs. T. Meik and Sons are the engineers, and which is to open up new mineral fields. The Burntisland New Dock, under the same engineers, is to be commenced in the spring, and will cost £300,000. The Highland Railway extension to Kyle Akin, with a loop to Inverness; the Edinburgh new station, including the Haymarket and Calton Tunnels, for which Messrs. Blythe and Cunningham are the engineers; and the Lanarkshire and Dumbartonshire Railway, under Messrs. Forman and McCall, are making rapid progress towards completion.

In India a great deal of railway work has been completed in the last few years and a great deal is now under survey and in course of construction, a slight increase in the estimates for this purpose having been made and passed last year. The Adam's Bridge Railway project, to which we referred in our annual article last year, has been the subject of two official reports[8] since that date, but no steps have been taken towards its realisation.

Since we were writing last year the heavy floods in the Upper Thames, and particularly at and above Kingston, have caused criticism of the Richmond sluice and weir, and some hopes were raised that the proposal to erect near Hammersmith a similar set of sluices would be realised. It was, however, found that the reasons alleged by Hammersmith as to decrease in tidal water had no foundation in fact, and that another reason for the construction of the weir, which, no doubt, would beautify the river above Hammersmith, would have to be found.

A Bill is in Parliament this year for a big weir with sluices across the Dee at Chester, the object being in this case to prevent the pollution of the river above by the tidal waters that now pass up.

The floods last year showed once more the necessity for placing the whole watershed of the Thames under the authority of the Conservators, or some body specially formed, so that the whole watershed may be properly and differentially rated to pay for the necessary works of regulation. These rates would, however, not be very great, for at the same time that large storage and regulating reservoirs are being made for this purpose, they would provide the means of storing the water for the London water supply. This subject was considered by the Commission of 1892[9], and the valuable evidence then given ought to be utilised in this direction.

The project is one of great importance to Ceylon and Southern India, but its cost, including that of about twenty miles of bridgework, much of it of a very simple order, however, will, it is to be feared, keep it in abeyance for some time.

The completion of irrigation works on a very large scale by English engineers in Egypt[10] has added to the debt of that country to engineers for the amelioration of its cultivation difficulties. The great Nile reservoir irrigation project which is to do so much for Egypt, and in the way of which the ruins of Philæ[11] stand, has made small progress during the year, but that little progress encourages the hope that the interests of Egypt may not be sacrificed either to narrow prejudices or to international jealousies which have stood in the way.

A grand piece of irrigation and waterworks engineering, namely, the Periyar Irrigation Works, which is also a water supply and water power works, was completed this year, a work which included the construction of one of the high dams[12] of the country.

During the year the light railways question has been very much to the front, and a very largely attended international railway congress[13] held its meetings in the Imperial Institute last June and July. Since that time the Board of Trade has held an inquiry on the light railways question, and the report of a Committee appointed was published[14] in February last. This report did not very much help Mr. Bryce, then president of the Board of Trade, and since that time little has been done on the subject officially, but Mr. Ritchie, President of the Board of Trade, has visited Belgium and France with a view to obtaining his own notions of this subject on the spot. A conference has also been lately held in Westminster, headed by Sir Albert Rollit, and supported by many who are of opinion that light railways would be a great help to agriculture. There is no doubt they would in some localities, not very numerous, be a direct help to agriculture, but in most parts of the country they would only indirectly help by increasing or preventing decrease of rural populations, and by making possible a system of co-operation as to collection of farm produce and requirements as followed in Belgium. The construction of light railways can only be entered upon, however, where the total cost will be the costs of construction, and this can never be the case until parliamentary procedure[15] has been considerably modified, and Board of Trade rules and regulations changed to meet the requirements of light, slow, cheap railways.

In a great many parts of the country that help which has been hoped for, though more or less vaguely, from light railways will be very much more readily and cheaply afforded by means of mechanical road carriages and vans. By means of such vehicles, weighing with their load of passengers or goods not more than about two tons, and capable of speeds of say eight to ten miles an hour and two to three miles per hour up hills, farmers, carriers, and postmasters, would be placed in possession of all that is necessary to provide a service of vehicles on country roads which would have the regularity of a light railway service, but would possess much greater flexibility and far greater economy. From £100 to £500 per mile spent on improvement of country roads, where they are not already good, would with mechanical road carriages be in many parts more effective than from £100 to £2500 per mile spent on light railways.

The largest graving dock in the world, viz., that of the Southampton Railway Company at Southampton, was opened during the summer by the Prince of Wales. It has been constructed by Messrs. Lucas and Aird, is emptied by two pumps, 4ft. in diameter, by Messrs. John and Henry Gwynne, which lift over 540 tons of water per minute, and it is 750ft. in length, 87ft. 6in. wide at sill level, 112ft. 6in. at quay level, and has a maximum depth of 35ft.

Among the familiar problems yearly growing in difficulty of solution is that of the disposal of town refuse in London and the other large towns in this country. The old methods of sorting, utilising, and destruction have become obsolete. The refuse which in past days used to be sold to brickfield owners and men of the type of Dickens' Mr. Boffin, is no longer saleable, but towns have to pay heavily for the work of its disposal. The design and construction of refuse destructors has become an important branch of sanitary engineering, and the best design for furnaces for this work is yet a matter to some extent of opinion, more especially when the utilisation of the waste heat becomes a matter of importance. Where destructor furnaces are not employed the sanitary disposal of refuse, more especially from towns situated within the watershed of one or more of them, is a matter of great difficulty, and the conservators of rivers such as the Thames need have placed in their power summary jurisdiction to prevent serious pollution which is now possible.

In one of the most interesting and characteristic addresses which grace the proceedings of the Institution of Civil Engineers, Sir Benjamin Baker referred to some questions with regard to the Institution which have long occupied the attention of many of its members although the Council has paid but little heed to them. When the Charter of the Institution was first drawn up there were only 156 members; there are now 6794 of the various classes. These members are scattered all over the world and a considerable number hold important positions in different parts of this country. The conditions necessary to a sound representative government of the Institution have thus very materially changed, and some modifications have therefore become absolutely necessary in the constitution and rotation of the Council and its members in the bye-laws, as to voting for the members of the Council in the numbers to be placed on the balloting list, and in some of the customs as to elections within the Council.

MECHANICAL ENGINEERING.

In mechanical engineering there is little that is new to record. Three principal subjects have been discussed and considered and received all the attention available. These are water-tube boilers for the Navy, the acceleration of railway travelling, and self-propelled common road carriages. In one sense, the action of the Admiralty in adopting the Belleville boiler is of transcendent importance. Although the boiler is in use in the French navy, nowhere outside England has resort been had to it on anything like a crucial scale. It is not that it is being fitted to two great warships alone—although that would constitute an experiment remarkable for its magnitude—but that its universal adoption in the future forms a portion of the Admiralty programme. Our own views and reservations on the subject are well known. We do not believe that the boiler is either so bad or so good as its enemies and its friends respectively would have us believe. But bad or good, we think that it is not beyond the resources of British mechanical engineers to produce a boiler which ought to do its work as well and give as much satisfaction as anything that a French engineer can produce. English engineers have, however, in some sense themselves to thank. The situation had beyond question become intolerable. From one cause or another the Scotch boiler as modified to meet naval requirements would not stand the forced draught needed to get large quantities of steam from it. No English water-tube boiler was available to take its place. In considering the action taken by Mr. Durston and the Admiralty, it is constantly forgotten that, however bad the Belleville boiler may be, it is hardly conceivable that it will be worse than the boilers now in the Navy, if we judge by past experience. No one says that the Belleville boiler will break down or give trouble with natural draught. It is on all fours so far with the Scotch boiler. It is said that if pushed it will fail. That remains to be seen; but even if it does it cannot fail worse than the boiler whose place it is about to take. In dealing with the Belleville boiler we have said ere now that it is a steam-generating apparatus, not a boiler in the ordinary sense of the word, and it and its appurtenances must be dealt with as a whole. Because it was not so dealt with the s.s. Ohio has not been a success; but the major trouble was due in her, not to the boiler but to the feed-pump, which was entirely unsuitable for the work it had to perform. With ordinary boilers, so long as there are feed-pumps available to "slap it into" the boiler, everyone is satisfied; but the feed cannot be "slapped into" a Belleville boiler anyhow. This is not, as any mechanical engineer will see, necessarily a defect. In a word, the Belleville boiler must be dealt with in a special way because it is a special steam generator, and this is no more a radical defect than the circumstance that the boiler of a steam fire-engine cannot be handled like that of a tug-boat is a defect.

Concerning "express" water-tube boilers, their use is not only extending, but it has come to be regarded as indispensable in all the lighter craft which have to run at high speeds. There are a number of such boilers now recognised as out of the region of theory. Among these, to say nothing of the Yarrow, the Thornycroft, and the Normand, are those of Mr. Blechynden, Mr. Mumford, Mr. White, Mr. Des Vignes, and one or two others. In the United States there are a number of water-tube boilers claiming recognition, many of which possess features anything but commendable in English eyes, as, for example, a multitude of screwed and running joints, and pipes so contorted that to clean them seems impossible. While on the subject of joints we may call attention to the revival of the copper wire joint first devised by Jacob Perkins, of steam gun fame. The credit for this revival is very largely due to Mr. Mumford, of Colchester. It is, of course, easy enough to say of it, "Oh, we knew of it all along;" but the fact is that it has not been used, and that at this moment it is not everyone who knows how to make a proper copper wire joint—a joint, it is perhaps right to add, that must not be confounded with a wire gauze joint.

In the United States a modification of the Babcock and Wilcox boiler is being used for marine purposes, especially in lake steamers, and an endless variety of express boilers are being fitted into launches, and yachts, and small craft, and for each it is claimed that it is very much the best of its kind in the world. At this side of the water Mr. Howden's system makes steady if slow progress, and the same may be said of the induced draught system made by Messrs. Sir John Brown and Co. A most successful application of induced draught has been effected by Mr. Bevis in the paddle steamer Queen of the North, already fully described and illustrated in our columns.

The necessity for the use of pure feed-water is daily becoming more fully recognised, and all ships are now fitted with the filtering and purifying appliances of Weir, Normandy, Mudd, Maudslay Sons and Fuld, and many other makers. In the Navy "The Compactum" of Messrs. Kirkaldy seems to enjoy most favour at present. It is to be fitted in the Sultan, Hannibal, Jupiter, Illustrious, Minerva, Gladiator, Andromeda, Recruit, Vulture, Foam, Desperate, Mallard, Fame, and also fourteen complete sets for first-class torpedo boats, and feed-water filters for H.M.S. Talbot. The six torpedo destroyers Sturgeon, Skate, Starfish, Handy, Hart, and Hunter have all been similarly fitted.

In the marine engine little that is novel has been achieved, and the same thing may be said of steam engines generally. Joy's hydraulic gear is gradually creeping into use, and during the year we have illustrated a gear which has been devised by Mr. Marshall and used with great success by Messrs. Fowler, of Leeds. The system of constructing high-pressure compound engines, like triple-expansion engines with the intermediate cylinder left out, continues to give excellent results, and is growing in favour as a means of improving the performance of steamers with ordinary compound engines, with a minimum of alteration and expense.

It can scarcely have escaped our readers that the performance of mill engines appears to be gradually improving. A competition exists among the more eminent makers, who manifest a desire to break the record, and the tests which are now carried out by such men as Mr. Crosland, Mr. Longridge, and others, have been so systematic that the results obtained, however startling, are commonly irrefragable. At the same time it must be admitted that much remains to be settled before any satisfactory and consistent theory of the steam engine can be proposed, the influence of the steam jacket being especially puzzling. The jacket committee of the Institution of Mechanical Engineers has not yet reported. Bearing on cylinder condensation is the statement that Mr. Henry Davey has designed and is constructing a very powerful pumping engine on a new principle; nothing less, in short, than a compound engine working on the Cornish cycle, and with very special arrangements for heating the feed-water. We shall illustrate this engine in an early impression, and till then we shall say nothing more about it. In high speed engines the only new departure appears to be the Peache engine, made by Messrs. Paxman, Davey, and Co., of Colchester. The engine has been so recently illustrated and described in our columns that we need not further refer to it.

A very remarkable traction engine has been constructed by Messrs. Burrell, of Thetford, which seems to set certain well-known mechanical laws at defiance. In this engine speed is first got up in the gearing, and then let down again, roller bearings being used in a way which would not be intelligible without the illustrations which we hope to publish in a little time. The result is that the engine in the quick speed will haul as much as two other engines did in their slow speed. The true influence of ball and roller bearings does not appear yet to be understood. Very careful experiments have been carried out with a bicycle, in which the axle bearings were got up with the utmost care and perfectly lubricated. In spite of the small size of the axle, however, it was found that in practice the resistance of the machine was incomparably greater than that of a precisely similar bicycle with ball bearings. It is impossible by any manipulation of figures to explain why these things should be, but there they are, nevertheless.

Our friends in the United States tell us that they have taught us in this country how to run trains at high speed. It remains to be proved that the contention is sound. But we are willing to admit that men like Mr. Buchanan have achieved great things. Two noteworthy facts about American locomotives for high speeds are worth stating; one is that at the other side of the Atlantic engines of very great size are employed—engines with 50 per cent. more heating surface at least than is used in this country; another is the very heavy consumption of fuel; and, lastly, the great height of the centre of gravity above the rails. It is quite true that no locomotive has ever been overturned unless by the sinking of a rail, so long as it kept the track, and it can easily be shown that the higher the centre of gravity the less is the bursting effort of the engine on the road; but it must not be forgotten that the lurching of the engine augments as its centre of gravity is raised, and that this lurching tends to force down the rails, to break the springs, and otherwise to do mischief. There is, in a word, a happy medium which should be observed, and no doubt very great care must be used in packing up roads on which these exceedingly lofty structures run at speeds of seventy miles an hour or over. When we read of the velocities attained according to some of our American contemporaries, we often wonder whether Professor Osborne Reynolds is prepared to modify some of the statements contained in an able series of articles on "Limits of Speed" from his pen which appeared in our pages some few years ago. Concerning the race to the North, it has been so fully dealt with in our pages already by Mr. Rous-Marten, who will have something more to say on the subject by-and-bye, that it is not necessary to do more than name the matter here.

The movement in favour of self-propelled vehicles for use on common roads has become too forcible to be resisted. It is not confined to those who would use such carriages for pleasure purposes, nor to a single county. Omnibus companies regard with pleasure any scheme for getting rid of the horse; and the advantages conferred on street traffic by the substitution of steam, oil, gas, or electricity for animal power are far too obvious to require explanation. There are obvious reasons why we should not attempt to indicate here the direction in which success is most likely to be attained. It is expedient, if not necessary, that we should confine ourselves to describing what is being done, instead of attempting to prepare a forecast of what will be done. In another page our readers will find an account of the latest developments of the self-propelled road carriage, "Auto-car," "Non-equine," "Motor-car," or whatever name popular taste will finally confer on the horseless vehicle. Here we shall content ourselves with stating a few historical facts which are not generally known.

We have only to read what has been published concerning the work done by Gurney, Dance, Maceroni, and several others to learn that a very considerable success was achieved. Such a carriage, for example, as the Autopsy was not a toy; and Hancock's steam omnibus, the Enterprise, which plied between Paddington and the Bank, was a very real and practical machine. Why the use of steam on common roads was abandoned supplies a curious episode in history. About the years 1828 and 1830 locomotion by horses had been brought to the greatest perfection of which it was capable. The mail coach roads which traversed the country were the finest highways in the world. An enormous number of horses specially bred for the purpose was engaged in working mail coaches which embodied every perfection that the art of the coach builder could devise. On the crack mail routes the average speed, including stops to change horses, was ten miles an hour. The regulation time for changing was one minute. Much galloping was done, and to obviate certain abuses an Act of Parliament was passed in which was a clause which enacted that all the four horses of a mail coach must not gallop at once, under a penalty. The proprietors of the coaches got over this difficulty by providing in each team one first-class trotter, who was known as the "parliamentary horse"; he cost as much money, probably, as any other two, but he could trot as fast as they could gallop. It was felt, however, that the limit had been reached, and that no acceleration of the mails was possible. It was to get over this difficulty that Hancock, Dance, and others devoted themselves. The mail coach proprietors, horse breeders, coachmen, and a whole host of persons more or less closely interested in the enormous coaching and posting trade of the country, were quite astute enough to see that if the steam carriage was a success the days of the horse-drawn mail coach were ended. The result was an intense opposition. But this would have been overborne by the national necessities had it not been for the advent of railways, which provided a means of transport infinitely superior to anything that could be put on the highway. All the capital and enterprise of the country went into railways, and no more was heard for many a day about steam on common roads. When Boydell, Burrell of Thetford, Smith of Coven, Aveling of Rochester, and Fowler of Leeds came on the scene, they worked on entirely different lines; but it is worth notice that the opposition they had to encounter arose mainly with the turnpike trusts. Curiously enough, the traction engine in 1862 and for some time subsequently could travel about the country without paying turnpike dues. It is very erroneously assumed that it was the proprietors of horses who have practically penalised the traction engine, but this is not the fact. The horse and his fright have been used as pegs to hang contentions on, but if only the traction engine users had in the first instance made friends with the turnpike authorities, instead of fighting them, much trouble would have been avoided, and the self-propelled road carriage would be an accomplished fact instead of something yet to come.

In locomotive construction little or nothing new has been accomplished during the year. The tendency is to fit all fast running engines with bogies. The bogie is by no means a special favourite with locomotive superintendents. It is very heavy; it adds about £150 to the cost of an engine; it requires a good deal of scheming to combine it with inside cylinders more than 18in. diameter; and it costs something for maintenance. But the civil engineer likes it. There is no question that the bogie spares the permanent way. It relieves cross-stresses, it does not tend to burst curves, and the leading wheels seem to settle down and consolidate the road. The very heavy loads put on driving wheels now and for some years past are borne very well by steel rails; but tracks are not composed of steel rails only, and the civil engineer of a line has to think of sleepers, chairs, and ballast, as well as rails. The quicker a train runs and the heavier the engine the greater the good done by the bogie, and we believe that in the near future all express engines for main lines, with cylinders not less than 18in. in diameter, will have bogies.

As to boiler construction, we hear of little that is new. The boiler is the most costly and troublesome part of a locomotive. It is now, however, what it was thirty years ago, and no one seems to be able to effect an improvement. Various more or less remarkable devices have been tried on the Continent, but the results do not seem to supply a departure from normal practice. Mr. Holden, however, on the Great Eastern Railway, is using Serve tubes with much success. He has now a four-coupled express engine, No. 712, fitted with his apparatus for burning liquid fuel. The boiler, which is fitted with Serve tubes 2¼in. external diameter, has been successfully fired with oil alone, without the necessity of a fire-brick construction in the fire-box, the bars remaining as in a coal-burning engine, but simply covered with a layer of about 6in. of broken fire-bricks. The consumption of fuel in this engine has been 17 lb. of oil per mile. The steam is first raised to a pressure of 20 lb. per square inch with wood. The liquid fuel storage at Stratford has been improved, and the plant now consists of underground reservoirs of 37,000 gallons capacity, from which the oil is pumped by means of a rotary pump into a high-level tank of 4000 gallons capacity, from which the engine tanks are filled by gravitation. The ribs in the Serve tubes act not only as collectors and transmitters of heat but as retarders, owing to increased skin friction. The result is a considerably reduced temperature in the effluent gases.

Concerning the compound locomotive, the evidence is so conflicting that it is quite impossible to arrive at any conclusion except that it is at least as good as the non-compound engine. In the United States it enjoys high favour on some lines, on others it will not be employed at any price. Nor is there any tangible reason available for its success in the one case and its failure in the other. So far as we can arrive at any conclusion, it is that when engines are regularly heavily loaded compounding will effect a saving in fuel of about 9 per cent.; when an engine has light loads to haul compounding is a direct source of loss, the cylinder capacity being much too great. Thus an engine may run for a month on variable traffic, losing one day what has been gained another, and this is, we believe, the main cause of the difference of opinion. We are quite aware, however, that it does not cover the whole ground of discussion in this country or abroad. Some discussion is now taking place on the subject of grates in the United States, and we learn with surprise that in some cases "as much as 200 lb. of coal are burned per square foot of grate per hour." As a matter of fact, however, we do not believe this possible. A draught sufficiently powerful to do this would carry the coal off the bars bodily. Coal may ostensibly be burned at that rate; but we believe a large percentage goes up the chimney unconsumed. It is not remarkable that, under such conditions, an augmentation of grate area is desirable. We have so often dealt with American train speeds, that it would be waste of space to touch on them here. It is noteworthy, however, that the single driver engine is at last coming into favour at the other side of the Atlantic.

Although we have dealt with electricity in another place, we must refer here to the greatest experiment ever made in electric traction. We refer to the 90-ton electric locomotive working in the Baltimore Tunnel. We have given particulars of its performance on several occasions. From a recent report, however, we learn that during a recent test it hauled a train weighing about 1300 tons through the tunnel, the electrical energy transmitted to it being 3000-horse power, which does not speak much for economy.

During the past year there have been a few remarkable boiler explosions, and a number which have done very little harm. The Redcar catastrophe is an example of one type of failure. An explosion very remarkable for its fatal consequences occurred in the United States at Detroit, on the 6th of November. A boiler used for driving printing machines burst. It was one of two horizontal tubular boilers 5ft. in diameter, and 14ft. long, externally fired with oil. The greatest reticence has for some reason been observed. We know little more than that the five-storey building fell down, and that thirty-seven persons were killed. Another terrible explosion occurred at Denver on the 18th of August, when a boiler used for working the elevator and heating the Gumry Hotel gave way, demolishing the building and killing twenty-two, and severely injuring about twenty other individuals. Prudence suggests that in the United States boilers should be put on the top of the buildings instead of in the cellars. On the 18th December a dreadful accident occurred on board the new American line steamer St. Paul. A cast steel elbow in the main steam pipe leading to the starboard engine blew out, allowing steam from the boilers, which were under pressure of 130 lb., to fill the engine-room. This resulted in the killing of five men outright and the scalding of four others so badly that they died in the course of the day, while four others had to be taken to a hospital. The accident took place in New York a short time before the hour of sailing. The explosion took place while the main stop valve, 17in. in diameter, was being opened to admit steam to the jackets. Little damage was done except the smashing of the glass in the skylight and the breaking of the short pipe leading from the throttle valve to the cylinders. The main steam pipe, it is said, is of copper, with a number of expansion joints to render it elastic, and the condensation from pockets in the steam main is removed by means of traps. The steam pipe was only under pressure of 130 lb. at the time of the accident, while 200 lb. is the pressure carried when at sea. From the facts gathered it would seem that water-hammer caused the accident.

During the past year an enormous development of the cold transport and cold storage system has taken place. Probably the British farmer has no greater foe to dread than the refrigerating engineer. We can do no more here than refer in general terms to what is being done in this direction. The Haslam Foundry Company, of Derby, for example, during the past year has fitted up with dry air refrigerating machinery, worked on the compressed air principle, one steamer to carry 2000 tons of meat; four steamers to carry 1000 tons each; two steamers to carry 500 tons each; one steamer to carry 400 tons; and has in progress machines on the dry air system for fitting up three steamers, each to carry 1000 tons of meat; two steamers, each to carry 600 tons of meat, or an equivalent amount of dairy produce. Two of these steamers are for the P. and O. Company, for its new boats China and India, which, we believe, will be among the largest and most improved mail boats in the world. In addition to this the company has supplied a number of machines to the Austrian Government for use on their men-of-war, on the compressed air principle, and also for a number of men-of-war and cruisers for the Russian Government. It appears, therefore, that the dry air system is by no means extinct. The company, however, does not confine itself to air machines. It is fitting the s.s. Southern Cross at the present time with a new patent ammonia compression machine; this boat will carry 2000 tons of meat. With regard to shore machines, which have been erected on the ammonia compression and absorption systems, the company has supplied sixteen large ammonia machines, the most important works being the large stores at the East and West India Docks, to hold 4000 tons of meat; a large store at the North-Eastern Railway Company's Docks, Hull; one large size machine at Meux and Co.'s Brewery, London, equal to 85 tons refrigeration; two large 50-ton machines have been supplied and fixed at the Broxburn Oil Company's Works; and Young's Paraffin Oil Works, in Scotland. But perhaps the most interesting contracts which the company has taken are for the Gladstone Meat Company, Queensland; for the Australian Chilling and Freezing Company, New South Wales; and one for the Melbourne Freezing Company, Victoria. These three plants will be capable of freezing 1000 tons of meat each per month, and are to be fitted with a newly patented corrugated brine battery. A similar plant has also been supplied to the River Plate Fresh Meat Company, London, for its works in South America; and the company will in a short time erect a large chilling plant for the Corporation of the City of London, for chilling 2074 sides of beef per day. This plant will be the first of its kind applied in this country, and we shall probably illustrate it in an early impression.

But even a statement such as this gives a very inadequate idea of what is being done. Thus, 322 ice making and refrigerating machines have been sold by the Linde Company during the year. These 322 machines possess a refrigerating effect equal to that produced by the melting of about 7000 tons of ice every twenty-four hours. The total number of Linde machines sold up to the end of the present year has reached the enormous figure of 2400, the refrigerating capacity being equal to about 60,000 tons of ice melted per twenty-four hours. Of these about 1300 are in use in breweries, the remainder being used for meat freezing and storage, ice making, and a multiplicity of other purposes. The Linde machines are much used on board ship for the carriage of frozen meat, dairy produce, &c. We may specially mention the large meat carrying vessels of Messrs. Turnbull, Martin, and Co., the New Zealand Shipping Company, the British India Steam Navigation Company, and R. M. Hudson, of Sunderland. Another application of the Linde system now receiving considerable attention is in the conversion of existing compressed air machines. These conversions are taking place in Australia and New Zealand, as well as in this country, As an example, we may cite the Mersey Dock and Harbour Board, who are now having a compressed air machine converted to the Linde system. When this is done two tons of coal will chill more beef and in a better manner than can now be chilled with ten tons of coal. This is no mere guesswork. The Dock Board have now three Linde plants in operation, so that the result of working is well known. In Australia a marked advance in meat freezing has been made this year by the successful opening of the new freezing works of the Queensland Meat Export Company, at Townsville and Brisbane. The machinery was supplied by the Linde British Refrigeration Company, which has also orders for similar plants for Rockhampton, Bowen, Geelong, and many other places. There has also been a distinct advance in this country in the application of machinery for ice making; with proper appliances it can be produced at a much less cost than it can be imported. Linde plants are now being erected at Boston, Aberdeen, and Hull. For real ice skating rinks the Linde British Refrigeration Company has brought out a very simple arrangement for freezing the surface. There are neither cells nor pipes, so that the first cost of the plant is much reduced. Several skating rinks are now being laid down on this system. Several other firms, including Messrs. Louis Sterne and Co. on the De la Vergne system, are engaged in the construction of freezing machinery.

Messrs. J. and E. Hall, of Dartford, who are among the pioneers of refrigerators, have fitted during the past year, and have in progress, machines on their patent carbonic anhydride system — one large machine for the Government Gunpowder Works, Waltham Abbey; three installations for the Russian Government Gunpowder Works; second installations for the South Australian Government, Queensland Government, Victorian Government, West Australian Government; a large cold store adjoining Smithfield Market, for the London and India Docks Joint Committee; and also for Messrs. Lovell and Christmas, the Bristol Docks and Harbour Board, and the Bolton Corporation; an oil cooling plant for the Assam Railway and Trading Company; a plant equal to 200 tons of ice per day for Messrs. Mann, Crossman, and Paulin; a plant equal to 200 tons of ice per day for Messrs. Truman, Hanbury, and Buxton. For the National Skating Palace Company, Limited, London, the refrigerating machine and new patent ice flooring have been supplied, and also for the Glasgow Real Ice Skating Palace, Limited, to say nothing of a large number of small installations. Amongst ships fitted we may mention the s.s. Gothic, previously fitted with their carbonic anhydride machinery—she brought the first successful cargo of chilled beef from New Zealand during 1895, the prices realised being equal to that for American chilled beef—H.M. Niger Coast Protectorate steam yacht for preserving provisions, &c.; H.I.H. the Czar's new yacht, the s.s. Standart; the new White Star Liner s.s. Georgic, fitted to carry 3000 quarters of chilled beef; the s.s. Doric for the same company; Messrs. Houlder Brothers and Co.'s s.s. Ovingdean Grange, to carry 2000 tons of frozen meat. The firm are now fitting the s.s. Urmiston Grange, to carry 2000 tons of frozen meat; s.s. Elstree Grange, to carry 2000 tons frozen meat; s.s. Langton Grange, to carry 3000 tons frozen meat; Messrs. J. B. Westray and Co.'s s.s. Duke of Sutherland has been supplied with a machine to replace a cold air machine; T. B. Royden, of Liverpool, s.s. Indraghiri, to carry 2000 tons of frozen meat; the Hamburg American Steamship Company, refrigerating machines for seven new ships about to be built; Chargeurs Reunis Co., three ships now building. It will be seen from these figures that the refrigerating business is rapidly assuming enormous proportions, and it is satisfactory to note that the great bulk of it is placed in English hands.

Within the limits at our disposal it is impossible to notice many developments which mechanical engineering is undergoing, in various directions. But before taking leave of this branch of our subject, we wish to call attention to a somewhat suggestive fact. In the United States there appears to be a large demand for a variety of machines, and appurtenances of machines, and apparatus, about which we hear next to nothing in this country. Inventors not only seem to be prepared to meet every want, but they take measures to create that want. They tell manufacturers, for instance, that they would be much better off if they had such and such a thing, and then they supply the thing. As an example of what we mean, we may say that in a recent issue of *Power*, we find nine advertisements relating to improvements in indicators and their appurtenances; five tops for steam exhaust pipes; ten steam separators; sixteen feed-water heaters; and injectors, water gauges, grates, damper regulators, and such like without end. All these things are different. How is it that in this country the trade done in such matters is apparently very small? We fear that the mechanical engineer in this country does not lay himself out to make a good thing and sell it to nearly as great an extent as his rival in the United States. There are many things that the steam user would take and be glad to have if they were brought properly before him. Stop valves, for example, are, it may be said, insignificant details. How many really first-rate stop valves fit for large powers are there at this moment available at a moderate price? Anyone can make a valve suitable for low pressures. Why should it be so difficult to get hold of a sight-feed lubricator that will stand high-pressure steam? Dozens of things about which next to nothing is known in this country are made and sold by hundreds in the United States. We can do no more than give our readers a hint; possibly some of them may see their way to act upon it. But we cannot help adding that to produce a good thing, and to fancy that purchasers will be found, although no particular care is taken to make it known, is certain to end in disappointment. It is the want of publicity that spoils trade, a fact which our American brethren have fully mastered.

WAR MATERIEL.

In war materiel battleships claim the first place. The class of heavily clad battleships constructed by Sir W. White, and especially exemplified in the Royal Sovereign and Majestic classes, remains the fashionable type, the horizontal armour, barbette mounting, and other features being found, more or less, in the navies of most Powers, including Austria, Brazil, Italy, Japan, Russia, and the United States. France has at last condescended to adopt guns mounted in pairs instead of singly, in her Charlemagne type. This, however, is no new story, most of the ships referred to having been long laid down, although the most powerful vessels are only now coming into commission, or are still under construction. The favourite ship, however, at present, is a swift cruiser carrying an entire armament of quick-fire guns, and trusting mainly to her great powers of attack, although furnished with an armoured deck, shields to her guns, and in many cases with an armoured belt. This class of ship owes its importance in a great measure to the development of quick fire, and as is naturally to be expected, the most notable examples have been turned out at Elswick, such as the Esmeralda, whose power of fire has been recently noticed by us, the Buenos Aires, whose firing trial we recently reported, and the Blanco Encalada. Our own cruisers are, however, of a different type. Their displacement is enormous, in the case of the Terrible and Powerful reaching 14,200 tons. The French have followed a very different line, the displacement of the largest French battleship, the Bouvet, being 12,200 tons, the largest new French cruiser being the Pothuau, of 5345 tons. This is a decrease compared with the Dupuy de Lôme, which was 6297 tons. These are all less even than the Esmeralda, above referred to, which is building for Chili, and is 7300 tons. Russia led the way in large cruisers with the Rurik, which recently visited Portsmouth, of 10,923 tons, and she is now building the Rossia, of 12,130 tons. Here again the line to which we call attention has been followed for some time. It remains true, however, of the present moment. Our cruisers carry large supplies of coals and ammunition, and considerable quantities of armour in the form of horizontal decks and so-called casemated gun positions, which may be described as cells with thick shields in front, and thin walls, completely enclosing those in board—walls which are sufficiently strong to keep out splinters, and probably sufficiently complete to keep out gas from shells bursting near, but, as some naval officers think, increasing the difficulty of maintaining efficient fire control. In the United States ships the gun positions are surrounded by a double wall of thin plating, with many doorways cut through both walls, but not opposite to each other. By this means the fire is more under the immediate control of the commanding officers, and the guns may be protected from splinters, though not from gas, for there are many entrances to the position open at all times. Electric power is now applied to the working of guns on board ship. This has been done at Elswick, and in France by Canet, and is to be seen in the mountings of the 9·2in. guns for the Powerful and Terrible at the arsenal, as well as elsewhere.

France has had brought home to her the evil of allowing different sets of authorities to add to, or modify the designs of ships, the Hoche, and ships of the Magenta, Charles Martel, Requin, and other classes having had their stability so far interfered with as to jeopardise their safety. Happily for them this was discovered in time to prevent any such catastrophe as occurred with our ill-fated Captain. Great waste of money and loss of intended efficiency had to be accepted, and the ships were in a considerable measure cut down, the Brennus going back to dock just when she was expected to take her place in the fleet. The photographs we published in July showing the changes made in the Hoche give a good idea of what is necessary in others, though in a less degree. The after military mast is removed, being replaced by a light mast, parts of the superstructure are cut down and the armament is slightly curtailed.

The main cause of the mistakes has been the wish to accumulate gun positions, and to give them high command above the sea. The French designers and constructors were not to blame, but the system of allowing their designs to be "tinkered" by those whose knowledge of construction was inferior to their zeal to obtain great offensive powers.

It is questioned whether the same action has not been carried out in the United States, and whether some of their ships, with their imposing array of gun positions, might not be found deficient in stability if tested. Certainly we may learn from the difficulty of multiplying guns placed in armoured positions to hail any extension of quick fire to pieces of larger calibre. The Elswick 8in. quick-fire gun is now supplied in cruisers, and may be said to be afloat, and liable to be encountered in action. This is probably the largest gun in which quick-firing can be performed by hand, but this does not prevent the principles of quick-fire, in modified form, being applied to heavier guns. The principle of quick-fire may be said to be carried out to the fullest extent, indeed, only in small arms, where fixed ammunition carrying its own ignition is automatically carried on a band to the breech of the piece, which loads and fires itself at the rate of 600 or even 900 rounds a minute. With increase of calibre the automatic action gives way to semi-automatic, where the ammunition has to be thrown by hand into the breech, the next step is the separation of the brass case from the projectile, a principle which came early into use in England, and at last in spite of long maintained refusal, has been accepted abroad. At a higher stage the brass case has to be discontinued and asbestos packing relied on, but still the rapid opening and closing of the breech by the single movement of the arm may be maintained, and the speed of loading and firing greatly accelerated. The importance of this may be appreciated when we remember that each extra gun involves carriage and armoured protection, with all the complications involved in the crowding of gun positions and increased tonnage. The enormous displacement exhibited by our new cruisers has suggested the question whether it would not be well to make some, at all events, on the lines of those turned out at Elswick. That is to say, to sacrifice the great supply of coal, and other special arrangements, for the sake of obtaining the great fighting powers and high speed that it has been shown possible to secure in a cruiser of comparatively small displacement. Such a cruiser would surely be of the greatest value, though her limited coal supply would prevent her from taking the long voyages that might be accomplished by her larger, much more costly, and less formidable sister. The efficiency of quick-fire depends on the use of smokeless powder, and we may congratulate ourselves that while cordite has given us such trouble in manufacture, the finished article as issued for service has so far proved itself thoroughly stable and safe under the most trying conditions, while it has given excellent ballistic results; in fact, to say that it has established its character as thoroughly, probably more thoroughly than any other smokeless powder, is hardly to do justice to it. On the Continent smokeless powders, chiefly based, like cordite, on the combination of nitro-glycerine and cotton, are used, but in the United States, strange to say, so great is the distrust of such powders that nothing better than a semi-smokeless powder of unsatisfactory behaviour has been allowed to be used on board ship. It seems probable, however, that before long the United States naval authorities will cease to keep their ships at so crushing a disadvantage, and satisfy themselves that the dangerous and treacherous element nitro-glycerine alters its character in the condition in which it exists in cordite. On the other hand, the United States Navy have been forward to adopt high explosive bursting charges for their shells; recent experiments, however, instituted owing to reports from the seat of the Chinese and Japanese war, showed that powder produced greater effect than wet gun-cotton, and it is anticipated that powder will be reverted to in America.

Passing on to armour, we find the United States, far from lagging behind, is here in the very front of the race of progress. England is found refusing to use nickel for thick or medium armour, because she could in an early stage make harder and cheaper plates without it. Other nations saw the value of the great toughness promised by nickel if certain difficulties of working could be mastered, and have been rewarded by making, we fear, better armour than ourselves. It is not easy to compare trials made under different conditions in different countries, though shrewd suspicions may be entertained. Here, however, is a definite fact. In the United States a really good nickel treated plate will defeat a Holtzer 6in. projectile. Till our treated plates do the same we are apparently left behind. Then, while we seldom test really thick treated plates, the United States authorities do so and have achieved most striking success with them, especially with what are called "double forged" plates made by Carnegie. Double forging is the natural remedy for crystallisation and weakness produced in very thick plates by the Harvey process, but double forging is untried in this country.

At length, however, we are glad to hear that our armour-plate manufacturers are alive to what has been done abroad, and are making efforts to push forward. At the Atlas Works—Brown's—nickel steel experimental plates are in course of manufacture, which will be ready for trial in a month. One of them has been forged after cementation by a process which is doubtless very similar to the re-forging carried out in the United States, though taken up some time since—before the American results were known here. Messrs. Vickers are also alive to the desirability of developing nickel-steel armour, so that we may shortly hope to see good results.

While hitherto neglecting nickel in vertical armour, we have happily succeeded in making thin nickel steel plates for decks and structure of ships with peculiar properties, and consider that in them we have a strong element embodied in construction. Passing on to shot, even the excellent Carpenter projectiles of large calibre, made in America, appear now to have been beaten by those known as the Wheeler-Sterling make. We know of no achievements in this country to compare with what these projectiles have done. Hadfield, for example, has made excellent shot, both forged and cast, and we should be glad to hear of achievements rivalling or beating those in America; perhaps if we made and tested on the large scale carried out in the United States we might have such records to show.

With ever increasing velocities we might have expected to have had to record bursts of guns during the year. This has not been the case either in England or on the Continent. The smokeless powders lend themselves to the achievement of very high velocities, combined with a low maximum pressure. In *Brassey's Annual* for 1895 the 8in. Elswick quick-fire guns, 44·6 calibres long, had muzzle velocities of 2260 and 2813, with 210 lb. shot. Canet has a 5·91in. (15 cm.) quick-fire gun, 60 calibres long, with 2822 foot-seconds muzzle velocity, with a projectile weighing 88·19 lb. In a new table just brought out this is increased to 2953 foot-seconds velocity. The Canet gun is a specially long coast piece. A 12 cm. (4·12in.) gun carried to the extreme length of 80 calibres is seen also with a velocity of 3281 foot-seconds. With any given powder and length of bore, English and Russian guns ought to take the lead in energy if desirable, seeing that in these countries only have wire guns come in. The highest velocity in a regular service British quick-fire piece is 2456, achieved by the 4in. wire gun. This is a piece of only 40 calibres long.

It can hardly be said that the year has shown good results for the very small bore rifles adopted by almost all military Powers. The bullet has a smaller diameter than a common cedar pencil—in the British service 0·303in. Its trajectory is very flat, and its velocity was said to be so high that bone splintered into shreds. Some trials on carcases showed that singularly little harm was done in perforating flesh, but it was explained that in living bodies the inelastic moisture present was violently thrown outwards, and enormous holes made. This was illustrated in lecture experiments with moist clay and the like. This was too readily accepted, suspicion should have been aroused by the fact that wild animals grazing did not always find out when they were hit; and still more direct evidence was afforded us when a collier, shot through the thigh in a riot, walked about for an hour or two fancying that he felt something, but not troubling much about it. Now evidence has poured in from opposite quarters of the world to the effect that the small bore is singularly deficient in stopping power. It might be said, indeed, to have the opposite effect, for a retreating Chinee is thought to have had his pace rather accelerated as a rule when struck by a Japanese small bore bullet. Medical reports from England, the Continent, and America, show that the wounds made both through flesh and bone give generally remarkably little trouble, and heal with great rapidity. Our troops recently sent to Ashanti have been armed with the old Martini carbine of 0·45in. bore, nor can we wonder. Savages who have not had the advantage of hearing the lecturer prove the effect of the bullets to be so terrible, would, we fear, take little or no notice of bullet wounds made by the 0·303in. bore, unless they struck in a really vital place, such as the brain or heart, and these organs are perhaps not specially large in savages. Seriously, something will have to be done about the small bore bullet; perhaps the partial removal of nickel covering may cause setting up of the bullet to a reasonable size on impact. If this is contrary to the Geneva Convention, might it not be laid down that a civilised soldier must retire from action after a certain number of hits, say, two or three? For it appears that even this number have not always caused serious inconvenience at the time.

HARBOURS AND WATERWAYS.

The chief feature of the past year in connection with accommodation for the shipping trade has been the numerous works that are now in contemplation or in progress for the purpose of adapting tidal rivers, harbours, and docks to the continually increasing size and draught of vessels; and the attempt that is being made, and to a great extent successfully made, by our continental rivals to attract to their ports commerce of which hitherto we have had almost a monopoly.

In providing for the demands of modern steam vessels, Southampton, under the energetic management of the South-Western Railway, has taken the lead, and has already stolen from Liverpool a large slice of the American traffic. The graving dock which was opened during the year is claimed to be the largest in the world. The other works for giving quicker facilities to the navigation are making rapid progress, and already the large increase in the trade which is taking place at this port justifies the inception of these works.

Liverpool also has not been standing still, considerable progress having been made with the new lock and other works for making provision for deep-draught vessels. A new passenger station at the Prince's Landing Stage has been opened and the river dredged, so as to allow the large steamers to land their passengers at the stage without the use of a tender. The dredging operations on the bar have been continued, and this no longer affords an obstacle to the navigation, there being now 24ft. at low water, of spring tides over a width of 1400ft.

Considerable activity in works of improvement has also been going on at the coal ports in Wales. Not only is the Bute Dock Company providing for deeper draught vessels and more shipping accommodation, but a new company is applying to Parliament for powers to construct a deep-water dock. A new dry dock of large dimensions is also in course of construction. Further works are also contemplated at Swansea; and at Port Talbot the works for making the new deep-water dock and approaches, for which Parliamentary powers were obtained last session, have been commenced. This dock, which it is expected will be completed in two years, will afford an outlet for a large coalfield which is to be opened out. Llanelly also has a Bill coming on next session, giving power to construct a new cut and dock entrance, and otherwise improving the access to the port; and the Great Western Railway Company is contemplating improving the entrance to its dock.

At Hull the North-Eastern Railway Co. has already commenced making improvements in the docks of which it became owner last year; and other works of considerable magnitude are in contemplation. At Grimsby it has been announced by the Manchester, Sheffield, and Lincolnshire Railway Company that the dock accommodation is to be considerably enlarged; but the alteration will be principally for the benefit of the fishing trade. At Boston, where it is expected there will be a considerable increase of traffic when the East and West Coast Railway is opened to Lincoln, the river is to be deepened throughout, so as to give 27ft. at high water of spring tides. At Leith the construction of the new sea wall and the works for the new dock have been proceeded with, the difficulties which arose owing to the death of the first contractor having been overcome. The new Cessnock dock on the Clyde, although not finally completed, has been partially made use of. Preston also is seeking further power to improve the working accommodation at the dock and the approach from the sea. The Bridgwater Trustees have given instructions for a report to be made as to the best means of improving the navigation of the river Parrett, in which a considerable coasting trade is carried on, but which, like all other ports, is calling out for deeper water. The Bristol Corporation have made very little advance during the past year in the various schemes which have been proposed for providing for deep draught ships. The whole matter, including the dockising of the Avon, has been referred to Mr. Wolfe Barry, but his report has not yet been presented.

The Lower Thames has long been the subject of complaint, owing to the alleged insufficiency of depth of the navigable channel to the various docks on the river. In consequence, an important inquiry as to the condition of the Lower Thames for navigable purposes has been held during the past year by a Commission appointed by the Board of Trade under the powers of the Conservancy Act of the previous session. The shipowners had made allegations as to the shoaling of the channel and the necessity for dredging, and expressed a strong opinion that the depths and widths which the Thames Conservancy had adopted as a standard for their dredging operations were not sufficient. After holding several days' inquiry, the result arrived at was that the evidence as to the condition of the river was so conflicting, and the charts in evidence so untrustworthy, that it would be impossible for any satisfactory report to be made until the river has been surveyed. This was accordingly done during the summer, partly by the staff of the Admiralty, and partly by that of the Conservancy. The result of this survey shows that the increasing difficulties of navigation arise more from the increase in the draught of the steamers navigating the river than from any shoaling of the channels. In fact, the survey shows that the navigable channels of the Thames are quite 2ft. deeper than they were supposed to be, and that since the date of the last chart there has been a material improvement going on in the condition of the river. It does not seem to be a very creditable condition of affairs that in an important navigable waterway like the Thames the only existing official information that the Commissioners could obtain to assist them as to the navigable depths was from soundings obtained by a partial survey made in 1883 and published on the Admiralty Chart. The report of the Commissioners has not yet been made known.

With regard to the floods in the Upper Thames, a report has been issued by a Committee of the Conservancy which was appointed to investigate the charges made at numerous meetings held in the early part of the year throughout the district, to the effect that if the Conservators had exercised more activity in their control of the river, the effects of the great floods of November, 1894, might have been very considerably mitigated. In this report the Committee contend that they have no powers enabling them to carry out works for controlling or dealing with floods, and no funds to devote to any such purpose, their business being solely to maintain the navigation. They point out, however, that the works which have been carried out for the improvement of the navigation have materially aided in improving the discharging capacity of the waterways. The old and inefficient weirs have been replaced by those of more modern construction, provided with gates drawn up by suitable gearing, and having waterways considerably larger than the old weirs, the flood-discharging capacity of the new weirs being equivalent to a rainfall of 0·12in. in twenty-four hours in the upper part of the river, equal to 4500 millions of gallons at Teddington, or ten times the summer flow. More than £50,000 has been spent on dredging and deepening the channel during the last twenty years. The Committee further point out that houses and other buildings have been erected within the limits of what has always been the natural flood level of the river.

Floods, such as those of November, 1894, are very exceptional, and to provide relief from these would require works of great magnitude, the cost of which would be very severely felt in the district; while any systematic attempt at enlargement of the sectional area of the river, and the lowering the level of the water, would have to be approached with care, as such a proceeding might seriously affect the agricultural land adjacent to the river, by draining away much of the subsoil water. There are, however, works which could be carried out at a moderate cost, which would tend to mitigate the inconvenience caused by the frequent floods which now occur. As funds to carry out these can only be provided by rating the land and property, it is suggested that the local authorities and landowners, if they want relief, should apply to Parliament to constitute some representative authority, with power to levy rates and carry out works.

One notable event of the year has been the completion of the piers at the mouth of the Tyne, which have been in course of construction for the last forty years. No public ceremony has been inaugurated to celebrate this important and almost national work.

Although the traffic on the Manchester Ship Canal is a long way from reaching the amount on which the original estimates were based, yet it steadily continues to increase. The sea-going tonnage for ten months of this year amounts to 891,134; the first six months averaging 80,125 tons a month, and the last four 102,566 tons a month. Regular services have been established with Calcutta, Madras, and Colombo. Steamers have also come from China and Australia, and several cargoes of this season's cotton from America, and the quantity imported direct from Egypt shows that already a firm trade with this country has been established. Timber imports have increased, which shows that the building trades round Manchester are now largely supplied by vessels coming up the canal. The dried fruit trade from the Mediterranean, and Seville oranges used in the marmalade factories in Manchester, are now imported direct by means of the Canal. The receipts have reached a sufficient sum to cover the working expenses and cost of maintenance. Several outstanding difficulties have been settled during the past year, including the long-pending dispute with Warrington; and a decision was given in the law courts in favour of the company as to its liabilities with reference to the Upper Mersey. The London and North-Western, and Lancashire and Yorkshire Railway companies have been completing the works necessary to put those railways in direct communication with the canal, so that goods may be placed direct on the two systems at the docks.

In inland waterways there is very little progress to report. The decrease in the tolls, leading to a diminution of income, brought about by the Board of Trade at the instigation of the traders, appears to have checked the outlay of money in those canals in which the greatest disposition to move with the times has been shown. The Leeds and Liverpool Company is spending a considerable amount in making its waterway better for navigation, but the rate of improvement has been checked in order to await the issue of the large reduction which is expected in its income from the decreased rates at which it has now to carry goods. So also the Aire and Calder, although it obtained powers this session to make some improvements in the system at Leeds, appears to be waiting the course of events before proceeding with the canal, for which powers were obtained two or three years ago, for connecting the system with that of the

Sheffield and South Yorkshire. This latter company, which after a gallant struggle succeeded in wresting the canal out of the hands of the Manchester, Sheffield, and Lincolnshire Railway Company, has succeeded in raising sufficient money to pay the railway company the amount finally settled on for the purchase of the undertaking. The railway company, however, appears to have got the best of the bargain, for not only has it obtained a large sum in cash, but also such a controlling influence on the directorate as to paralyse any attempt at improving the canal so as to make it an independent competing means of transport. At any rate, although six years have elapsed since the Act was obtained incorporating the new company, no works of any importance have yet been carried out.

The river Ouse, which connects Lynn with Bedford, has for a very long period been used as a canal from above Earith, but the locks and other works had been allowed to go to ruin. The navigation was purchased some time ago by Mr. Simpson, who at once commenced to put the works in repair and dredge the channel, and during the past year this has been completed, and steam barges are now able to trade between Lynn Dock and Huntingdon, St. Neots, and Bedford—a distance of 73 miles. The scheme for connecting this waterway by a short cut with the Grand Junction Canal has not been again revived.

One important step in the revival of inland water communication has been accomplished by the Act passed this session for forming a public trust for taking over the Thames and Severn Canal, which extends from the Thames at Lechlade to the Stroudwater Navigation, and thence to the Severn below Gloucester. The Trust consists of representatives of the navigations amalgamated, of the Gloucester and Sharpness Dock Company, Birmingham Canal Navigations, Wilts and Berks Canal, and the County Councils of Gloucester, Wilts, and Berks. A portion of this canal had practically become derelict, and the owners proposed to close it. The new Trust are taking steps to have the canal put in working order, and there is a prospect of this leading to further developments in the same direction.

The proposed purchase of the three short canals which connect the Grand Junction with Birmingham, and for which Parliamentary powers were to be obtained. has fallen through for the present.

The improvements which have recently been carried out in the Belgian and German ports point to the conclusion that the commercial rivalry between Great Britain and those countries is becoming more and more intense. Already there has been a rapid development of the German mercantile marine. The improvements of the harbour at Hamburg, which have been effected at a cost of £400,000, allow vessels of the first-class now to enter that port, the twin-screw steamer Palatia, drawing 26ft., having navigated the Elbe just recently. Cuxhaven is having extensive works carried out, with the object of making it a port of call for Transatlantic boats. The Weser has been trained and deepened between Bremen and Bremerhaven, so as to allow vessels drawing 16½ft. to reach the former place, and a deep and spacious harbour made at the latter. Already the tonnage of sea-going vessels entering the port has increased from 94,000 to 641,000 tons. The river traffic has also increased in greater proportion. The new basin at Bremerhaven is being enlarged to receive vessels drawing 32ft., and this work is expected to occupy the greater part of next year. As regards the Baltic ports, Lubeck is to be connected with the Elbe by the Elbe-Trave Canal; the fairway between Stettin and Swinemunde is to be dredged out so as to give a depth of 22½ft.; the navigable channel between Konigsberg and Pillau is also undergoing improvement. Russia is constructing a new harbour at the mouth of the Neva. The completion of the Dortmund-Ems Canal will open a market in the Baltic for the Westphalian coalfields, which may seriously affect the export of that mineral from this country.

The most notable event of the year, however, was the opening of the North Sea and Baltic Canal, or, as it has been officially named, the "Kaiser Wilhelm Canal," and, although there has been considerable traffic through the canal, it has not come up to the expectations of the authorities, especially the foreign trade, three-fourths of the vessels using the canal being engaged in trading to and from Hamburg.

The scheme for training a channel through the estuary of the Seine, and for deepening the approaches and improving the accommodation at Havre, and also for making a deeper lock, after having been before the French Legislature for some years, finally passed both Houses, and the funds necessary for carrying out the works voted in the early part of this year. An account of the proposed works will be found in THE ENGINEER of July 26th.

Belgium has also during the year made an important advance in the improvement of her internal navigation by voting the necessary credits for opening a ship canal to Brussels by way of the Scheldt and the Rupel, and the enlargement of Willebroeck Canal; and also in her sea communication by making a commencement with the proposed new port at Heyst, which is to be connected with Bruges by a ship canal. The reduction of the port charges at Antwerp will further tend to attract trade there.

The improvement of the communication between this country and the Continent has made progress during the year. On this side the new pier in Dover Harbour has made considerable advance, and preparations are being made for commencing the construction of the mail packet water station which will involve the reclamation of about six acres from the harbour at the eastern corner of the Admiralty Pier. On the other side the widening of Calais Harbour has been nearly finished, the new pier on the east side having been completed to above high water; but the process of removing the old pier and deepening the extra width proceeds but slowly. It has also been decided to carry out further improvements at Ostend.

In Holland, a new deep-water lock has been constructed at the entrance of the Amsterdam Ship Canal at Ymuideu.

The proposal for forming the Canal des deux Mers between the Bay of Biscay and the Mediterranean has, during the last year, been again revived, and its claim prominently pushed forward by those having a local interest in it, and it has also been frequently favourably noticed by those who have not carefully considered its possibilities; but by responsible French officials and others who have paid much attention to the subject, the canal is considered as outside the range of practical possibilities. An account of the scheme will be found in THE ENGINEER of November 9th, 1894.

Another French canal scheme which has been revived during the year is that for connecting Marseilles with the Rhone, which is estimated to cost 3¼ millions, but it has not yet assumed any practical shape.

The immense traffic which passes along the Great Lakes of America has been afforded further facilities during the past year by the completion of the new lock and canal on the Canadian side of the Sault St. Marie Falls, and which it is expected will play an important part in attracting traffic through the Canadian Territory, and down the St. Lawrence. The new lock, by which the 18ft. fall of the Sault St. Marie is overcome, is capable of taking the largest vessels which navigate the lakes, being 900ft. long and 60ft. wide, with a depth of 20ft. on the sills. A canal has been cut across the island, about three-quarters of a mile in length. Beyond its large size as a canal lock, the distinguishing feature about it is the adaptation of electricity for the purpose of working the machines for opening and closing the gates. Power is acquired from two 45in. turbines, giving off 310-horse power. One of these is used for running the generators and the other the arc light dynamos which light the lock and its approaches.

A further development of electricity has been made on the Erie Canal, where an experiment has been made of hauling the canal boats by means of an attachment to overhead conductors, on the trolley system.

All hopes of completing the Panama Canal are not yet abandoned. A large staff of men are engaged on the works in keeping up the machinery and in carrying out experimental and preliminary works previous to active measures being taken to complete the canal if the necessary capital can be raised. Sir H. Tyler, who visited the country a few months ago, expressed the opinion that the completion of the canal is feasible, and by no means a hopeless project, either from an engineering or financial point of view. Mr. Colquhoun, who also has visited the canal, does not share in this sanguine view of the matter. According to Sir H. Tyler's account, all that is required is six years of time and £20,000,000 of money. He states that he found nineteen miles of the canal already completed, and that where the bed of the canal has been excavated it has only filled up to the extent of about 3½ft. since the works were stopped four years ago. The banks have not suffered materially, in consequence of the rapid growth of vegetation. The machinery is being carefully preserved, and there is sufficient of it on the ground to finish the canal. The number of men at work at the time of his visit was 1500, and about half as many more were expected shortly to arrive, and he was informed that it was intended to increase the number to 6000. The report of the engineer of the new company recently issued states that the surveys now being carried on demonstrate the feasibility of the construction of a dam for the purpose of forming a lake 200ft. above the level of the sea sufficient to supply the canal with water at all seasons of the year. The highest level of the canal has now been fixed at 131ft. above the level of the sea, and this is to be reached by five locks with a rise of about 33ft. each. It is proposed at first to cut the canal only 50ft. wide, and then let in the water from the lake, which will permit of dredgers being used to compete the excavation. All this, however, will depend upon the subscription of the necessary capital.

With regard to the Nicaragua Canal, very little has been done to forward matters during the past year. The commission appointed by the United States Government to report as to the feasibility of the canal and its cost, has recently reported that to complete the canal will require a sum of nearly 27 millions of pounds, or about double the company's estimate. They further express the opinion that to proceed on the information at present available would be impracticable, and that before any trustworthy opinion can be formed further surveys are necessary, which will require eighteen months of time and cost £70,000. In the meantime the works which have been already carried out are deteriorating, especially the dredged channel in Greytown Harbour, which is shoaling by sand drifts.

Ths Corinth Canal does not appear to be growing in favour, the traffic increasing very slowly. Several land-slips have occurred, by which traffic has been hindered. It is reported that the sides of the cutting in places are slowly disintegrating and crumbling away. The receipts barely cover the working expenses.

ELECTRICAL ENGINEERING.

ON looking back over the past year and comparing it with the year 1894, we are able to note a decided improvement in business, and the prospects for the present year are certainly brighter than those at the beginning of last year. The greatest development of the application of electric energy in Great Britain is, without doubt, in the business of supply of current for the purpose of electric lighting. Looking broadly at the subject, it must strike the observer that the growth in the supply of the electric current resembles very closely the growth of the great gas industry. Gas is now supplied from very large producing centres, usually outside the towns, or at least away from the neighbourhoods occupied by the wealthier classes, and at some distance from valuable commercial property. These great centres have gradually taken the place of the earlier and smaller producing centres. At present there is only one great producing centre for the supply of electricity which fulfils the required conditions of easy access for fuel, space for increase of size, and distance from valuable property, and that is the Deptford station. The bulk of the other stations, especially those supplying the metropolis, are situated in close proximity to valuable property, and are continually harassed by injunctions or by the fear of injunctions. The present system is at best but a temporary arrangement which must be done away with. Signs are not wanting of the approach of change, as current is even now being supplied to certain stations from others more favourably situated for the work. Machinery is even now standing idle while current is supplied from a distance.

Perhaps the most gratifying sign of the times is the solid basis upon which the supply of current is now placed. It is seen to be a financial success, and municipalities on all sides are taking up the work of public supply, and find that they can earn good profits and supply electricity at a very reasonable rate. The growth of demand is in new cases very rapid, and the increase of the capacity of the generating plant has become one of the most important branches for the builder of electric light machinery to follow.

There is, of course, no one rule which will apply to the design of all stations, and it is interesting to note the various forms which are taken by supply centres for different areas. Edinburgh, for instance, is using both the alternating and direct current for different districts, and the demand for light has far exceeded expectations. Glasgow is now well lighted; Halifax is using the high-pressure alternating system, with transformers in sub-stations; Nottingham and Dewsbury the low tension direct three-wire system, with accumulators; Great Yarmouth and Stafford have also municipal stations, all opened in the past year. In some cases the gas-producing station adjoins the new electric light station. Of this the town of Blackburn is an example; while at Leicester the new station was actually designed and laid down by the borough gas engineer, who has produced one of the finest stations in the country, having admittedly followed the practice of some of the continental engineers in erecting a fine building as well as installing good plant.

Wolverhampton has chosen the high-tension direct system of supply, and forms the fourth example in this country, the others being the Chelsea, the Crystal Palace, and Oxford Electricity Supply Companies. Wolverhampton, however, has made a step in advance, and uses a potential of 2000 volts instead of only 1000 volts, as is the case at Oxford. Portsmouth has almost created a record, for the station paid well even during the first six months, and is stated to be producing electricity at 2·3d. per unit, cost price; it is, as our readers will be aware, fitted with slow-speed alternators and rectifiers. With respect to the type of motors in use for driving the dynamos, the internal combustion engine is decidedly coming into greater favour. and the size of gas engines is steadily increasing. At Belfast tandem gas engines alone are in use, and appear to be very economical; and doubtless where both gas and electric supplies are in the hands of municipal authorities, this method of driving will come into still greater use. As the size of the units increases—for it must do so—we shall see whether the gas engine using either illuminating or producer gas will be able to increase in size, and to give results equal to those obtained by the use of steam.

The time has now arrived in many places when the capacities of the stations for supply are by no means equal to the present demands or to that which will be made in the near future, and engineers are looking for some means of increasing the capacity without great expense. In Bradford the question has been solved by the use of lamps of 230 volts, so doubling at one stroke the capacity of the mains. Difficulty was at first found in obtaining such lamps; but a satisfactory type has now been produced, and it seems very probable that this year we shall see a greatly increased use of distribution at 400 volts on the three-wire system. One of the difficulties at present in the way, however, is the jerry system of wiring often adopted and the low class fittings often used; these may be passable and not absolutely dangerous with 100 volts, while they might be distinctly unsatisfactory, and even the cause of fires, if double that potential were employed. More stringent rules will have to be followed if the proposed changes are carried out on a large scale. The lamps have been proved to have a life of 3000 hours in some cases, and although the average life would doubtless be considerably below this figure, it is a clear proof that manufacturers are well able to supply lamps of good quality. Such a change will doubtless lead to the use of special supply mains for arc lighting. The destruction of dust as an auxiliary means of supplying steam is also coming to the front. St. Pancras has installed a number of cells; but, perhaps, Shoreditch is the best example of the grouping of municipal works close together. Here the electric lighting station, with its dust destructors, is upon a site adjoining that reserved for the public baths and wash-houses and also the public library. The electric station will supply the whole of the steam, hot water and light required in the other two establishments, thus obviating altogether the necessity for boiler power in the baths establishment. Possibly in the near future we may find a case in this country where street electric tramways are owned by public bodies, and actuated from the large joint power and light station. It has become essential to success to use every means of promoting economy in production, and for this purpose superheating is coming into favour, and there are now in use several different methods of dealing with the steam. The large quantities of water required also cause great expense when the supply is bought from a water company, and this is leading to the sinking of numerous wells in generating stations, and an important saving in cost.

The electric light has, of course, very powerful rivals in the Welsbach and other forms of incandescent gas lights; and as the price of the fittings for the latter is diminishing, it becomes more than ever important to effect a saving in the cost of generating electricity wherever possible. A reserve of energy is essential to economy in working, and thermal storage is being put into use as a rival to the better known system of electrical storage, and may in some cases effect the desired result in a more economical manner. It is probable that in certain cases the use of producer gas, and the sale of the bye-products, would still further reduce the cost of the unit, and in this particular line it appears that the continental engineers are somewhat in advance of us.

The increase of the day load factor is still the great aim of all central station engineers, and the advantages of electric cooking and heating are being assiduously pressed upon the attention of the public. Already one theatre is heated by electrical radiators, and the use of electric cooking apparatus is steadily advancing. The public—and, indeed, many engineers—seem still somewhat incredulous as to the pecuniary advantages claimed for the system by its advocates; but its superior cleanliness and obvious absence from products of combustion will, we are sure, obtain for it a very extended use wherever public supply is at hand and cost a secondary consideration. One of the chief proofs that we have not yet found a perfect system of constructing the underground network of supply is the numerous street explosions which still take place. Doubtless these are for the most part due to the leakage of illuminating gas into the electric conduits; but the matter has occupied the attention of the Board of Trade on many occasions, and no very satisfactory means of coping with the evil has yet been discovered. Lately one or two serious fires have occurred at electric light stations, and one at least emphasises the disadvantage of using wood for important switchboards. The British practice on this point we consider is far ahead of the usual practice in the United States.

Passing now to the question of electric traction, we find that in London we are likely soon to be provided with several new underground railways of a type similar to the City and South London Railway. One of the most noteworthy points abroad is the fact that the Chicago elevated railroad, which many of our readers travelled upon during the Exhibition year, has entirely abandoned the use of steam, and has installed an electric plant instead; this result is due to the obvious economy obtained in the working of the Intramural Railway in the Exhibition grounds. Electric locomotives appear to be growing in favour; the first, constructed by the Heilmann Company, was not entirely satisfactory, and was considered by its makers as quite experimental, but two new ones will be in use this year on the Western of France Railway, and should give results of interest to all railway engineers. Experiments in the same direction are being made elsewhere in France, and also in Belgium, while in the United States an electric locomotive is now hauling both freight and passenger trains through a tunnel on the Baltimore and Ohio Railroad. No exact tests have yet been published relating to any of these novel engines, but doubtless in the course of the present year they will become available.

The state of agriculture in this country has called for careful consideration on the part of the Government, and among other things feeder lines of railway have been suggested. In this connection it is of interest to note the fact that electric traction is being used on the Nantasket Beach branch of the Old Colony Railroad Company, Mass., U.S.A., and we believe that in many cases light railways worked by electricity will find favour for agricultural districts ere long. Looking at the systems of street electric railways now in use, it appears that the overhead wire is the only one which has yet been found to pay. Reports from Birmingham state that the accumulator system is a dead failure financially, and is a millstone about the neck of the company. On the other hand, the St. Denis-Madeleine line in Paris appears to be satisfied with its battery system. In the latter case, however, it is very improbable that permission would be accorded for the use of an overhead wire.

Both Dublin and Bristol are using the aërial conductor, and the splendid series of illustrations of foreign practice, which have recently appeared, prove to persons who have had no opportunity of personal inspection that the overhead wire can be made an ornament, and not an eyesore, even in streets of good architecture. The prejudice against such wires will, perhaps, gradually disappear in this country, and the railways in South Staffordshire, the Isle of Man, Leeds, and elsewhere, prove that the system is well adapted to the requirements of the public. The well-arranged system in many German cities must certainly lead us to think that we are very much behind on this point. An electro-magnetic system used in Washington, D.C., has recently been acquired by the Westinghouse Company, and some such system may possibly meet the requirements of crowded thoroughfares in large cities, where the overhead wire cannot be used.

In dynamo construction improvements have been made in the method of winding direct current armatures, which have been highly spoken of by some of the chief dynamo builders, and are known as the regenerative type; hinged pole pieces have also been introduced. At Puteaux, near Paris, a large installation has been put down of fly-wheel alternators driven direct by slow-speed engines, and the details of the construction are much improved; while at Deptford a 1000-kilowatt machine has just been erected which has probably the largest output of any machine yet built. The Niagara power plant is approaching completion, and a somewhat heated controversy has been raised as to the authorship of the design, which is probably due to no one single individual.

As yet no very satisfactory motors for single-phase alternating currents which will start with the load on are available, and the best type appears to be procurable only on the Continent. At present there are motors used for driving ventilating fans supplied with current from the alternating circuits in London; but experience has shown that a motor nominally of about double the power of the work required must be put down if satisfactory results are to be obtained. The demand for high-speed engines for direct driving still increases, and has caused the production of one new type during the past year which bids fair to give very good results, as experience with an older type has been available as the groundwork of the new design.

Inventors still appear to consider that there is a field for the application of primary batteries for the production of light and power; the past year has seen a renewed attempt to use zinc in such a battery, and employ it for launch work. We fear that although zinc has been proved over and over again to be too expensive a fuel, that money will still be spent on the attempt to use it as a rival for coal; while abroad a new type of battery to produce electricity direct from combustion has met with only qualified success.

Water power plants are not very common in Great Britain, but a project has during the past year been brought forward to use a celebrated fall in Scotland for the production of power to be used in the manufacture of aluminium. The present year will probably see the question decided as to whether the falls are to be reserved as a natural piece of scenery or turned to commercial uses. In Germany the city of Munich has made use of part of the great water power of the river Isar, and will probably do so to a still larger extent in the near future. The great Niagara scheme can hardly be said to be a feature of last year's work, although, of course, its completion has been advanced.

Electro-metallurgy has made considerable progress. Perhaps one of the most important discoveries was that of the production of carbide of calcium while the attempt was being made unsuccessfully to produce metallic calcium, and this has resulted in the production of acetylene at a price far below that previously possible. The present year will doubtless see this gas used as a competitor in public favour with the electric light, or employed as a means of enriching coal gas for illuminating purposes. At present it seems, however, that a natural water power is almost essential for the economical working of the process of production.

Ozone produced electrically is rapidly coming into practical use as a very powerful bleaching agent, and work in Germany appears to prove that it will shortly become a commercial success.

The process of electro-zincing seems to be finding favour in place of galvanising, especially for the tubes of boilers for marine work, and the adhesion of the zinc to the surface of the iron appears far superior to that obtained by the older process. Cyanide of potassium and potassium zincate are also the principal factors in recent electrical processes. Electric welding on the Thomson-Houston process does not appear to increase so much in public favour in this country as in the United States, but a new process has lately been invented in Germany by which the electric arc is treated as a blow-pipe flame, by means of an electro-magnet, which is likely to give very good results, both for welding and soldering of many metals. The advantage of the latter process is that the portions treated are not damaged by operations in an open fire, as is, of course, the case in ordinary welding operations.

Road vehicles propelled by power will doubtless become very common in a few years; but whether it will be found possible to apply electric energy to this purpose economically is as yet somewhat uncertain. In the Paris-Bordeaux race for horseless carriages, an electric vehicle took part and performed the journey safely; but it is very doubtful whether the use of accumulators will be found satisfactory, and they will have a powerful competitor in the gasoline motor, which now appears to hold the first place in this particular branch of engineering.

Electricity has been recently applied in France to an improved form of submarine boat, designed for the purpose of discharging torpedoes; and in the United States, as well as in Great Britain, ingenious applications of the electric motor have been made to the rudders of small boats. The latter type of apparatus being easily detachable, seems to have a future before it for light pleasure boats.

In maritime affairs the application of electrical communication between lightships and shore has already made some progress; but a perfectly satisfactory solution of the problem still remains to be found. The North Sea Canal, opened last year, is now lighted along its banks by electricity; and the use of the light has become quite general for the passage of the Suez Canal.

A new type of instrument for the purpose of transmitting photographs to a distance and there reproducing them by line engraving suitable for printing has been brought out by an American, and the published results appear to show that the process is very satisfactory. Organs are now being fitted with electric apparatus of improved type, and a process of marking paper and fabrics by means of the electric current has been invented and put into use. Experiments on high frequency currents have been carried on by Tesla, Toepler, and others, and the electric discharge has been made a special study by Lord Armstrong.

Train lighting by electricity does not appear to make much progress; in fact, it has been discarded after fair trial by several of the large railway companies. It is therefore somewhat surprising to see the London, Tilbury, and Southend Railway taking the matter up anew, and we shall look for the results in the present year.

Electricity appears to be slowly taking up a proper place in medical treatment, but quackery is as yet by no means extinct, and the subject still requires more accurate experiment before its precise value as a curative agency can be known.

SANITARY ENGINEERING.

A remarkable report on the main drainage of the metropolis was very recently laid before the County Council by the Committee having the oversight of that work. The Committee began by saying they had to call "the serious attention" of the Council to the present state of the main drainage of London on the north side of the Thames, and to the necessity for works of a somewhat extensive character with a view to rendering the system more complete and effective for the purposes which it is required to fulfil. The chief engineer to the Council, Mr. A. R. Binnie, pointed out to the Committee that the population of London had increased by about a million since the main drainage system was designed, and that the drainage of certain outlying places had been taken in. From the figures which related to the subject, the chief engineer argued that the whole main drainage system was gradually becoming insufficient for its work. Since March, 1889, about twenty-three miles of new brick sewers had been constructed, as well as ninety-four miles of pipe sewers, and during the same period there had been an increase of 30,000 houses in London. The chief engineer, reviewing all the facts of the case, declared himself more strongly impressed than ever as to the necessity of proceeding with certain works. If this were not done, he feared that "the main drainage system would fall into disrepute." The Committee having carefully considered the subject, felt compelled to recommend to the Council that works of an extensive character should be undertaken to improve the main drainage on the north side of the Thames. The total expenditure involved was £745,000, to be spread over a period of four years. Notwithstanding the earnest representations of the engineer and the Committee, an amendment was moved by Mr. McDougall, that the general enlargement of the main drainage system was "not now necessary, but that local floodings need immediate attention." Mr. McDougall stated that the Council had already expended £165,000 on improving the main drainage north of the Thames, and "he did not believe further heavy expenditure was necessary." Adding this £165,000 to the £745,000 for the works recommended by the Committee, we get a total of £910,000. But in February, 1891, a joint report, presented by Sir Benjamin Baker and Mr. Binnie, proposed an outlay of £920,000 for drainage works north of the Thames. Of this amount, it would appear that £55,000 had been applied in the manner then proposed. Despite the strong arguments of the Committee, backed by professional opinion, Mr. McDougall's amendment was carried by a large majority. The decision is one to be wondered at, and has the appearance of postponing the evil day. Sir Arthur Arnold has stated that if the main drainage system of London is to be made efficient, an expenditure of £2,250,000 must be at once incurred.

A very valuable series of experiments on the purification of sewage has been carried out by Mr. Dibdin, the chemist to the London County Council. These experiments have already been described in our columns, and have the great practical result of showing that "the necessity for costly farms" in order to purify the sewage of towns no longer exists. The area for the treatment of the whole of the metropolitan sewage is reduced to 180 acres, or even as little as 120. The plan is one of scientific filtration, based on biological principles. The mode in which Mr. Dibdin deals with the sewage at the metropolitan outfalls has had a marked effect in improving the condition of the river. Of course the filtration process is preceded by the abstraction of the sludge, of which 2,000,000 tons are carried away annually to the German Ocean.

WATER SUPPLY.

BOTH with respect to the incidents of the past year, and the prospect of that on which we are now entering, the chief interest of the water supply question has its centre in the metropolis. To provide an adequate supply for a present population of five millions and a-half, apparently destined to increase to rather more than double that number in forty years, is a problem of vast importance. In 1894 the daily supply furnished by the eight metropolitan water companies exceeded an average of 189 million gallons, and latterly the quantity has been more than 200 million gallons. According to such data, a daily supply exceeding 400 million gallons will have to be provided by the year 1936, a date which cannot be considered so very remote. From time to time during this range of years, from whatever source the supply is taken, proportionate additions must be made to the daily volume, and works will have to be commenced in anticipation of the coming want. Of the danger of any delay in this respect a striking example was afforded during the past summer. In 1893 the East London Company brought in a Bill asking for power to raise £500,000 to be expended in the enlargement of their waterworks. The London County Council, by their representatives, urged that there was no need for any such enlargement, and the Bill was rejected. In 1894 the company brought in another Bill to the same effect, and this was carried. The works were commenced in the most prompt and energetic manner, but came a year too late to save East London from the disastrous effects of the drought which took place last summer. A Government inquiry, which ensued, into the cause of the failure in the supply was seemingly almost superfluous, unless it were to test Mr. Binnie's theory as to the existence of broken pipes, allowing a great part of the water pumped into the district to escape underground. But it is scarcely possible to avoid the conclusion that the lack of adequate reservoirs was at the root of the mischief, and that the great lesson to be learned is one which shows the peril of tampering with the water supply of a great city. The reservoirs of the East London Company were able to store a supply for a greater number of days than those of any other company, but they had not the assistance of a great natural reservoir like the Thames, except that it might draw ten million gallons per day from that source. Even with a big river at its back, any company must needs have filter-beds in proportion, and it is not desirable to take the river water when unusually turbid from the effect of floods. Hence there is a need in every instance for works proportionate to the population, and the East London Company had to provide for a larger population than any other company, while the number of "services" was greatly in excess. This company had the further misfortune of getting much of its supply frozen up through the intense frost of the previous winter. Other companies suffered more or less from the same cause, and there was great complaint throughout London that the mains were laid at an insufficient depth. In this case also a Government inquiry was ordered. But both with regard to the frost and the drought, serious inconvenience resulted in some of the country towns as well as in London; neither could it be said that the municipal authorities managed any better than the companies.

Of the eight Water Bills promoted by the London County Council, for the transfer to that body of the undertakings of tha Metropolitan Water Companies, two passed a second reading in the House of Commons and were referred to a Hybrid Committee, which was on the point of completing its labours when arrested by the dissolution of Parliament. Steps were taken by the County Council to have the whole of the eight Bills suspended, so that they might be revived in the coming session. But in October a report was presented by the Council's Parliamentary Committee, recommending that the Government should be asked to deal with the question of the Metropolitan water supply, or else to appoint a Royal Commission for the purpose. On this an amendment was moved by Mr. J. Stuart, that the Council should proceed with the Purchase Bills; that is to say, with the eight Bills for the transfer of the undertakings. This amendment was negatived by a majority of one, and so the entire project for buying up the water companies fell to the ground. A week later a resolution was adopted, calling upon the Parliamentary Committee to report as to the terms on which the Government should be asked to legislate with reference to the question of the London water supply. In accordance with this request the Committee subsequently recommended that her Majesty's Government should be invited to constitute by Act of Parliament a public authority for the water area supplied by the present companies, such authority to have power to negotiate for the purchase of the existing undertakings. This proposal was rejected, an amendment being adopted by which the Government were to be asked whether they would promote or assist legislation on certain lines, the fundamental principle being that the entire control of the water supply within the County of London should be in the hands of the County Council in conjunction with the City Corporation, the supply in the respective areas outside the county of London to be subject to the local authorities. In addition, the Water Committee were authorised to initiate negotiations with the water companies for the purchase of their undertakings.

As it is not very likely that the Government will take up the *rôle* assigned to them by the County Council, nor yet that the negotiations with the companies will have any practical result, the metropolitan water question will come before Parliament in the approaching session in the shape of certain Bills promoted by the companies, providing on the whole a very large amount of capital. The New River Company proposes the construction of new works, together with extensive improvements generally, and seeks power to raise £1,500,000. The Southwark and Vauxhall Company has a Bill authorising new works on a considerable scale at Walton-on-Thames, fresh capital to be raised to the extent of £750,000. But the most striking scheme of all, though only associated with the raising of £1,000,000 of capital, is that which is embodied in a Bill promoted by the Grand Junction, West Middlesex, and New River Companies. The plan is for the construction of extensive storage reservoirs in the neighbourhood of Staines, in part fulfilment of the scheme which was laid before the late Royal Commission on Metropolitan Water Supply by Mr. Walter Hunter and the late Mr. Alexander Fraser. In their report the Commissioners spoke approvingly of this project, designed when complete to furnish a supply equal to the demand at the end of forty years. The present project has reference to a shorter period—some ten years or more. The supply will be drawn from the Thames, at a point a little above the town of Staines. There is a Bill promoted by the Chelsea Company, for the construction of new works at Molesey and Surbiton, and the raising of £50,000 of capital, which stands over from the past session. A Bill promoted by the Lambeth Company, requiring £500,000 additional capital, is in the same position. Whether these Bills will be proceeded with is at present uncertain. There is one Bill emanating from the London County Council, but it falls short of anything in the shape of purchase, transfer, or a new supply. It is simply a measure requiring the East London Company to give the constant supply at such a pressure as will force the water to the top storey of the highest houses in that part of the district which is within the County of London. Penalties are prescribed in the event of default. There is a Bill of which notice has been given by some of the local authorities of the county of Kent, proposing the creation of a Kent Water Board, which is to buy up the works of the Kent Company, and the outlying portion of the Lambeth waterworks. But it would appear that the Bill will be dropped, in the absence of any attempt on the part of the London County Council to purchase the undertakings of the metropolitan water companies. Looming in the distance there is a scheme which overtops everything of a cognate nature. The London County Council are not yet prepared with a Bill to carry out the project devised by their chief engineer, Mr. A. R. Binnie, for bringing a supply of water to London from Wales. But the work of preparation is going on, and assistant engineers for completing the necessary surveys have been engaged for twelve months ending next Christmas. It appears not unlikely that notice of the Bill will be given next November. A certain amount of opposition to the project has been manifested in some parts of South Wales, especially in Glamorganshire; but, as recently shown in our columns, Wales has water enough and to spare, and need stand in no fear even if London went so far from its own watershed in search of a supply.

The progress of the water supply in the provinces has presented no very striking feature during the past year. In October the Glasgow authorities accepted a tender for the construction of the last section of the new aqueduct to Loch Katrine. When completed the new works will enable Glasgow to draw from Loch Katrine 100,000,000 gallons per day, in place of 42,000,000 gallons per day now drawn by the city. The appropriation of distant sources of water supply by large cities is giving rise to considerable discussion. As far back as 1869, the Royal Commission of which the Duke of Richmond was chairman, laid down the principle that no town or district should be allowed to appropriate a source of supply which naturally and geographically belonged to a town or district nearer to such source, unless under special circumstances which would justify the appropriation. It was also considered that when any town or district was supplied by a line of conduit from a distance, provision ought to be made for the supply of all places along such line. Some illustration of the need for observing the principles thus enunciated occurred in the recent session of Parliament. The Barnsley Corporation had a Bill for the carrying out of new works of water supply, and for power to direct and use the water of certain tributaries of the Little Don, also known as the Porter River. The Corporation of Sheffield put in a claim for some portion of the supply. Rotherham and certain other towns were interested, and there was a quarrel as to the possession of the drainage area. The House of Lords passed the Bill of the Barnsley Corporation, on the ground that Barnsley was in the valley of the Don, and had a right to a share in the water, whatever demands Sheffield or any other town might make. But the Bill was impeded owing to the dissolution of Parliament, and failed to pass the Commons. It was in consequence suspended. The Corporation of Sheffield have a Water Bill for the coming session, in which, as in the case of the Barnsley scheme, power is sought to deal with the waters of the Little Don. In addition to the supply taken by Sheffield, provision is to be made for supplying water to the Corporations of Barnsley, Rotherham, and Doncaster. There are several other Water Bills to come before Parliament affecting various localities, including Birmingham, Portsmouth, Chester, Derby, Brighton, Eastbourne, Reigate, and Huddersfield.

GAS SUPPLY.

Towards the middle of the year, the report of the Board of Trade Committee on standards for testing the illuminating power of coal gas made its appearance. The Committee recommended that the pentane-air flame furnished by a Dibdin Argand burner, having the form and dimensions set forth in the appendix to their report, and used in the manner there defined, should be accepted as giving the light of ten standard candles, and that this flame should be authorised and prescribed for official use in testing the illuminating power of the gas supplied by the London Companies. As far back as 1879 a Committee appointed by the Board of Trade had presented a report condemnatory of the sperm candle as a means for measuring the intensity of light; but the difficulty of finding a better standard had the effect of delaying a satisfactory conclusion for many years. Now at last the proper method seemed to be arrived at, though this was only adopting what had been proposed by Mr. Dibdin as far back as 1886. It remained for the Board of Trade to introduce a Bill to legalise and enforce the new standard. But the dissolution of Parliament and the change of Government threw back the course of legislation, and the Bill failed to appear. The County Council have lately been taking the matter up afresh, urging the Board of Trade to promote the required Bill in the coming session, so as to give effect to the recommendations of the Standards of Light Committee. The Board of Trade have not hitherto shown themselves very ready to move in the matter, and apparently would not object to see the enterprise undertaken by the County Council. But the latter have expressed an idea that there would be a greater probability of success if the Bill were introduced by the Board of Trade than by themselves. "The agreement of all parties" is desired, and as the mode of applying the standard involves some particular points, this "agreement" may not be so near at hand as could be desired. But it is high time that the notorious defects of the sperm candle were made to give place to a really scientific and accurate mode of measurement.

The consumption of gas in London, which showed a decline in 1892 and 1893, revived in 1894 with an increase of $1\frac{3}{4}$ per cent. There is more than one cause at work to affect the rate of consumption. Foremost we must place the electric light. The report of the Medical Officer of Health for the City of London shows that a year ago there were, in the civic area, nearly 3000 private consumers of electricity, using upwards of 136,000 incandescent lamps. Nearly 500 electric lamps had been placed in the public streets, displacing above 1300 gas lamps. It is impossible that a change of this magnitude can take place without some effect being produced on the quantity of gas sold by the gas companies. There are no indications in London that the popularity of the electric light is falling off. Its use is clearly extending, and may be expected to undergo constant development. But the marvellous growth of London has to be taken into account, and this gives the gas companies so wide a field that they can allow a considerable amount of competition without suffering sensible loss. The Gas Light and Coke Company, of whose district the City forms part, shows an increase of gas sold during the June half year of 1895 as compared with the corresponding period of 1894. Another matter for consideration is the economy effected by the use of improved modes of consuming gas for illuminating purposes. Incandescent gas burners produce a snowy, steady flame, and greatly reduce the consumption of gas in proportion to the amount of light. The result to the gas company is not altogether satisfactory, except that gas being found both cheaper and brighter than formerly, there is the less disposition to have it supplanted by the electric light. An element which tells directly in favour of the companies is the augmented use of gas for heating purposes, and also as furnishing a convenient motive power. The commercial production of acetylene is a fact of much interest, rendering this powerful illuminant available for the enrichment of coal gas, though it is held by many parties as secondary to the question of cheap gas.

Some startling accidents have occurred, owing to the blowing up of electric-lighting boxes under the streets. Early in the year Major Cardew, the electrical adviser of the Board of Trade, discovered that these were due to a deposit of the metal sodium on some of the insulators. Gas having intruded into the box, and water having attacked the sodium, the conditions of an explosion were set up, and the natural effect followed. The cause which led to the blowing up of the paving stones having been discovered, it was comparatively easy to prescribe the remedies. A yet more astonishing instance of the explosive force of gas mixed with atmospheric air was afforded in the neighbourhood of the Strand, where a leakage from a fractured gas main led to a disastrous explosion, wrecking a couple of houses, and causing the death of a gallant member of the Fire Brigade, as well as injury to other persons. Another form of mischief consists in the poisonous properties of coal gas, of which a painful instance has lately been afforded in the death of the Rev. W. E. Hurndall.

CHEMISTRY.

1895 must be reckoned a noteworthy year as far as the chemical world is concerned. Both scientifically and industrially great activity has been displayed, and substantial progress has been made. Nor is there any sign that a lull is about to occur. Should 1896 fail to produce anything absolutely original, it is at least certain that much excellent and necessary work will be done in developing and reducing to order those ideas in which the previous year has been fruitful.

Avoiding the futile and mischievous method of attempting to separate pure physical knowledge from those applications to the useful arts which are its immediate or ultimate outcome, we may nevertheless choose for the beginning of our survey a discovery from which no industrial advantage has yet emanated, and from which none is, as far as our present ignorance extends, likely to accrue. When the detection of argon as a constituent of common air was announced in the autumn of 1894, few supposed that the consequences of Lord Rayleigh's masterly observation of a small but constant anomaly would be as far reaching as they have since proved it to be. Not only has the isolation of this substance shaken to its foundations a chemical hypothesis—the periodic law—hitherto justified in every particular, but it has also led, in the hands of Professor Ramsay, to the discovery of another body—helium, and to the anticipation that a series of elements, resembling each other rather than any better known form of matter, may exist for the delight of the investigator and the tribulation of the chemical gerund-grinder. As to its properties, argon is as sphinx-like as ever; even in its preparation an abnormality occurs; nitrogen, which is at first readily removed from it by the action of heated magnesium, can finally only be eliminated with difficulty and repeated absorptions. The increasing slowness with which the last fraction of nitrogen is removed seems greater than can be accounted for by the diminishing pressure of the diluted gas, and craves an explanation. Parallel work with some gas other than argon as a diluent of the nitrogen is scarcely practicable, for red-hot magnesium is catholic in its affinities, but experiment with nitrogen alone at known low pressures is feasible enough. We commend the problem to the curious. In quite another field an attractive hypothesis has experienced a shock; the adornment of iron with sundry Greek characters is not to be received without question, and we are threatened in its place with carbides curious, complex, but mercifully unstable. The controversy here referred to is tending towards a middle path, and it may well be that from the store of facts accumulated by both sides a sound tenable theory of the constitution of steel may be worked out. The comparative quiescence of the conventional organic chemist, with his wearisome syntheses of insignificant substances, is matter for much thankfulness; in place of such futilities there has been useful work done in collating and systematising existing knowledge; and praiseworthy attempts are being made to gain an insight into the true constitution of carbon compounds as they exist in three-dimensional space and not on a blackboard more or less plane. Ringing the changes with hydroxyl groups and the like will be practised, we suppose, as long as the barbarous taste for bizarre pigments continues. Verily sexual selection has much to answer for.

The synthesis of useful organic products stands on a different footing. New drugs, special foods and stimulants may be produced and taken into use after proper observation of their physiological effect; but in this field no great addition to our knowledge has lately occurred. The chemical production of food stuffs is not yet, nor is it especially to be desired as long as plants continue to store diffused solar energy with an economy that cannot be approached by any other means. An illustration of the doubtful utility of seeking to produce a substance which is yielded by a natural organised material is afforded by the endeavour to prepare alcohol from chalk, coal, and water. Calcium carbide, itself a new commodity, is formed by the interaction of lime and carbon at an extremely high temperature, and evolves acetelyne on the addition of water, whence the building up of the alcohol molecule can proceed by well-known steps. But even with Niagara to help the synthesis, a field of barley and a few yeast cells may be safely backed to give the better output.

Although acetelyne from calcium carbide is unlikely to displace starch as a raw material for whiskey, yet it has undoubtedly a fair prospect of use as a lighting agent in special cases where compactness or easy transport is desired. In this case the electrician has materially helped a chemical industry, but an ill-return has been made by the chemist, who, by the aid of certain oxides, once stigma-

tised as "rare earths," and an atmospheric burner, is running electrical enterprise hard in the production of a light both good and cheap. Reverting for a moment to calcium carbide, it is interesting to note that the status of this substance for carriage is a matter of debate. Can it fairly be scheduled as "dangerous," or "explosive"? As far as we know, the heat of formation of calcium carbide, whether negative or positive, has not been determined; acetylene, its hydrogen derivative, is an endothermic body, and would probably be looked upon as in itself an explosive, apart from its capability of yielding an explosive mixture with air. The matter will eventually require some formal ruling.

Another chemical industry, intrinsically small, but of importance as being supposed to involve risk to life, has bulked large before the public eye during the past year. Oxygen manufacturers will be sorely hampered if a scare arise over the occasional accidents which have occurred with cylinders of the compressed gas. Within the last few days a chance dispute and trivial assault have led to the deliverance of an *obiter dictum* worthy of the J. P. of the comic papers rather than of a clear-headed stipendiary, and non-technical papers have hastened to add comments as temperate as they are intelligent. Seeing that the question is now under investigation by a competent committee of enquiry, it is to be hoped that ignorant clamour will be suppressed or left unheeded until a report has been issued.

Another matter eminently of topical interest is the attainment of very low temperatures and the liquefaction of gases usually regarded as "permanent." Here, again, it would be hard to draw a distinction between the scientific and industrial aspect of the subject. From the early days of Cailletet and Pictet, liquid oxygen has been known, and since that time several investigators, notably Wroblewski and Olszewski, have made accurate observations of its properties. In this country the public has been indebted chiefly to Professor Dewar for many popular expositions of the methods used for achieving these results, and for the interest which he has succeeded in arousing in those to whose munificence much new and costly apparatus is due, but it has been left to a German engineer to eclipse all previous attempts to translate the results of the laboratory into the language of the manufactory. The Linde process, as described by Herr M. Schröter, has been dealt with in these columns too recently to need lengthy comment in the present article, but it is worthy of more than cursory mention, inasmuch as it involves the novel application of important principles, which have been much overlooked or utilised but imperfectly by previous investigators. Its merit and interest largely consist in the fact that no subsidiary or intermediate cooling agent is necessary, Thus, at a stroke, the need for expensive and complicated apparatus designed for liquefying and evaporating various intermediary gases, *e.g.*, carbon dioxide, ethylene, and the like, is removed, and the *raison d'être* of such elaborate mechanism as that of which the Royal Institution has hitherto been justly proud, largely disappears. No doubt that enterprising corporation will wisely replace its obsolete apparatus with a modern and rational plant.

Some time after our publication of a description of the Linde process, Professor Dewar demonstrated, on a purely laboratory scale, the practicability of the method, using a pretty little apparatus consisting essentially of a reservoir of compressed air and a coiled copper tube, having a pinhole at its further end, a rough approach to cumulative cooling being obtained by allowing the air, cooled by expansion through the pinhole, to stream past the coils of the tube conveying a fresh supply of compressed air. The experiment can be projected on to a screen by the aid of a lantern for the benefit of a popular audience. The intellectual pleasure derived from the consideration of the Linde process is only momentarily dimmed by the regret that the distinction of devising it has not fallen to a fellow-countryman.

The heavier chemical manufactures have shown less progress than have those in which less capital is sunk, or which are new and more immediately dependent on recent discovery.

Such developments as have taken place in the alkali trade have been financial rather than technical. The electrolytic production of caustic soda and chlorine is in a better industrial position than in former years. The time of experiment is nearing its close and that of commercial manufacture is setting in. It is hard at present to judge which. if any, of the methods now at work is likely to prove capable of earning a dividend, and the difficulty is enhanced by the vigorous polemics of the exponents of rival processes, some of whom have not scrupled to attack their competitors on false grounds. The ridiculous and ignorant attacks on the Castner process—which is quite sufficiently handicapped by its intrinsic defects—on the score that the mercury needed in its working will permeate human organisms employed in carrying it out, furnish a case point. Of the Greenwood process, which at one time promised well, but little has been heard, and a semi-secret method, the Hargreaves-Bird, has yielded nothing more tangible than acrimonious discussion. In all cases the efficiency is still low, and the plant is cumbrous; but the former is being improved, and the latter is at least less in constant need of costly renewals than were the earlier apparatus for industrial electrolytics. With an allusion to an especially elegant application of a discovery in pure chemistry we will conclude an article already somewhat lengthy. Since the preparation of nickel carbonyl, Mr. Ludwig Mond has wrought unsparingly at the utilisation of this substance for winning nickel from its ores. He has now so far succeeded as to be able to work up 1½ tons of nickel per week from Sudbury nickel-copper matte. We offer him our congratulations on his perseverance.

DEFECTS have been developed in one of the 67-ton guns of H.M. first-class battleship Anson to such an extent that a new gun is to be supplied.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

LAST year opened with a drop in all classes of iron rolled by the "list" iron houses in this part of the kingdom of 10s. a ton, making marked bars £7, and the Earl of Dudley's quotation £7 2s. 6. Other classes of marked iron at the same time became proportionately lower. At the January quarterly meeting, the makers of unmarked iron formed an association with a view of strengthening prices. Bars at this time were £5 per ton, and quotations were raised nominally 5s. per ton. But the advance was not generally realised, and it was not until April that any appreciable improvement in trade took place. Between July and September the prices of unmarked bars were advanced three times by the Association, and the price went up to £5 15s., and even in a few cases £6. The full advance was not, however, maintained the last two months of the year, and in the closing month prices fell back to £5 10s. per ton. Both black and galvanised sheets have improved £1 per ton during the year. In April galvanised sheets advanced about 5s. per ton, the price becoming £9 10s. for 24 w.g., delivered Liverpool, and another 5s. rise was established before the end of that quarter's meeting, the quotation being £9 15s. to £10 per ton, f.o.b. Black sheets last January were selling at £6 5s. to £6 10s. per ton for doubles, and lattens £7 to £7 5s. During the first six months of the year they advanced proportionately to galvanised sheets, and in the second half of the year the improvement was a good deal more marked, owing largely to increased demand for galvanised sheets from India, South Africa, and Australia, and some of the States of South America. With the exception of common bars and sheets there were no marked advances during the year in finished iron, but hoops and thin strips have improved from £6 5s., which was the quotation at the opening of January, 1895, to £6 10s. at the present time, and tube strip from £5 5s. last January to £5 12s. 6d. at date.

The local pig iron trade has not seen much change in 1895, the greatest attraction having been in the prices of Midland pigs imported into this district, such as Derbyshire, Northampton, Lincoln, and similar metals. The chief imports took place in the second six months of the year, when Northampton forge iron rose from 39s. to 44s. per ton; Derbyshire, 39s. to 44s., and 45s. per ton now; and Lincoln iron to 44s. 6d. and 45s. net. Staffordshire cold blast all mine iron advanced about 7s. 6d. per ton, to 97s. 6d.; part mine pigs, from 40s. to 45s.; and cinder pigs 2s., bringing the price up to 37s. per ton.

That trade is on the up grade at date is shown by the character of the last returns for 1895 made to the Iron Trade Wages Board. This return was for the months of September and October, and declared the average selling price obtained for all classes of manufactured iron in that period to have been £5 12s. 7d. per ton, or an increase on two months previously of 2s. 4d. per ton; and it is believed that the average selling price for November and December when it comes to be declared by the accountants will show further improvement. The other four Wages Board returns for the year were as follows:—January and February, 1895, £5 13s. 5d.; March and April, £5 13s.; May and June, not declared; and July and August, £5 10s. 3d. The small advance of 2s. 4d. per ton in September and October average over the two preceding months, whilst the market reports of the same date stated that ironmasters were obtaining at least 10s. per ton advance on marked bars, and 15s. to £1 advance on sheets, is largely explained by the fact that marked bars and other classes of best iron were not advanced at all. Ironworkers' wages have remained at 7s. 3d. per ton for puddlers throughout the year, and millmen's wages in proportion.

The market is at present without any intimation from the marked bar makers of their intention to declare any advance in prices this month, and, the 1st of January being passed, it is believed that there is to be no change either before or at the quarterly meetings. The new year prices of the list iron houses may, therefore, be safely quoted at £7 for bars; hoops, £7 10s.; sheets to 20 w.g., £8 to £8 10s., 24 w.g. £9 10s. to £10, and 27 w.g. £11 to £11 10s. Best sheets are £1 10s. per ton above these rates, and double best £2 10s. Boiler plates are quoted £8 to £8 10s.; best ditto, £9 to £9 10s.; best best, £10 to £10 10s.: treble best, £11 to £11 10s.; and extra treble best, £14 per ton.

Satisfaction is generally occasioned by what is now understood to be the intention of the marked bar firms to make no change, and it is pointed out that if any advance had been declared the only result would have been to drive orders still more into the hands of the unmarked bar makers, a state of things the best houses are indeed particularly wishful to avoid. With trade in its present state, £1 10s. per ton is quite sufficient difference to exist between common and best bars, if makers of the latter are to secure orders, since the quality of what are termed "common bars" is much superior to what it used to be, and consumers will not now pay such great deal higher prices for best over common bars, as was once the case.

The marked bar makers have recently been experiencing a decidedly better demand than in the early part of 1895, and they will be wise if they continue to encourage orders by every means in their power.

Sheet iron prices open 1896 at £7 2s. 6d. to £7 5s. as the market price for doubles in the black state, the bulk of producers demanding the larger figure—lattens, £7 17s. 6d. to £8; and singles, £7 per ton. Galvanised corrugated sheets are £10 7s. 6d. to £10 10s.; and £10 12s. 6d. for 24 w. g., f.o.b. Liverpool, ordinary brands, and £11 to £11 10s. for best brands. Merchants profess to require 10s. per ton for black steel sheets over iron, which, upon the present basis, would make black steel doubles £7 12s. 6d. to £7 15s., and lattens £8 7s. 6d. to £8 10s., nominal. But the market generally declines to concede anything like so large a difference, declaring that the makers of the article only quote a difference of 5s., and in some cases only 2s. 6d. per ton, between iron and steel. Sheets for tray making by the Japanese are quoted £9 5s for material of Staffordshire make, and £8 10s. for South Wales sheets, delivered up here. Trunk making sheets, also for Japanese use, are quoted by merchants £8 7s. 6d. doubles, and £9 to £9 2s. 6d. lattens; while deep stamping sheets, such as are employed by the enamellers, and similar hardware manufacturers, are priced by middlemen at £8 10s., singles; £9 10s., doubles; and £11, lattens.

Structural engineers during 1895 have experienced a sensible improvement in demand, and at date structural iron work is in brisk request from India and South Africa, Japan, and some parts of South America. Most of the bridge builders in this district can now see their way to full employment over the first three or six months of 1896. There is one drawback to this otherwise bright picture, and that is, that unfortunately the contracts in many cases have had to be taken at prices that have only the smallest margin of profit, so keen is competition from the other parts of the kingdom. But this is a matter which will right itself as the trade revival continues and developes. In the railway rolling stock branch, and in wheels and axles, and general railway material, business was very quiet in the early part of the year, but since then good orders have come to hand, largely on export account, and the makers are now nearly all busy, and have excellent prospects. Machinists and engineers in and around Birmingham have been busy chiefly on mining machinery for South Africa and Western Australia, rolling mills for sheet and tube work, pumping and gas engines, lathes and arsenal tools, and shop tools of various kinds adapted to local requirements. The demand for steam engines and motors is still adversely affected by the improvements and increasing powers and adaptability of gas engines, and boilers are sharing this experience; but what the steam engine makers lose the gas engine firms and the electrical machinery firms get. These last are as full of work as they can well be, and the indications are all in the direction of a memorable year ahead for them. A current feature in the Birmingham machinery outlook that should not be passed over without satisfactory note is the great field—never before so large or so promising—for its employment which is assured for 1896, in connection with the cycle and seamless tube trades, and the increasing extent to which machinery is being used in the manufacture of every description of brass and copper goods.

I regret to have to record the death, at the age of 66, of Mr. James Caffer, of Walsall, for many years the secretary of the operative section of the Staffordshire and Midland Iron Trade Wages Board. Mr. Caffer was one of the most widely known ironworkers' agents throughout the kingdom, and his influence in iron trade labour struggles throughout Lancashire, South Yorkshire, Derbyshire, Staffordshire, and the Midlands generally, was once very great. He resigned his official connection with the Midland Board seven years ago, owing to paralysis, and was succeeded by Mr. Ancott.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—Apprehensions of possible foreign complications, and continued labour disputes at home, have had a somewhat depressing effect upon the opening of the year. The customary holiday interference with ordinary business and industrial operations—engineering and iron works and collieries being mostly closed over the greater part of the week, and the usual 'Change meetings little more than nominal—render it of course impossible to form any very sound estimate for the moment of the real condition of trade. So far as there is anything to judge by, the actual position is unchanged, both makers and manufacturers starting the year with plenty of orders on their books, and engineering shops for the most part similarly situated as regards work in hand; but the general tone is not so buoyant, and the immediate outlook for the future is not so satisfactory as it was a short time back.

Neither the iron nor the coal Exchange meetings at Manchester on Tuesday brought together an average attendance for the closing market of the year, and on both Exchanges business was extremely slow. In the iron market the business coming forward scarcely afforded any real test of prices, but for local and district brands of pig iron makers, who are mostly well booked for the next month or two, quote nominally late rates, and are for the present indifferent about new orders. Outside brands offering here are, however, decidedly easier, owing to the continued downward movement in warrants, and iron held in second hands especially is very irregular in price. So few transactions have been put through that it is difficult to give anything like reliable quotations, except that 45s. 6d. to 46s. net cash may be said to represent about the average for foundry Middlesbrough, delivered Manchester, with Eglinton about 47s. net prompt cash, delivered Lancashire ports.

For finished iron, makers, whose books are mostly well filled over pretty nearly the first quarter of the year, remain very firm at their full list rates, not quoting under £5 10s. for Lancashire, £5 15s. for North Staffordshire bars, £7 10s. to £7 12s. 6d. for sheets, and £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths of hoops, delivered Manchester district, and 2s. 6d. less for shipment.

In the steel trade, the position continues weak, ordinary foundry hematites being obtainable at 55s. 6d. to 56s., less 2½d., with Scotch steel boiler plates to be bought at £6 to £6 2s. 6d., and local makers quoting £6 5s. delivered Manchester district.

Only a hand-to-mouth sort of business is being done in the metal market, buyers holding back in the expectation of some reduction in list rates for manufactured goods, but as makers are not holding any meeting for the next week or ten days, prices, for the present at least, will remain unchanged.

For a few days prior to the holiday stoppages of the pits there has been a little extra push of orders in the coal market, chiefly, however, for house fire qualities; but the generally unsatisfactory condition of this branch of industry remains practically unchanged, with prices not more than maintained at late rates, and no indication of any possible upward move, except perhaps some stiffening upon the low figures recently taken for engine fuel, which is not quite so plentiful in the market as it has been. At the pit mouth average prices remain at about 10s. to 10s. 6d. for best Wigan Arley; 9s. to 9s. 6d. for Pemberton 4ft. and seconds Arley; 7s. to 7s. 6d. for common house coal; 6s. to 6s. 6d. for steam and forge coal; 4s. 6d. to 5s. for best slack; and 3s. to 3s. 6d. for common sorts.

Here and there rather more business is reported to be stirring in the shipping trade, but generally there is no real improvement, and prices continue quite as low as ever, ordinary steam not fetching above 7s. to 7s. 6d., delivered ports on the Mersey.

Barrow.—There is a steady tone at the close of the year in hematite pig iron, and although comparatively little business has been done in hematites during the holidays, there is a very good and strong feeling in the market, and there are indications that a much fuller and a more pressing demand for prompt deliveries of metal will be experienced with the New Year. Prices are slightly lower at 46s. 4½d. net cash sellers, buyers being at 46s. 4d. Makers' iron is nominally quoted at 48s. There are 36 furnaces in blast, compared with 31 in the corresponding week of last year. Stocks have increased during the week 4316 tons, and close at the end of the year at 274,700 tons, compared with 115,525 tons at the beginning of the year.

Iron ore is in steady demand at old rates, average qualities being quoted at 10s. per ton net at mines, with best descriptions at 12s. 6d. per ton.

Steel makers have been on holidays all the week, but all the mills at the Barrow works will be started on full time on Monday, with prospects of plenty of work for the year. Rails are especially brisk, and shipbuilders are beginning to ask for deliveries of plates.

Shipbuilders and engineers are very busy, and arrangements are in progress for a very busy year's trade. This is likely to be equally the case with important commercial work as it is at present on Admiralty work. H.M.S. Dons will be launched at Barrow on the 29th February, and a Clan liner is to be launched on February 1st.

The coal and coke trades are steady, and prices are firm. A fuller demand is anticipated.

The shipping trade is depressed. Exports from West Coast ports during the week represented 2405 tons of pig iron and 8307 tons of steel, compared with 780 tons of pig iron and 6006 tons of steel in the corresponding week of last year. The total shipments of pig iron during 1895 amounted to 272,615 tons, and of steel to 369,321 tons, comparing with 351,630 tons of pig iron, 379,273 tons of steel in the previous year.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

CHRISTMAS of 1894 was like a leaf out of the book of summer. Christmas of 1895 promised to be what is known as thoroughly seasonable. Snow began to fall on Christmas Eve, and next day the neighbourhood was white with a keen frost; but it did not last long, and now the weather is excessively mild, although there have been one or two very cold "snaps" in the interval.

Mr. Benjamin Pickard, M.P., and several other officials of the Yorkshire Miners' Association, were in conference on Christmas Eve with the management of the Hickleton Main Colliery Company, Bolton-on-Dearne, with a view to the settlement of a dispute which has existed since August 20th last. The conference took place at the Royal Victoria Hotel, Sheffield, and, after a prolonged consideration of the whole question, an agreement happily was arrived at. The question in dispute was the difference between the Cadeby Main price list and the Houghton Main price list. The colliery owners wished to adopt the former as the basis of wages, while the miners stood out for the adoption of the Houghton Main list pure and simple. The terms arranged are practically a compromise between the two lists, and the agreement is regarded as equitable by both sides. It is expected that work will be resumed early in the New Year.

In the coal trade generally not much disquietude is expressed with regard to the Rosebery arrangement expiring by effluxion of time in June next. With reviving commerce, both sides will be slow to encourage any tendency towards strife. The employers require peace to consolidate the fruits of waiting for the better times now believed to be at hand. The workmen are anxious to begin adding to their nest eggs in the savings banks, which were largely drawn upon, and in many instances completely exhausted, during the dispute, while the inadequate employment which has been given since prevented anything being done in the way of thrift during the last year. The miners' leaders, too, can do with a period of rest to get their unions into more effective condition. All round the indications are for a season in the Midlands devoid of grave industrial difficulty.

The death at Heysham, Morecamoe, of Mr. Samuel Marshall, formerly a Sheffield manufacturer, recalls some of the stirring incidents of the Trade Union outrages. Mr. Marshall was the inventor of the double-spring sheep shears, and in the development of machinery and other ways of facilitating the manufacture, incurred the displeasure of Broadhead, who was the Robespierre of the Sheffield Industrial Reign of Terror, which was crushed by Royal Commission. Mr. Marshall left Sheffield some seven years ago, and has since resided in the pleasant village close to the favourite Bradford health resort, in the sea inlet known as Morecambe Bay.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

APART from its being a holiday time, there is very little disposition manifested to do business, and the tone is less sanguine than it was a month ago, commercial men being less ready to speak good of the prospects of the early future, which they now consider to be uncertain. Almost every indication during the first half of last month was favourable to a continuation of the improvement, and to its being more pronounced than it was in 1895, but President Cleveland's manifesto appears to have altered all that, and though the disquiet created has somewhat subsided, the iron market does not show any recovery, and there is no doubt that a considerable time must elapse before confidence can be restored. It is unfortunate for manufacturers that this check should come just when they appeared to be "out of the wood," and when consumers were beginning in almost all branches to buy with some approach to freedom. But as it is, the year closed with rather a downward tendency in prices, the only department where they were maintained being the rail trade.

The large increase in stocks of Cleveland pig iron in December would itself not have tended to weaken the market, for that is always expected in the winter, and the excess of production is usually cleared off in the spring, when the export trade becomes brisk. Last winter the output exceeded the consumption by about 100,000 tons, so that the increase in December was not likely to have much detrimental influence on the market. Still, if we sum up the trade of the year 1895, there is not as much reason to be satisfied with it as might be expected, for make and deliveries of pig and finished iron were smaller than in the previous year, while stocks have increased to a greater extent. The average prices, too, except for rails, were below those of 1894, but the best feature of the year was that while in 1894 trade was on the downgrade, in the past year it was moving upwards, and the best prices were in the latter part of the year instead of the first quarter, as in 1894. The average number of furnaces in blast in the North of England in 1895 was 89, against 93 in the previous year, and the output was 63,000 tons less, but nevertheless the increase in stocks was larger, which would indicate a smaller consumption. The stock of Cleveland pig iron had gone up at a rapid rate in Connal's public warrant stores, for at December 31st the quantity held was 171,700 tons, the increase being 15,352 tons, and for the year 77,962 tons. Of hematite pig, 138,944 tons were held at December 31st, this being an increase for the month of 8157 tons, and for the year of 58,358 tons. Thus the aggregate increase in Connal's stock last year was 136,320 tons. Of Cleveland iron the largest stock ever held was 350,000 tons in September, 1888, and the smallest, 10,000 tons in September, 1892, just after the Durham strike. The average prices for the year have been for No. 3 Cleveland pig, 35s. 9d., which was the same as in 1894; for mixed numbers of hematite pig iron, 43s. 8d., against 44s.; and of manufactured iron, £4 15s. 2d., against £4 17s. 8d.

The price of No. 3 Cleveland pig iron was brought down this week to 36s. 6d. for prompt delivery, though most sellers asked 36s. 9d.; but there was no desire shown to either sell or buy iron for forward delivery in the present uncertain state of the market. Cleveland warrants have dropped to 36s. 5½d. cash, having fallen 4d. during the last day of the year. The commoner qualities of Cleveland iron have not shown so much weakness as No. 3, as they are scarce, and they are now relatively dearer than No. 3, circumstance which has not been observed for several years. Some people think that before the winter is over grey forge may be at a higher price than No. 3, as it has been more than once during the last dozen years. Mixed numbers of East Coast hematite pig iron are firm at 46s. per ton, that being only 1s. below the best price of 1895, but 4s. 6d. above the worst. Cleveland No. 3 iron has fallen more than that—3s.—and it is only 2s. 2½d. above the worst. Rubio ore is 12s. 6d. per ton, delivered at wharves on Tees, and the freights are easier. Blast furnace coke is steady at 13s. per ton, delivered Middlesbrough furnaces, or 14s. 6d. f.o.b.

The finished iron and steel trades are quiet, but steel manufacturers are by no means badly off for work, and it is only the holidays and stocktaking that limit operations this week. Especially is this the case with the rail manufacturers. The North-Eastern Steel Company are wells upplied with orders. The demand for steel girders is increasing, but low prices have to be taken to compete with the Belgian manufacturers, who can deliver as cheaply in London as any of the British manufacturers. Producers of steel plates and angles are well off for contracts, but generally the demand for iron plates and angles does not admit of full work at the mills, the revival having extended to these departments but to a small extent. Steel rails—heavy—are at £4 15s. net. Steel ship-plates are £5; steel boiler-plates, £6; steel ship angles, £4 15s.; iron ship-plates, £4 17s. 6d.; iron boiler-plates, £5 17s. 6d.; and common iron bars, £4 17s. 6d., all less 2½ and f.o.t.

The engineering industries show improvement in that the works are more fully employed, but in the matter of prices there is not much alteration. This year will probably see considerable developments in the engineering and shipbuilding industries of Tees-side, as Sir Raylton D xon and Co. have acquired the necessary land, and propose to lay down a graving dock. Sir Christopher Furness has become connected with the firm of Messrs. Westgarth, English and Co., marine, &c., engineers, North Ormesby, and the works are to be enlarged; indeed, it is reported that £50,000 worth of new machinery is to be added. Sir C. Furness is still negotiating for the purchase of another engineering establishment and a shipbuilding yard on Tees-side, and it is expected that the matter will be ripe for submission to the shareholders within the next two or three weeks. Messrs. Palmer's Shipbuilding and Iron Co., Jarrow-on-Tyne, has received an order from the British Admiralty for two 30-knot torpedo boat destroyers. Mr. John Blumer has this week retired from the firm of John Blumer and Co., shipbuilders, North Dock, Sunderland, and the business will in future be carried on by Col. Robson, and Messrs. Thos. R. and Wm. Blumer, sons of the retiring partner, under the old style. Messrs. Ashmore, Benson, Pease, and Co., Stockton, have secured an order for a large gasholder for Derby on their patent plan, and also one for Manchester. The Whessoe Foundry Company is supplying a large steel tank and telescopic gasholder to the Danish Gas Company at Aalborg, and also a variety of gas-making plant to the same company's Copenhagen works. The negotiations which have been for a considerable time in progress between Messrs. Bell Brothers and Messrs. Brunner, Mond, and Co., for the purchase of the soda works of the former, have been completed, and the property passed over to purchasers on Wednesday, together with a large tract of land, on which Messrs. Brunner will lay down an extensive plant, the new works to be completed by the end of this year, or early in 1897. Mr. Hugh Bell joins the directorate of Messrs. Brunner, Mond, and Co.

The holidays are limiting the production of coal, as the majority of the collieries in Durham and Northumberland are stopped this week, but last week was a fairly brisk period, and exports were good in spite of the stormy weather. Some of the Durham colliers having expressed dissatisfaction with the working of the Conciliation Board, and going so far as to propose its abolition at one of the general meetings of their association, the miners throughout the county have been asked to vote by ballot as to whether the Board shall be terminated. The returns of the lodges in some cases have been made known, and certainly are not in favour of a continuance, which is to be regretted.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

BUSINESS has been confined to narrow limits this week in consequence of the New Year holidays, which still continue to be everywhere observed in Scotland. In the case of works of any size and importance operations have been suspended during the greater part of the week. The pig iron market was held on Monday and Tuesday, and then closed till Friday afternoon, when it met for a couple of hours. Prices of pig iron warrants were depressed early in the week, a very considerable quantity of iron changing hands at declining rates. The market suffered in sympathy with adverse movements in stocks and copper. Scotch warrants sold from 45s. 8½d. to 45s. 3½d. cash, and 46s. to 45s. 5½d. one month. There was only a small business in Cleveland warrants at 36s. 9d. to 36s. 5½d. cash. Hematite was also quiet, Cumberland warrants being done at 46s. 3d. cash, and 46s. 6d. one month.

The prices of makers' pig iron are as follows:—Govan and Monkland, f.o.b., at Glasgow, Nos. 1, 47s.; Nos. 3, 45s.; Carnbroe, No. 1, 47s. 6d.; No. 3. 45s. 6d.; Clyde, No. 1, 50s.; No. 3. 47s.; Calder, Gartsherrie, and Summerlee, Nos. 1, 50s. 6d.; Nos. 3, 47s. 6d.; Coltness, No. 1., 53s.; No. 3, 48s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 48s. 6d.; Carron, at Grangemouth, No. 1, 53s.; No. 3, 49s.

The shipments of pig iron from Scottish ports in the past week were 6013 tons, against 6194 in the same week of 1894, and of the total there was sent to Italy 460, Australia 335, Canada 25, South America 50, India 154, France 80, Germany 175, Spain and Portugal 55, other countries 25, the coastwise shipments being 4654 compared with 6194 in the corresponding week. At the time of writing the official returns are not available, but the pig iron shipments for the year have amounted in round numbers to 300,000 tons, compared with 248,000 in 1894. The coastwise shipments were 186,000, against 126,000 in 1894, and the foreign shipments 114,000 compared with 122,000 in the preceding year. From the figures it appears that our exports in pig iron are unsatisfactory; indeed, they are gradually declining year by year, and the West of Scotland is becoming much more of a consuming than an exporting district.

The finished iron and steel departments are necessarily quiet, merchant's offices having been closed, and works shut down a great part of the week.

Prices of coals have been low during the whole of 1895, and they are at present about the poorest level, main coal being quoted, f.o.b. at Glasgow, 5s. 9d. to 6s.; splint, 6s. 9d.; ell, 6s. 9d. to 7s.; steam, 7s. 6d. perton.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE Merthyr district was startled on New Year's Eve by the announcement that notices had been issued to the Plymouth colliers, about 3000 in number, to the effect that on and from January 31st all contracts would cease and determine. What the manager requires is the acceptance of a reduction of wages, which would about equalise the rate paid at adjacent collieries. This properly falls into adjustment by arbitration.

It has for some time been a subject of comment in the district that the ruling prices in the iron and steel trade are too low, and this has been forcibly shown during the last week by the auditor's report of the investigation of the iron masters' books. This report determines the continuation of present wages to the end of next quarter. Operatives express their dissatisfaction somewhat forcibly on the working of the scale, though the more reasonable hope that spring business will bring a change. Fairly large rail orders are in band, and there is a steady continuance of bar make in the principal works. Large cargoes of bar are coming in also from the North.

Taking the week, it must be regarded as a broken one in all industries, and in iron and steel particularly. At Swansea it was reported this week on 'Change that since the last meeting Scotch, Middlesbrough, and hematite pig were lower by 1s. per ton. Last quotations are: Glasgow, 45s. 4d.; Middlesbrough No. 3, 36s. 5d.; hematite, 44s. 4d. Other prices were as follows:—Welsh bars, £5 5s. to £5 7s. 6d.; sheet iron and steel, £6 5s. to £6 10s.; steel rails, heavy sections, £4 10s. to £4 15s.; light, £4 15s. to £5 10s.; Bessemer steel, tin-plate bars, £3 17s. 6d. to £4.

On 'Change, Cardiff, a different quotation ruled for bars, Bessemers being quoted at £4 2s. 6d. to £4 5s., and Siemens best from £4 5s. to £4 7s. 6d. There was no change in tin-plate prices, but I shall not be surprised at different rates prevailing in next week, as exports last week have been large, 82,078 boxes, while 71,925 boxes came in from works. Stocks are now down to 135,517 boxes. At Briton Ferry a good deal of work was stopped Christmas Eve, and was not resumed until Friday.

There was a good deal of animation at the Cardiff Exchange, and it was pleasant to note that a degree of hopefulness prevailed in the coal trade, and that prices were firmly maintained. Midweek this was very noticeable, and prices were as follows:—Best qualities, steam, for prompt shipment, 10s. 3d. to 10s. 6d.; and best seconds, 10s.; and ordinary seconds, 9s. 6d. to 9s. 9d.; dry coal, 9s. to 9s. 3d. Small steam continues a drug, and prices vary from 3s. 6d. to 5s., according to quality. The very best for bunkering purposes sells at 5s. to 5s. 3d. House coal is now in its old form, and prices are firm in all departments. Best house is quoted at 10s. 9d. to 10s. 11d.; No. 3 Rhondda, 9s. 9d. to 10s.; brush, 8s.; small, 6s. 3d. to 6s. 6d. No. 2 Rhondda is in great demand, as a useful coal, from 7s. 9d. to 8s.; through, 6s. 3d. to 6s. 6d.; small, 4s. 3d. to 4s. 6d. Swansea prices are:—Steam, best, 9s. to 9s. 6d.; seconds, 8s. to 9s.; No. 3 Rhondda, 10s. to 10s. 9d.; No. 2, 8s. 9d. to 9s. 6d. Monmouthshire best, 8s. 6d. to 8s. 9d.; seconds, 8s. to 8s. 3d.; best small, 4s. 6d. to 5s. 3d.; other qualities, 4s. to 4s. 3d. Patent fuel moderately good at Cardiff, Swansea, and Newport. One good cargo, of 2000 tons, left the last-named port this week for France. Prices unchanged. Coke at Cardiff is in a firm, healthy condition, prices 12s. to 14s. for furnace; foundry, 15s. to 15s. 6d.; special, 19s. 6d. Iron ore prices stationary. Cardiff prices: Best Rubio, 11s. 9d.; Tafna, 11s. to 11s. 3d.; Garucha, 10s. 9d. to 11s. It is not expected that any marked change will take place in this branch for a time, until the weather improves, though during the present week some good cargoes have come in.

Welsh industries have been honoured by the Queen this week in the person of their chief representative, Sir William Thomas Lewis, who has been created a baronet, in recognition of his great services in the coal and iron and steel trade.

It is too early for full statistics of the coal trade of 1895. This, however, may be stated, that for the eleven months ending November the exports amounted to 12,157,000 tons; and December, 1894, 999,000 tons, and we have for the twelve months ending November, 1895, 13,156,000 tons. The quantity for the same period of 1894 was 13,348,000 tons.

Pitwood continues inactive. Large cargoes are coming in, and it is expected that present prices—16s.—will be altered to 15s. 6d. or 15s. 9d. in a day or two, Cardiff.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THERE is actually nothing of interest or importance to be told with regard to the iron and allied trades this week, business transactions in the different departments having been very limited on account of the holidays.

The Silesian iron market has been comparatively dull, although prices maintain a firm tendency. But there have been less orders given out lately, and stocktaking and repairing at the works tends to increase the quiet tone which has recently been noticeable. However, the contracts booked during the preceding months will keep up a regular activity at the mills and foundries for some time to come. The prices realised for common forge pig were M. 50 to 51 p.t.; foundry pig, M. 50 p.t.; basic, M. 52 to 53 p.t. at works. The demand for finished articles of iron and steel likewise shows a slight decrease, but, on the whole, manufacturers report themselves pretty well supplied with orders of previous date. At the steel works a fair activity is going on, the requirements for railway and engineering purposes being rather large. For export there is not much doing, especially the business to Russia showing a falling off.

No appreciable improvement can be reported as regards the position of the Austro-Hungarian iron trade, the weight of business put through being extremely limited. There is never much doing at this period of the year, but the demand for iron and steel has been very small for some time past, and there is now a decided depression and dulness noticeable in iron circles, the more so because foreign competition is exceedingly keen. Quotations are, on the whole, unaltered, being for common forge pig, 46fl. to 47fl.; grey pig, 48fl. to 51fl.; Bessemer, 49fl. to 51fl.; ingots, 78fl. to 85fl.; Styrian bars, 105fl. to 112·50fl.; girders, 106fl. to 110fl.; heavy plates, for boiler-making purposes, 165fl. to 180fl.; tank plates, 135fl.; steel plates, 142·50fl.; galvanised sheets, 205fl. to 260fl.; all per ton. Tin sheets are quoted 28fl. per box.

Though there is a decided lull in the Belgian iron business, prices are not weaker, because manufacturers are, as a rule, so well supplied with contracts that they can afford to hold off from selling at the present. The plate makers have resolved at a recent meeting to firmly maintain their former quotations, only steel plates for export were reduced to 135f. p.t. Steel rails are very firm at 110f. p.t., f.o.b. Antwerp. Comparing prices of 1st November and 1st of December, no alteration whatever can be perceived. On the 1st of December there were twenty-seven blast furnaces in blow out of forty-three existing, ten producing ordinary pig, three foundry pig, and fourteen basic. Output of pig iron in Belgium was:—

	November.		January 1st to December 1st.	
	1895. Tons.	1894. Tons.	1895. Tons.	1894. Tons.
Forge pig	26,250	36,600	323,515	374,660
Foundry pig	6,600	8,700	77,620	74,920
Basic	34,500	31,800	357,780	375,460
Totals	67,350	77,100	758,915	825,040

There has been very little business doing on the Belgian coal market for some time past, but the cold weather which has now set in cannot fail to have a favourable influence, at least on house coal. For engine classes of fuel some pretty heavy contracts are expected to be given out after the 1st of January. Prices are firm all round. Regarding the Belgian business in coal and coke during the first ten months of 1895, there were imported in coal 1,238,340 t., against 1,133,765 t. for the corresponding period the year before; of these 621,793 t. came from Germany, against 585,019 t. for the previous year, while import from France was 349,854 t., against 295,282 t. In coke, import amounted to 329,943 t., against 269,362 t., 317,312 t. coming from Germany, against 260,490 t. for the same period in 1894. Export in coal was 3,854,767 t., against 3,686,129 t.; 3,020,589 t. were sent to France, against 2,905,002 t.; while 228,165 t., went to Germany, against 187,550 t. Export in coke was 710,133 t., against 724,593 t. last year, of which 123,394 t. were exported to Germany, against 128,895 t. for the corresponding period last year.

The tone of the Rhenish-Westphalian iron market is very confident. The activity in the raw and finished iron industry has naturally been decreasing before and after the holidays, and stocktaking will in many instances prevent a vigorous employment for the next fortnight, but a healthy business is expected to be done afterwards, and producers as well as dealers are entering the new year with much confidence. Pig iron, which has been in pretty regular request, shows much firmness in quotations. Forge pig, No. 1, is quoted, M. 48 to 52 p.t.; No. 3, M. 42 p.t.; hematite, M. 63 p.t.; foundry pig, No. 1, M. 65 p.t.; No. 3, M. 56 p.t.; basic, M. 50 p.t.; Bessemer, M. 54 to 55 p.t.; iron for steel making, M. 49 to 52 p.t., at works. For Luxemburg forge pig M. 45 p.t. is quoted. Demand in the malleable iron trade may be termed pretty lively, considering the season of the year. Prices, however, are for the present scarcely paying, and manufacturers are, therefore, anxiously waiting for the rise in quotations which the spring business is likely to bring. Bars have recently been offered at M. 103 to 111 p.t. Girders are extremely quiet just now. Plates and sheets, though less animated than before, are still in fair request. Wire and wire nails continue neglected; the same is the case with rivets. The employment of the tube foundries leaves pretty much to be desired, basis price remaining on M. 110 p.t.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THERE was a fair attendance on 'Change to-day. Steam and house coal was in good demand at last week's prices. There is no change to report in the tin-plate trade. The manufactured iron and steel trades are easier. The pitwood market, if anything, is slightly easier. Notwithstanding the dislocation of business caused by the holidays, the shipments of coal and fuel have reached nearly 70,000 tons. The ship repairing trade is quieter than it has been for a considerable time. The rapid arrival of tonnage into the port, however, will doubtless give it a fillip, and we can safely predict that in the course of a few weeks the trade will have resumed that state of great activity which was characteristic of it during the whole of last year.

Prices ruling on 'Change to-day were as follows:—Coal, best steam, 8s. 6d. to 8s. 9d.; seconds, 8s. to 8s. 3d.; best house coal, 10s. 6d.; dock screenings, 5s.; colliery, small, 4s. 6d.; smiths' coal, 6s. 6d. Patent fuel, 10s. 3d. Pig iron: Scotch warrants, 45s. 4½d.; hematite warrants, 46s. 4d., f.o.b. Cumberland; Middlesbrough, No. 3, 36s. 5d. prompt; Middlesbrough hematite, 44s. 4d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails: Heavy sections, £4 15s.; light sections, £5 5s. Tin-plate bars, £4 2s. 6d. to £4 5s. Siemens tin-plate bars, best £4 5s. to £4 7s. 6d., all delivered in the district, cash, less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 3d.; Siemens coke finish, 9s. 6d. Ternes, per double box, 28 by 20c., 21s. to 22s. Pitwood, 16s. to 16s. 3d.

AMERICAN NOTES.

(From our own Correspondent.)

NEW YORK, December 26th.

THE last half of the current year has filled mills, shops, and factories with work at high prices. The sudden expansion of demand gave an impulse to mill and factory construction. If this demand does not expand, a collapse is inevitable. The furnaces are turning out ten thousand tons of pig iron per day more than January 1st, and as long delayed requirements will soon be filled, an accumulation is inevitable. Bessemer and billets have fallen to nearly cost. Coke is to be advanced to two dollars per ton January 1st. Last winter it sold at one dollar. Lake ore companies are all preparing to rush out ore at the rate of a million and a-half tons per month during the shipping season. Never was our steel and iron-producing facilities so perfect. Furnace production is close on to 220,000 tons. Rolling mill capacity is not as crowded as a month ago. Plate and structural mills are still running full time. Bar mills in some cases have returned to single turn. The banks are well supplied with money, but commercial demands are restricted. Copper is weak and declining. Stocks of tin are very large, and prices are weaker. Lead is declining, and heavy holders in the West are trying to unload. Anthracite coal mines will run half time. The soft coal mines are producing their maximum output. Lake navigation has ceased for the winter. All the lake shipbuilding yards will be crowded with work to meet next year's tonnage requirements. A general improvement in the industries is a reasonable expectation. The present dulness is the natural result of advancing prices and undue activity during the autumn months. Prices are everywhere weakening, but the room for a drop is contracted. After the opening of the year buyers will probably renew their engagements at the current quotations.

The panic in stock has had no effect on the industrial situation. A 3 per cent. bond Bill will perhaps be passed at Washington to fill up our purse. Large gold exports have decreased the stock to 68,000,000 dols. This has resulted in the bringing forward of a measure to increase tariff duties 25 per cent. on certain articles, and which will provide an additional annual revenue of 45,000,000 dols. Our high-class securities are now in better demand abroad, according to orders received by local brokers. Railroad earnings for ten months on 132 roads show an increase of seventeen million dollars in net earnings over 1894, same time. The demand for iron and steel is moderate, owing to declining prices. The enormous production has been promptly absorbed up to this time, but as to pig iron, there is now a surplus which must rapidly grow until the weaker furnaces will be forced out of production. There is nothing to discourage steel makers beyond weak prices in 1896. A conservative course will be pursued with regard to railroad construction. The latest authoritative statements on this subject are that minimum construction requirements will be attended to. This is the present conclusion, but it is liable to be most suddenly set aside for a very different one. The iron and steel makers hold to the belief that circumstances will yet arise that will make 1896 a phenomenal year. Prices have now receded to a very low point. Crude iron production has about reached high-water mark, but makers feel it hazardous to permit a large accumulation except those few whose cost of production is the lowest. Coke price for 1896 will be fixed this week, probably at 2 dols. Companies have been recently organised to construct over 2000 additional ovens as soon as the work can be done. Steel making capacity is also being enlarged, and by the close of 1896, the United States will have a steel production capacity that will cover probable require ments to the close of the century.

LAUNCHES AND TRIAL TRIPS.

On Monday, December 30th, 1895, Sir Raylton Dixon and Co. launched from Cleveland Dockyard, Middlesbrough, the fine steel screw steamer Wolfsburg, built to the order of the Hansa Steamship Company, of Bremen, under the supervision of Mr. D. Wulff, their superintendent engineer. The principal dimensions are: Length, 323ft.; beam, extreme, 42ft. 6in.; depth moulded, 25ft. She is built to Lloyd's 100 A1 class, spar deck rule, the poop, bridge, and forecastle decks being of teak. The captain, officers, and engineers are accommodated in houses handsomely fitted up on bridge deck, and the crew and firemen are berthed in commodious quarters in topgallant forecastle. Triple-expansion engines, built to German law requirements, will be supplied by Messrs. T. Richardson and Sons, Hartlepool, having cylinders 22½in., 38in., 62in. by 42in. stroke, with two large single-ended boilers, working at 200 lb. pressure. This is the seventh steamer Sir Raylton Dixon and Company have launched for the Hansa Company within two years, another steamer being on the stocks for the same owners. On leaving the ways the vessel was named Wolfsburg by Mr. W. L. Johnson.

On December 30th, Messrs. Ropner and Son, of Stockton, launched a steel screw steamer of the following dimensions, viz.: Length between perpendiculars, 280ft.; breadth, 40ft.; moulded depth, 18ft. 6in.; which they have built for London owners, and is a sister ship to the s.s. Chiswick, launched a fortnight ago for the same owners. The steamer is built off the part awning decked rule, with poop and raised quarter deck, her deadweight carrying capacity being 3000 tons on 17½ft. The saloon and cabins for captain and officers are fitted in the poop, the engineers' accommodation being amidship. She is built on the web frame principle, leaving the holds entirely clear for cargo, and has a cellular bottom and after-peak arranged for water ballast. The engines will work up to about 750 effective horse-power, and are by Messrs. Blair and Co., having cylinders 21in., 34in., 56in. by 36in. stroke, steam being supplied by two large steel boilers working at 160 lb. pressure. On leaving the stocks Miss Nina Florence Munro, of Billingham Hall, Stockton-on-Tees, gave her the name of Richmond.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

16th December, 1895.

24,044. Cycle and Roller Skates, A. Dorst, London.
24,045. Books, F. W. J. Webb, Southampton.
24,046. Heel-protector, J. Hatschek.—(*A. Molnár, Austria.*)
24,047. Measuring Gunpowder, J. Dawber, Pemberton, near Wigan.
24,048. Power Accumulator for Cycles, J. T. Towlson, Somerset.
24,049. Electrical Contacts, A. J. Moulart and A. de Galard, Brussels.
24,050. Looms for Weaving Cloths, J. H. Cunliffe, Rochdale.
24,051. Rings for Pistons, E. W. Batt and T. Gribble, Bristol.
24,052. Microscope Eye-Rester, G. P. Richard, Southport.
24,053. Tin Opener, A. Fenton, Birmingham.
24,054. Educational Word-builder, J. H. Towers, Hants.
24,055. Electric Cable Joint Boxes, R. C. Quin, Brighton.
24,056. Pedals for Cycles, A. I., A. I. B., and A. P. Maxfield, Birmingham.
24,057. Brackets, A. I., A. I. B., and A. P. Maxfield, Birmingham.

24,289. Ozone, C. J. Yarnold, London.
24,290. Restraining Horses from Kicking, H. Cave, London.
24,291. Pneumatic Tires for Vehicles, J. H. Barry, London.
24,292. Malting Apparatus, A. Deininger, London.
24,293. Nitrogenised Water, H. J. Haddan.—(*E. Freixa, Spain.*)
24,294. Candlesticks, D. P. M. Lloyd, London.
24,295. Steam Generators, W. Eaves, London.
24,296. Electric Transformers, A. B. Blackburn and W. L. Spence, London.
24,297. Moulding Pats of Butter, W. and W. Hucks, London.
24,298. Velocipedes, A. Gravier, London.
24,299. Driving Chains for Cycles, S. H. Crocker, London.
24,300. Conduit Tramways, J. More, jun., and G. Flett, London.
24,301. Frames for Cycles and Vehicles, J. R. Trigwell, London.
24,302. Process for Deodorising, &c., A. Guillemare, London.
24,303. Rollers for Printing Fabrics, A. Haley and W. T. Wilkinson, London.
24,304. Incandescent Electric Lamps, M. Bailey and J. Warner, London.
24,305. Potato Diggers, W. Groves, London.
24,306. Sash and Axle Pulleys, F. J. J. Gibbons.—(*E. A. Maginnis, United States.*)
24,307. Stops for Window Sashes, F. J. J. Gibbons, London.

19th December, 1895.

24,308. Attaching Handles to Broom Heads, E. J. Nowell and J. T. Ayton, London.

24,309. Raising Sunken Ships, F. E. Shean, London.
24,310. Tri-reflecting Carriage Lantern, R. H. Coppin, Croydon.
24,311. Air-tight Couplings for Tubing, D. Allan, London.
24,312. Aluminium Bicycle Frames, W. Pearson, Birmingham.
24,313. Blowing Glass Bottles, &c., F. F. Warren, Dublin.
24,314. Blowing Glass Bottles, &c., F. F. Warren, Dublin.
24,315. Puzzle Game, W. Francis, D. G. Day, H. Hunter, G. C. Weston, and G. W. Hunter, London.
24,316. Hollow Column for Bedsteads, G. Rogers, Birmingham.
24,317. Textile Fabrics, G. Douglas, Bradford.
24,318. Looms, C. C. Howland, Hyde.
24,319. Cloth-covered Printing Rollers, S. Pulman, Manchester.
24,320. Pneumatic Tires, T. Lockwood and W. H. Hanson, London.
24,321. Pneumatic Tires for Cycles, G. C. Mesuard and G. G. Scurfield, Sunderland.
24,322. Heat Non-conducting Coverings, J. C. S. McLay, London.
24,323. Extracting Pickles from Bottles, G. R. Downer, Chichester.
24,324. Composition for Ships' Bottoms, T. Sheppardson, Sunderland.
24,325. Strainer for Cooking Purposes, R. W. Welbank, Banbury.
24,326. Ring for Keys and Tablets, H. G. N. Gardner, London.
24,327. Horse Collar, F. Warner, Wednesbury.
24,328. Washing Brushes, G. Holmes, sen., and G. Holmes, jun., Derby.
24,329. Tube for Pneumatic Tires, J. Moseley, Manchester.
24,330. Table Condiment Receptacles, J. Sculthorpe, Liverpool.
24,331. Night Marching Instrument, W. W. C. Verner, Birmingham.
24,332. Hydraulic Checks, R. Hodges and S. Hill, London.
24,333. Cycle Brakes, R. H. Housman and F. W. Lanchester, London.
24,334. Chains for Chain Gearing, F. J. Smedley, Nottingham.
24,335. Wheels for Chain Gearing, F. J. Smedley, Nottingham.
24,336. Cycle Saddles, W. Brown and J. Read, Leicester.
24,337. Heating Water, L. A. Chevalet and W. Boby, London.
24,338. Cycle Tubes, O. Pihlfeldt and W. G. Garnett, Birmingham.
24,339. Manufacture of Tires for Cycles, A. Kunze, Liverpool.
24,340. Venetian Blind Cord Holders, W. Hitchin, Birmingham.
24,341. Preventing Waste in Wax Candles, A. J. Pursall, Birmingham.
24,342. Spiked Plates for Boots, E. and S. Brown, Birmingham.
24,343. Cycle Wheels, J. E. Thornton and W. H. Armitage, Altrincham.
24,344. Printing Fabrics, S. Schwabe and Co. and J. Gilbertson, Manchester.
24,345. Sewing Machine, R. Haase and S. Salinger, London.
24,346. Driving Chains and Wheels, H. Renold, Manchester.
24,347. Non-automatic Syphon Cisterns, W. H. Webster, York.
24,348. Boot Protector, W. J. Fox, Manchester.
24,349. Egg Boxes, J. Laing, Glasgow.
24,350. Hay-making Machines, J. E. S. Perkins and J. Harrison, Peterborough.
24,351. A Revolving Adjustable Spanner, Colin Brothers, Southport.
24,352. Non-slip Boot Tongue, J. H. Airey, Sunderland.
24,353. Printing Rollers, T. McKillop and J. Garnett, Glasgow.
24,354. Electrical Switches, C. M. Dorman, R. A. Smith, and H. G. Baggs, Manchester.
24,355. New Reflecting Stove, T. Bergmann, Brussels.
24,356. Indicating Rotary Speed, J. Wolff, Brussels.
24,357. Drilling Wood, &c., J. E. Leeson, Manchester.
24,358. Munitions of War, &c., W. G. Rothwell, Southport.
24,359. Folding Heads of Vehicles, J. G. Harrison, Birmingham.
24,360. Lasts, A. C. York and F. S. Readhead, London.
24,361. Spring Collar Stud, R. M. Dewar, London.
24,362. Bicycle Saddles, H. A. Christy, London.
24,363. Sounding Apparatus, S. H. James, London.
24,364. Self-threading Needles, V. Milyard and S. Davis, London.
24,365. Inhaler, The Anglo-Swedish Trading Association, Ld., and G. O. Rennerfelt, London.
24,366. Resonators for Stringed Instruments, D. Mayer, London.

24,402. Sewing Machines, M. H. Pearson and Pearson and Bennion, Ld., Leicester.
24,403. Mowers, C. Hodson, Derby.
24,404. Buffing Wheels, H. A. Oldershaw, Leicester.
24,405. Elastic and Knitted Fabrics, G. Riley, Leicester.
24,406. Igniting Lamps, A. F. Richter.—(*W. Seippel, Germany.*)
24,407. Steam Rotary Motor, C. Burgess, Worcestershire.
24,408. Moulding Ceiling Cornices, &c., J. Light, Bristol.
24,409. Towels, W. H. Boyles and A. J. Curnow, London.
24,410. Manufacture of Wheel Tires, T. Sloper, Devizes.
24,411. Motors, C. T. Wordsworth, E. Wiseman, and J. Holroyd, Manchester.
24,412. Socketed Earthenware, C. J. H. Gradisky, Manchester.
24,413. Ridge Tiles for Roofing, C. J. H. Gradisky, Manchester.
24,414. Dress Suspenders, A. E. Garratt, Birmingham.
24,415. Damping Lithographic Stones, E. Tudor, jun., H. Grimshaw, and G. Daniels, Manchester.
24,416. Ball Bearing Boxes and Axles, J. Parr, Leicester.
24,417. Pneumatic Tires, S. Tweedale and J. Clegg, Manchester.
24,418. Purification of Oil, E. S. Wilson and E. Stewart, Liverpool.
24,419. Combined Cone Adjuster, W. Homer, West Bromwich.
24,420. Temperature in the Holds of Steamships, B. J. Maloney, Edinburgh.
24,421. Straining Water Pulp Apparatus, J. White, Glasgow.
24,422. Medical Spoon for Liquids, W. H. Bagley, Birmingham.
24,423. Tapestry Carpets, R. J. C. Mitchell, Manchester.
24,424. Loading Live Stock, W. J. Mead, London.
24,425. Pneumatic Tires, T. A. Hearson and W. Menzies, Surrey.
24,426. Drop-down Guns, W. Cashmore, Birmingham.
24,427. Hooks, T. R. Voce and B. Drysdale, Birmingham.
24,428. Guiding Driving Ropes, F. S. Rippingille, London.
24,429. The Over Bath Movable Washstand, A. Stunt, London.
24,430. Cornice Pole Rings, W. A. Rees, London.
24,431. Safety Pin, C. Bayer, London.
24,432. Boxes, A. M. Clark.—(*M. C. Söderlund, Russia.*)
24,433. Lifting Appliance, A. M. Clark.—(*M. C. Söderlund, Russia.*)
24,434. Vehicle Wheels, F. W. Shorland, London.
24,435. Thread Cutter for Spools, A. B. Sykes, London.
24,436. Pneumatic Tires for Cycles, S. Anyzewski, London.
24,437. Gas Lighters, The Anglo-Swedish Trading Association and O. E. Wollert, London.
24,438. Treadle Mechanism, &c., H. Gainswindt, London.
24,439. Valve Mechanism of Steam Engines, C. W. Thompson, London.
24,440. Manufacture of Sensitised Paper, W. Friese-Greene, London.
24,441. Pails, H. Goldberg and The Johannesberg Mining and General Syndicate, London.
24,442. Oil Lamps, L. E. Thornton, London.
24,443. Portable Electric Lamps, S. F. Walker, Cardiff.
24,444. Holders for Electric Glow Lamps, E. Hungerbühler and the Electrical Company, Ld., London.
24,445. Preventing Rucking in Shirt Fronts, G. A. Cartwright, London.
24,446. Brake, T. Brailsford, E. Wardle, and A. Hemsley, London.
24,447. Cyanide Solutions, C. M. Pielsticker, London.
24,448. Paper Fasteners, S. H. Crocker, London.
24,449. Lifts, C. A. Perkin and J. C. Cole, London.
24,450. India-rubber Tires, J. G. Ingram, London.
24,451. Upholstering Seats of Chairs, W. Vogler, London.
24,452. Gong Bells, N. T. Mills, London.
24,453. Hollow Projectiles, R. A. Hadfield and A. G. M. Jack, London.
24,454. Quick Folding Doors, J. C. Hudson, London.
24,455. Obtaining Pure Starch from Crude Starch, W. V. Siemens and O. N. Witt, London.
24,456. Treatment of Potato Starch, C. Hellfrisch, London.
24,457. Feed-water Filters, A. Harris, Liverpool.
24,458. Dog Muzzles, E. de Vargyas, Liverpool.
24,459. Earthenware Gully Traps, G. Brain, jun., London.
24,460. Ventilation of Drains, &c., B. S. Wagstaff, London.
24,461. Station Indicator, J. R. Hearnden, London.
24,462. Trays for Middlings Purifiers, J. Hunt, London.
24,463. Mediums for Igniting Coal Gas, T. V. Riordan, London.
24,464. Gas Lamps, F. L. Schulz, Hamburg.
24,465. Contact Button, A. C. Miles and B. F. de Morgenstern, London.
24,466. Indicators, A. C. Miles and B. F. de Morgenstern, London.
24,467. Incandescent Lamps, A. C. Miles and B. F. de Morgenstern, London.
24,468. Removable Covers on Cycle Seats, J. Maclachlan, London.
24,469. Cycles, A. Durey and L. Schreiner, London.
24,470. Valve Mechanism for Engines, C. W. Thompson, London.
24,471. Electric Circuits, V. A. Fynn and Easton, Anderson, and Goolden, London.
24,472. Electric Machines, V. A. Fynn and Easton, Anderson, and Goolden, London.
24,473. Incandescent Lamps, C. H. Stearn.—(*C. F. Topham, Switzerland.*)
24,474. Wheels for Carriages, &c., A. Reimann, London.
24,475. Polishers, R. H. Webb, London.
24,476. A New Rotary Steam Engine, F. Hamer, London.
24,477. Sewing Machines, H. H. Lake.—(*F. W. Merrick, United States.*)
24,478. Water Lifts, C. T. Burgess, London.
24,479. Compositions of Matter, R. D. Upham, London.
24,480. Brakes for Road Vehicles, F. W. Lucas, London.

21st December, 1895.

24,481. Spring Lock and Key, W. Meakin, London.
24,482. A Protector for Meat, Fish, &c., W. Poole, Somerset.
24,483. A New Weighing Machine, T. A. McKee, Dublin.
24,484. Collapsible Partition Screen, E. J. Sherman, Felixstowe.
24,485. Gas Meters, G. Haydon, F. H. Urry, and G. Sommerville, London.
24,486. Junction Marked Drain Pipes, M. Aspinall, Worthing.
24,487. Correspondence Cards, S. Learoyd, Huddersfield.
24,488. Soup Spoon, C. R. Williams, Newcastle-on-Tyne.
24,489. Making Sealing Wax, H. Bedford, Devon.

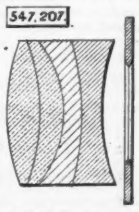
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

547,207. Lens for Optical Purposes, *C. P. Goerz, Schöneberg, and E. V. Hoegh, Wilmersdorf, Germany.—Filed July 18th*, 1895.

Claim.—A photographic objective consisting of four single lenses juxtaposited and cemented together, of which two juxtaposited lenses are positive and of different refraction, and two juxtaposited lenses are negative and of different refraction in such manner that a lens of less refraction is juxtaposited to a lens of higher refraction, for the purpose set forth.

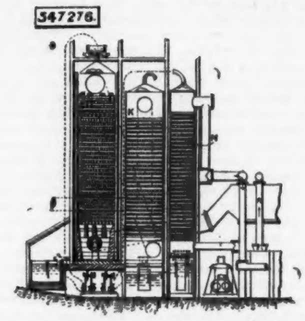
547,207.



547,276. Process of and Apparatus for Obtaining Ammoniacal Products, *L. Mond, Winnington, England.—Filed January 18th*, 1895.

Claim.—(1) The improvement in the process of extracting ammonia and tar from producer gases, and at the same time economically supplying hot air saturated with moisture at an elevated temperature to the gas producers, which consists in washing the gases with agitation in water to remove soot and dust and to condense the tar and the fixed ammonia, separating the free ammonia by means of an acid solution, passing the hot gases and water in prolonged contact with each other in reverse direction—whereby the gases are cooled methodically by the water and further ammonia and tar extracted and the water becomes heated—and passing this hot water and the air for the producer in prolonged contact with each other, in opposite directions, whereby the air is heated and saturated with moisture at an elevated temperature and the water cooled, and lastly, using the water over again to cool the hot gases. (2) In an apparatus for separating ammonia and tar from producer gases, the combination with a gas producer, scrubbers K and E for separating the ammonia, and a scrubber M for heating and saturating the air for the producer, and cooling the water for the scrubbers K and E. (3) In an apparatus for separating ammonia and tar from producer gases, the combination of producer A, scrubbers E, K, and M, and pipes and pumps connecting same, substantially as described.

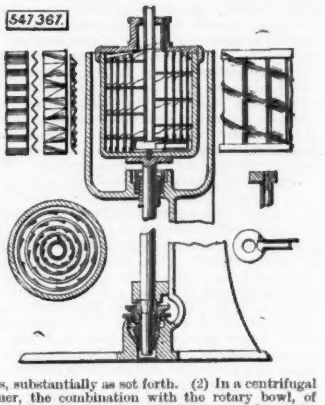
547276.



547,367. Centrifugal Creamer, *O. Anderson, Newark, N.J.—Filed June 16th*, 1894.

Claim.—(1) The combination with the rotary bowl, of plates arranged in circles concentric with the bowl and curved inward or having the concavities on the sides towards the centre of the bowl, and spirals formed at the sides of said plates to give an upward flow through the chamber between said circles of plates, substantially as set forth. (2) In a centrifugal creamer, the combination with the rotary bowl, of curved plates arranged vertically in annular series within said bowl, with openings between to allow an inflow of cream and an outflow of blue milk therethrough, and spiral partitions joining the plates of a series and giving upward movement to the separating fluids, substantially as set forth.

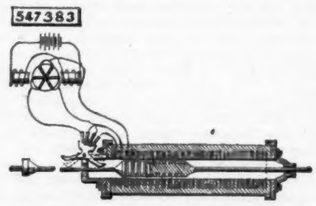
547367.



547,383. Reciprocating Electric Engine, *F. B. Rae, Detroit, Mich.—Filed May 31st*, 1892.

Claim.—(1) The combination in a multiphase reciprocating motor, of an electro-magnet having coils contained in different windings in the conductors forming the circuit of a multiphase generator, whereby a progressive field of force is produced in said magnet, a plunger for such magnet and a reversing switch, substantially as described. (2) In a multiphase reciprocating motor, the combination of an electro-magnet having a continuous iron core provided with a plurality of sets of coils contained in the different conductors of the circuit of a multiphase generator, a plunger for said electro-magnet, and a reversing switch operated by said plunger, substantially as described.

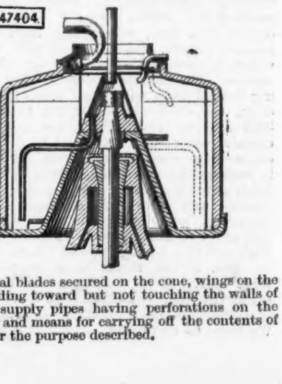
547383



547,404. Centrifugal Machine, *T. H. Springer, Philadelphia, Pa.—Filed March 16th*, 1895.

Claim.—(1) In a separator, a bowl having a conical centre, a spiral blade arranged on the cone, between the wings, feed pipes having perforations on the sides facing the centre of the bowl, and means for carrying off the contents of the bowl, as and for the purpose described. (2) In a separator, a bowl having a conical centre, spiral blades secured on the cone, wings on the cone extending toward but not touching the walls of the bowl, supply pipes having perforations on the inner side, and means for carrying off the contents of the bowl for the purpose described.

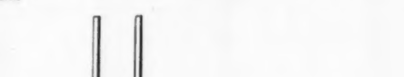
547404.



THE JENNY LIND.

WE illustrate this week an engine round which very great historical interest centres. The Jenny Lind was in a very large measure the forerunner of the standard type of English locomotive. We believe that most of our readers will admit that even in modern eyes there is much to admire in the design, and it is probable that the engine was on the whole the handsomest locomotive that had been built up to that date. The origin of the design is very instructive, and we are indebted to the private diaries of Mr. David Joy, which he has courteously placed at our disposal, for the following information.

In 1846 Mr. Joy was chief draughtsman at the Railway Foundry, Leeds, Mr. E. B. Wilson being head of the firm. Mr. John Gray was locomotive superintendent of the London and Brighton Railway. At the end of November, 1846, Mr. Joy was sent to Brighton to see him about an order for ten locomotives. Mr. Joy was employed for some time taking tracings from Mr. Gray's drawings and getting particulars. Then he travelled all over the line on various types of engines, among others, the curious locomotive with two pistons moving in opposite directions in each cylinder, designed by Bodmer. This engine some years subsequently ran off the road on the Lewes branch, killing both driver and fireman. The engine designed by Mr. Gray had six wheels, single drivers 6ft. in diameter, leading and trailing 4ft., cylinders 15in. by 24in., boiler 10ft. long by 4ft. 1in. diameter. The fire-box was square, 3ft. 4in. by 3ft. 4in., and 4ft. 9in. deep. There were 700 square feet of tube surface, and 79ft. of fire-box, and 11 square feet of grate; pressure 100 lb. There were two domes, both alike with square bases and lever safety valves. This engine was built by Hackworth, and ran very well, easily making forty miles an hour with heavy trains. There were on the line certain long boiler engines. These were much favoured, but those on the Brighton line rolled fearfully. Mr. Joy endeavoured to arrive at some conclusion as to what engine really would suit the line best out of all the types in use. He returned with the tracings of the Gray-Hackworth engine to the Railway Foundry, and began new drawings for two engines, Nos. 60 and 61. These had scarcely been begun when Mr. Gray left the Brighton line. The drawings were stopped, and orders were given that the Railway Foundry should submit designs for a new type. By Mr. Fenton's directions Mr. Joy began to scheme on the lines of the last locomotive built; one for the Leeds and Dewsbury line, with a boiler 11ft. 6in. long, outside cylinders, drivers far back, and trailing wheels behind the fire-box, and with as much heating surface as possible. About a dozen engines were sketched, and none of them appeared satisfactory. Mr. Joy went home on Saturday afternoon with his mind full of his subject, and in the evening he began scheming again, and prepared a sketch of the engine subsequently known as the Jenny Lind, so called after the famous singer whose name was just then in every one's mouth. At that time a low centre of gravity was deemed essential to steadiness. The Jenny Lind had inside cylinders 15in. by 20in., and single driving wheels 6ft. in diameter. The driving wheels had inside bearings; the leading and trailing wheels outside bearings. In order to get as wide a fire-box as possible, the inside frames stopped short at the box, as shown in the annexed sketch.



There were 800 square feet of surface, of which 80 were in the fire-box. The cylinders had the slide valves between them. The valve gear was the Stephenson link, the link being hung from the middle at one side only. Great care was taken to provide a free exhaust. The pressure was 120 lb., and the calculated weight full 21 tons.

On Monday morning Mr. Joy took his sketch to the works. It was at once approved, and he began detail drawings; various parts were strengthened, and the finished engine weighed full 24 tons. This was the origin of the Jenny Lind type, which remained for years the standard engine built by the Leeds Railway Foundry Company. It was the first high-speed really economical engine, the economy being due to excellence of workmanship and good proportion of parts; but mainly, no doubt, to the then excessive pressure carried in the boiler. To Mr. James Fenton is apparently due the credit of making the advance from 80 lb. or 90 lb., then usual, and 100 lb., then exceptional, to 120 lb. Mr. Joy says that he endeavoured to combine in the Jenny Lind all the good points of the Gray and various other engines, and we have here, no doubt, a design simple and harmonious. Our readers who are disposed to criticise it must not forget that in 1846 the design of the locomotive was in a chaotic condition; every one was feeling his way, and all manner of designs were tried, the locomotive as we have it being essentially a survival of the fittest. The Jenny Lind constituted a remarkable advance on what had gone before it, and held its own for years to come with what followed it, and this is not wonderful when we consider what the performance of the engine was in actual work.

In May, 1847, the first Jenny Lind, No. 60, on the Brighton line, was completed. The boiler was lagged with mahogany. The first run was made with it to Wakefield *viâ* Normanton, and returning, the engine was nearly run into by the Manchester mail train. The Jenny Lind was so much liked, that the Railway Foundry got numerous orders, and for some time built "Jennys" at the rate of one per week, a remarkable achievement in those days. A more powerful type of this engine was constructed with cylinders still 15in. by 20in., but with four driving-wheels instead of two, the diameter being reduced to 5ft. 6in.; the trailing driving-axle being as close to the fire-box as possible. In August, 1847, the last of the ten Jennys for the Brighton Company was finished. It had 6ft. 3in. drivers and 1000 square feet of heating surface.

Our engraving is reproduced from a photograph of a Jenny Lind which was on the Midland Railway. We are indebted for the photograph to Mr. Johnson. In May, 1848, it was decided that a competitive trial should take place between a Jenny Lind and another engine. The Midland locomotive chosen was built by Messrs. Sharpe, Stewart, and Co., and was known as the Jenny Sharpe. The following table gives particulars of the two engines:—

	Jenny Lind.	Jenny Sharpe.
Tubes	No. 124, 2in., 11ft. long ...	No. 161, 2in., 10ft. long
Surface	720 square feet	847 square feet
Fire-box	80 square feet	72 square feet
Total surface ...	800 square feet	919 square feet
Cylinder	15in. by 20in.	16in. by 20in.
Driving wheels	6ft.	5ft. 6in.
Weight loaded	24 tons 1 cwt.	21 tons 9 cwt.
Weight, tender	15 tons 13 cwt.	12 tons 11 cwt.
Total	39 tons 14 cwt.	34 tons
Load, 9 coaches 2 vans	64 tons	64 tons
Total load ...	103 tons 14 cwt.	98 tons

Average rise of road from Derby for 20 miles, 1 in 330
" " " " " " down, 1 in 330

The trip was from Derby to Masbro' and back. The trial took place on May 8th, 1848. The first run was made with the Jenny Sharpe. The average speed throughout was 49 miles per hour; up 1 in 330 it was 43 miles per hour. The total coke used, including getting up steam, was 16 cwt., or 44·8 lb. per mile; water evaporated, 10,290 lb., or 257 lb. per mile, and 5·7 lb. per pound of coke; pressure, 80 lb.; time of running, 50 min. 10½ sec. The next day, May 9th, the Jenny Lind made the same trip. Average speed throughout, 52 miles per hour; up 18 miles of 1 in 330 it was 47 miles per hour; total coke, including lighting, was 13 cwt., or 36·4 per mile; steam pressure, 120 lb.; time running, 46 min. 32 sec. The highest speed reached was 59 miles per hour. The highest speed reached by the Jenny Sharpe was 58·5 miles per hour. Two runs were then made with heavier loads, the total for the Jenny Lind being 139 tons 10 cwt., and for the Jenny Sharpe 133 tons 16 cwt. The total consumption was 13 cwt. by the first and 16 cwt. by the latter, the consumption per mile being 33·6 lb. for the Jenny Lind and 44·8 lb. for the Jenny Sharpe. The average speed of the former up 1 in 330 was 41 miles per hour, and for the latter 39·3 miles. Here was very conclusive evidence in favour of the higher pressure.

In a succeediug issue we shall give sections of the Jenny Lind. We have said enough, we think, to substantiate our statement that the type is one of unusual historical interest.

THE THEORY OF THE LUBRICATION OF PLAIN PARALLEL SURFACES.

By R. M. DEELEY, F.G.S., and C. E. WOLFF, B.Sc.

WITH the appearance of the paper by Prof. Osborne Reynolds, "On the Theory of Lubrication,"[*] may be said to date our knowledge of the action of viscous substances to diminish friction between relatively moving surfaces. Not that experiments had not previously been made. As a matter of fact, a vast amount of experimental data had been accumulated, but the results not only failed to agree among themselves, but also failed to agree with the general experience of engineers. The experiments of Mr. Beauchamp Tower, however, undertaken at the instance of the Institution of Mechanical Engineers, have served to explain the causes of most of these discrepancies. He found that much, very much, depended upon the way in which the lubricant was applied to the bearing, the friction depending upon the quantity and uniformity of the supply and distribution of the oil. Most of his recorded experiments were made in such a manner that the lubrication was what he called "perfect," *i.e.*, there was a comparatively thick film of oil maintained under pressure between the surfaces. When this was the case his results were strictly comparative, agreed better with the frictional resistances met with in such complex machines as steam engines, and were closely in agreement with hydrodynamical theory.

The theoretical results obtained by Professor Osborne Reynolds were published before Mr. Tower's experiments on collar friction and pivot friction were made. Professor Osborne Reynolds accordingly dealt with surfaces which, although they might be parallel under some circumstances, were not so when the loads were varied. On this account the friction was, generally speaking, in a great measure independent of the load, the mean thickness of the lubricating film remaining practically constant. The later experiments by Mr. Beauchamp Tower, however, were made on collar friction and pivot friction. In these experiments, although the faces were free to move to or from each other, they were constrained to remain parallel. Under these conditions there was a marked increase in the frictional resistance when the loads were increased; and to explain the facts it appears to us that some modification, or rather addition to, the theory is required.

In the present paper we hope to be able to show that the experimental results Mr. Tower obtained with plane parallel surfaces, and perfect lubrication, are also in agreement with theory. We will also discuss his experiments on collar friction. In them the rate of supply of the lubricant was so limited that the laws of solid friction were simulated.

Perfect lubrication.—We will, in the first place, discuss the theoretical aspect of the question, and then compare the theory with the experimental results. Fig. 1 shows two parallel planes of unlimited length and breadth, separated by a film of viscous liquid of thickness r. The upper plane C D is supposed to be fixed, while the lower plane A B moves in the direction of the arrow with a velocity V_1. By the definition of viscosity there will be a tangential resistance

$$F = \mu \frac{V_1}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

whilst the total resistance

$$R = \mu \frac{V_1 A}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where A is the area of the lubricated surface. The tangential motion of the fluid will vary uniformly from V_1 at A B to zero at C D. Thus, if F G—Fig. 1—be taken to represent V_1, then P N will represent the velocity of the fluid at P. To produce these conditions of motion the planes must have been in uniform motion for a sufficiently long period for the effects of inertia to have disappeared. When the surface C D is of finite extent, and A B is covered by a fluid, the effects of inertia persist; for fresh fluid is always approaching the fixed plane. In Fig. 2 the surface C D is of limited length, both parallel with and in a direction perpendicular to the paper. A B is flooded with oil. The oil at a distance from D is all moving at the speed V_1 of the plane A B. Before reaching the upper fixed plane, however, it feels the influence of the fixed end D of the upper plate, and some relative motion or distortion of the fluid is produced. At D the oil touching the plane is at rest, but instead of passing along between the surfaces—as in Fig. 1—in such a manner that the rate of distortion is everywhere the same, the momentum of the oil causes it to enter the space between the planes, so that the rate of distortion is much greater near the plane C D than it is near the plane A B; whilst at the end C the rate of distortion is approximately the same at all planes. In this case the lines E G are curved, and the areas enclosed, E F G, give the volumes passed at each section. It will be noticed that the areas at the entrance D are larger than those at the exit C, the excess of liquid escaping laterally owing to the small width of the plane C D in a direction perpendicular to the surface of the paper. When the planes are of large area, and are close together, the viscosity of the oil powerfully resists its escape at all points, and at the same time, by tending to make the rates of distortion equal at all points, causes the oil to accumulate and force the planes apart until the forces are in equilibrium. In this way, even when the opposing surfaces are parallel, a *pressure film* is maintained, and a considerable load may be supported by C D as long as A B is in motion. The resistance to the motion of the lower plane is then wholly due to the viscosity of the liquid film.

FIG. 1

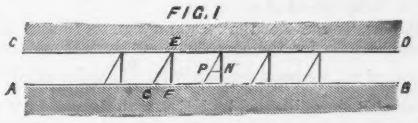


FIG. 2

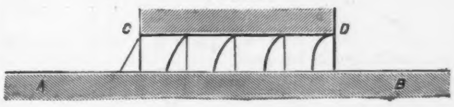

FIG. 3

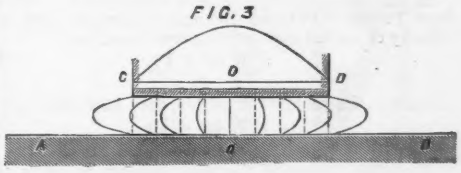

We will, in the first place, attempt to indicate the conditions determining the volume v_1, introduced owing to the relative motion of the surfaces and the density of the liquid. The liquid—resting upon A B at points distant from the surface C D—is moving with a velocity V_1. At the point D it is thrown against the opening between the surfaces, much in the same way as water from the combining cone of an injector is thrown against the orifice of the delivery cone. Its power of entering is proportionate to the square of the velocity, and almost independent of its viscosity; for the oil or water by its adherence to C D resists the entrance of the liquid just as much as its adherence to A B assists its entrance. The volume entering, however, is not quite independent of the viscosity, for the greater the viscosity the more the liquid on entering, especially at low speeds, will approximate to the steady state of flow. When the energy is not sufficient to enable the liquid to overcome the pressure, no liquid gets between the surfaces, which then close together and may seize. On the other hand, when the liquid does enter, the volume entering is proportionate to

$$V_1 \; r \; b = v_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

r being the distance between the surfaces and b the length of the orifice. The conditions attending the flow of the escaping fluid may be well illustrated by taking the case of parallel surfaces approaching each other without tangential motion. The fluid has to be squeezed out from between the surfaces; and since there is no motion at the surfaces, the horizontal velocity will be greatest half way between the surfaces—Fig. 3[†]—nothing at O the middle of C D, and greatest at the ends. This is for planes of infinite length in a direction perpendicular to the paper. If in a certain state of motion—shown by the dotted lines in Fig. 3—the space between A B and C D be divided into ten equal parts by vertical lines, and if these lines be supposed to move with the fluid, they will shortly after assume the positions on the curved lines, in which the areas included betwen each pair of curved lines is the same as in the dotted figure. If it were not for the inertia of the fluid these lines would be —as they are approximately—parabolas. It is at once seen that the curved lines indicate the rates of distortion at different points, and, as force is required to maintain the rate of distortion constant, a vertical pressure, W, must be applied to force the liquid out. The pressure will be greatest at O and fall off towards the ends C and D, and would be approximately represented by the curve at the top of the figure. The volume discharged has been found by Professor Osborne Reynolds to be, for circular plates, in unit of time

---

[*] "Transactions" Royal Society, 1886, page 157.

[†] Osborne Reynolds' "Transactions," Royal Society, 1886, p. 173

$$v = \frac{r^3 \mathrm{W}}{\mu a^4} k_1 \quad . \ . \ . \ . \ . \ . \ . \ . \ . \quad (4)$$

We will first consider the case of a bearing of infinite width and of length a in the direction of motion and loaded with a pressure W per unit of width. In this case, if the surfaces be supposed to approach without tangential motion, keeping parallel to one another, we shall have the volume v escaping

$$= \frac{r^3 \mathrm{W}}{\mu a^2} k \quad . \ . \ . \ . \ . \ . \ . \ . \ . \ . \quad (5)$$

the only difference between this and the case of a circle being in the value of the numerical coefficients. If we suppose the planes to be moving tangentially with a relative velocity V_1, the inflowing volume of oil will be proportional to $\mathrm{V}_1 \, r$, and must equal the quantity escaping.

We may, therefore, write

$$\mathrm{V}_1 \, r = k \frac{r^3 \mathrm{W}}{\mu a^2} \quad . \ . \ . \ . \ . \ . \ . \ . \quad (6)$$

$$\therefore \mathrm{V}_1 = k \frac{r^2 \mathrm{W}}{\mu a^2} \quad . \ . \ . \ . \ . \ . \ . \ . \quad (7)$$

$$\therefore \frac{\mathrm{V}_1^2 \mu^2 a^2}{r^2} = k \, \mathrm{V}_1 \, \mu \, \mathrm{W} \quad . \ . \ . \ . \ . \quad (8)$$

Now the total force R required to maintain the plates in steady motion is inversely proportional to r and directly proportional to $\mathrm{V}_1 \, \mu \, a$,

$$\therefore \frac{\mathrm{R}^2}{\mathrm{V}_1 \mu \mathrm{W}} \text{ is a constant, } \mathrm{C}^2 \text{ say,}$$

so that

$$\frac{\mathrm{R}}{\sqrt{\mathrm{V}_1 \mu \mathrm{W}}} = \mathrm{C} \ . \ . \ . \ . \ . \ . \ . \ . \ . \quad (9)$$

$$\text{and } \mathrm{R} \propto \sqrt{\mathrm{V}_1 \, \mu \, \mathrm{W}} \ . \ . \ . \ . \ . \ . \ (10)$$

and is independent of a.

If, now, we consider the case of a plane of limited width b, and assume for the moment that there is no lateral escape of oil, we must replace W by $\frac{\mathrm{W}}{b}$ and multiply the value of R thus obtained by b, *i.e.*, with the weight W distributed over b units of breadth, the resistance per unit breadth

$$= \frac{\mathrm{R}}{b} = c \sqrt{\mathrm{V}_1 \, \mu \frac{\mathrm{W}}{b}} \ . \ . \ . \ . \ . \ (11)$$

$$\therefore \mathrm{R} = c \sqrt{\mathrm{V}_1 \, \mu \, \mathrm{W} \, b} \ . \ . \ . \ . \ . \ (12)$$

and coefficient of friction

$$= \frac{\mathrm{R}}{\mathrm{W}} = \mathrm{C} \sqrt{\frac{\mathrm{V}_1, \mu b}{\mathrm{W}}} \quad . \ . \ . \ . \quad (13)$$

In the case of an ellipse of semi axes a and b, it follows from Professor Osborne Reynolds' equations that the velocity of normal approach is proportional to

$$\frac{r^3 \mathrm{W} (a^2 + b^2)}{a^2 \ b^2 \ \mu}$$

Therefore, the volume escaping, v, may he written

$$\mathrm{R} \frac{r^3 \mathrm{W} (a^2 + b^2)}{a^2 \ b^2 \ \mu}.$$

From this we get in the same manner as above (11) and (12)

$$\mathrm{R} = \mathrm{C}^1 \sqrt{\frac{\mathrm{V}_1 \ \mathrm{W} \, (a^2 + b^2) \, \mu}{b}} \quad . \ . \quad (14)$$

which in the case of the circle when $a = b$ reduces to

$$\mathrm{R} = \mathrm{C}^{11} \sqrt{\mathrm{V}_1 \, \mathrm{W} \, \mu \, b} \quad . \ . \ . \ . \quad (15)$$

The constant and, therefore, the values of R and the coefficient of friction, will vary with variations in the shape of the boundary of the surface, but is constant for surfaces of similar shapes. Hence, in the case of the ellipse, circle, and rectangle, we see that for similar-shaped surfaces the friction varies as the fourth root of the area of the surfaces.

The only experiments with which we can compare these theoretical results are those described in the fourth report of the Research Committee of the Institution of Mechanical Engineers on Friction.[*] In it are given the results Mr. Beauchamp Tower obtained with pivot friction. The pivot experimented with was of steel, had a perfectly flat end 3in. in diameter, and was pressed against a manganese bronze bearing in such a manner that the faces, although they could separate, were always parallel to one another. Fig. 4 shows the form of bearing used in these experiments. The bearing B formed a guide for the footstep, which fitted it loosely. The lubricant was supplied through a hole in the centre of the bearing, and was distributed by two radial grooves extending from the centre hole to within $\frac{1}{16}$in. of the periphery of the bearing surface. These two grooves were opposite each other, so that they lay on the same diameter. When the footstep was rotated the bearing rapidly took oil out of the supply pipe, and delivered it at the circumference of the bearing. It was then collected in an annular chamber surrounding the footstep, and returned to the centre by means of a small overflow pipe. The bearing therefore acted as a most efficient pump, causing a rapid circulation of oil through itself.

Before being used the surfaces were carefully made plane, and the machine allowed to run for a few hours. At first the oil came out dirty, showing that the surfaces were abrading each other slightly. As long as this continued the oil was run to waste, fresh clean oil being supplied to the centre. It was then allowed to run into the lubricating pipe, and the bearing became self-lubricating, continually using the same oil over and over again. The bearings were now completely separated by an oil film introduced from the two grooves by the motion of the footstep, and squeezed out again at other points by the pressure forcing the surfaces together. Although every care was taken to measure the friction between the surfaces, and to keep them in good condition, no attempt was made to ascertain the temperature of the bearing, or the viscosity of the oil used. Some resistance to motion must also have been offered by the oil film surrounding the cylindrical portion of the footstep; but, as the clearance is not given, and we do not know the viscosity of the oil, its magnitude cannot be calculated. We are, consequently, neither able to compare one experiment quite satisfactorily with another, nor yet to estimate with perfect accuracy the effects produced by varying speeds, for it would appear that the experiments made at each particular speed were made on different days at different temperatures, and probably with different samples of oil.

Assuming that the oil did not vary throughout the trials, and as the experiments were made with the same footstep and bearing, we may write from (9)

$$\mathrm{C} = \mathrm{R} \sqrt{\frac{1}{\mathrm{N} \ \mathrm{W}}} \ . \ . \ . \ . \ . \ . \ . \ . \quad (16)$$

N being the number of revolutions of the footstep per minute.

In Tables I., II., III., IV., and V., the values of C are given along with the speed, the load, and the frictional resistance. At low speeds with increasing loads C increases steadily, showing that the oil film is not keeping the surfaces properly apart, and that at this speed we are dealing with a very thin film and imperfect lubrication. At the higher speeds, however, C actually decreases somewhat until the heaviest loads are reached. It then increases with increasing loads. The decrease is probably partly brought about by the heating effect of the friction decreasing the viscosity of the lubricant, or it may be due to the fact that the force measured was partly due to the viscous resistance of the oil film surrounding the footstep. This would be proportional to the speed. The subsequent increase in the value of the constant in Tables II., III., IV., and V. we may regard as being due to the fact that the increasing load has made the film so thin that it cannot properly be called a pressure film.

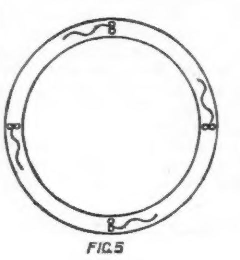

FIG. 5

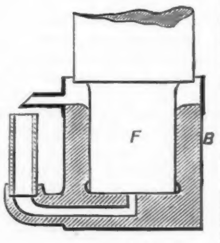

FIG. 4

Imperfect lubrication.—The only other reliable experiments on the friction of plain parallel surfaces are those on collar friction, also carried out by Mr. Tower[†] for the Institution of Mechanical Engineers. The lubrication, however, was imperfect. In these experiments the turning moment on a steel ring of rectangular section pressed between two gun-metal surfaces was measured. The annular bearing surfaces of the discs were 12in. inside diameter and 14in. outside diameter, giving on each disc an area of exactly 40 square inches, after deducting the oil channels. The method of lubrication adopted was one which is in practical use for collar bearings. It consisted of four grooves—see Fig. 5—cut in each face of the ring, ¼in. wide and ¾in. long, arranged in a diametrical direction, and so that each end of the grooves was ⅛in. inside the grooves of the bearing surface. From each of these grooves there extended in the direction of motion of the surfaces a shallow groove about $\frac{1}{10}$in. wide, and of a serpentine form, tapering away to nothing in about 3½in. length. These grooves were supplied by pipes into which the lubricant was dropped at carefully regulated rates. The magnitude of the friction depended considerably upon the rate of lubrication; but a minimum rate of lubrication was soon found with which the bearing would work safely, such that if the lubrication was less the bearing would show signs of seizing by rapid variations of friction and by a jerking of the lever; and if it was much more the friction, though less, was not reduced in proportion to the increase of the oil supply. The rate at which the oil was used varied from 60 drops to 120 drops per minute, the quantity varying with the speed and load. In the case of perfectly lubricated surfaces we found that the rate at which the oil was taken in between the surfaces was proportional to $\mathrm{V}_1 r$, being as much as the bearing could take. In the collar bearing experiments, however, the supply was limited, only just sufficient oil being used to prevent seizing, *i.e.*, rupturing the film. As the friction was found to be approximately independent of the speed, the film must have been allowed to increase in thickness at a rate proportional to the speed. It must also have had a thickuess inversely proportional to the load, on the assumption that we are dealing with fluid friction. Regarding it as a case of fluid friction, in which the film is of just sufficient thickness to prevent seizing, we find

$$c = \frac{\mathrm{R}}{\mathrm{W}} \ . \ . \ . \ . \ . \ . \ . \ . \ . \ . \quad (17)$$

and is independent of N. This formula merely expresses the experimental results. In this way the value of the constant c in Tables VI. to IX. have been calculated.

From the formula

$$c = \frac{\mathrm{R}}{\mathrm{W}}$$

we may obtain another showing how the quantity of oil supplied varied, as compared to the quantity the bearing could have taken with perfect lubrication. As we are only dealing with one particular bearing, the variation of the friction with the dimensions may be neglected, and we get

$$c = \frac{\mathrm{R}}{\mathrm{W}}$$

and

$$\mathrm{R} \propto \frac{\mu \mathrm{V}_1}{r} \quad . \ . \ . \ . \ . \ . \ . \ . \ . \ . \quad (18)$$

$$\therefore \frac{\mu \mathrm{V}_1}{r \mathrm{W}} \text{ is constant}$$

$$\therefore \mathrm{V}_1 = k \frac{r \mathrm{W}}{\mu} \quad . \ . \ . \ . \ . \ . \ . \ . \quad (19)$$

and

$$k \frac{r^3 \mathrm{W}}{\mu} = \mathrm{V}_1 \, r^2 \quad . \ . \ . \ . \ . \ . \ . \ . \quad (20)$$

$k \frac{r^3 \mathrm{W}}{\mu}$ is proportional to the quantity the bearing would require for perfect lubrication. Consequently the oil supplied varied at a rate proportional to $\mathrm{V} \, r^2$ instead of $\mathrm{V} \, r$, in these experiments. And this rate of supply, according to Mr. Tower, was just sufficient to prevent seizing. In Table I., showing the results obtained with perfect lubrication at a low speed, C increases greatly with increase of load. Here the speed is not sufficient to carry in the oil, and we have imperfect lubrication. On this account we have added the values of c, which it will be seen are much less variable.

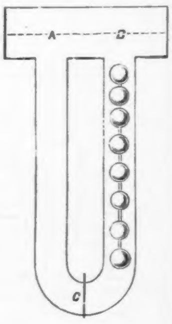
CIRCULATION IN WATER-TUBE BOILERS.

THE literature of water-tube boilers has attained respectable proportions. It is at once precise and comprehensive. The conclusions arrived at by its authors are usually dogmatic—a fact which would save the student much trouble were it not for the circumstance that no two authorities agree. Just now we shall not concern ourselves, however, with anything save the phenomena of circulation in such boilers. We are about to place before our readers particulars of a series of most instructive experiments carried out by Mr. Yarrow. But it is necessary in the first instance to clear the ground, and explain the questions which it has been Mr. Yarrow's object to decide.

To shallow minds, circulation in a water-tube boiler presents no difficulties; to the physicist and the engineer the matter is one of considerable perplexity. We must, at the risk of being wearisome, go over old ground and write once more that which has often been written already.

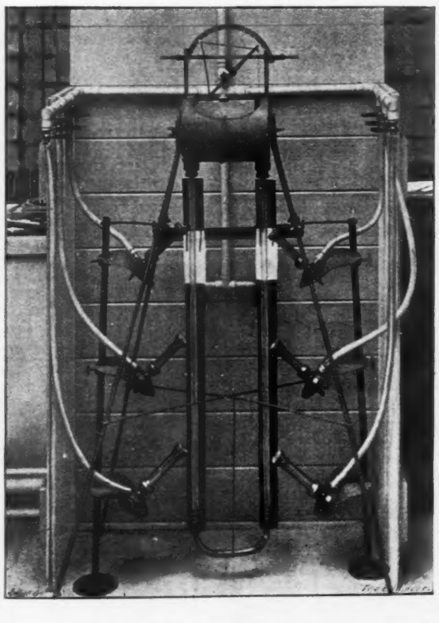
If water is heated in a U tube, it will rise in one leg and fall in the other, because the water in the heated leg expands, becomes lighter, and a given height of column will no longer balance a column of the same height in the other leg of the tube. An excellent illustration is supplied by nearly filling a U tube with water, and then cautiously pouring alcohol down one leg. It will be found that the column of alcohol and water is longer than the column of water alone. All this is plain sailing. When, however, the water has all been heated to the boiling point, and there is no longer a difference of temperature, how is circulation maintained? It is at this point that the two contending parties separate. The first party holds that the ascending leg containing steam and water, the column in it must be lighter than that in the descending or cold leg because that contains water alone. To which the opposing party reply that such reasoning reminds them of that of the boy who, being asked why bread and butter always falls butter side down, said that it was because that side was the heavier, for there was only bread at one side of the slice and bread and butter on the other side. Now we have already in the course of a series of articles on water-tube boilers, published in Vol. lxxvi. of THE ENGINEER, explained that under certain circumstances both parties are right. If the tube be so small in diameter that the bubbles of steam fill its cross section, fitting it like a piston, then the contents of the ascending leg will be both really and hydraulically lighter than the solid water in the descending leg. If, however, the bubbles are too small to fit the tube, then circulation cannot be produced by the difference in the actual weight of water in the tubes, because the hydraulic head is not affected. As this proposition has been strongly controverted, and, as we believe, because those who hold it to be unsound have failed to understand it, we may be excused for stopping here to put the facts before our readers. In B let us place a solid rod C. It is obvious that the weight of water in B will then be less than the weight of water in A; but, for reasons familiar to everyone with an elementary knowledge of hydrostatics, no circulation will ensue. But it may be urged that bubbles are not a solid rod. Let us then turn down our solid rod until it assumes the form shown in the sketch, and still the result will be the same. Nor would the effect be modified in any way if the rod was replaced by a string of balls continually drawn up through the tube in so far as they would secure that the column B was ligdter than the column A. But the rising of the balls, or of bubbles of steam, would cause circulation in quite another way by entraining water in B and dragging it along with them. We shall show presently that the result of a most remarkable experiment could not have been what it was if the bubbles really caused a difference of hydraulic head at opposite sides of the line C in the sketch. Circulation is due, then, when the bubbles are smaller in diameter than the tube, to a much more subtle cause or causes. The one is the continual cutting-off of the top of the column of the water at the surface by the escape of the bubbles; the other is the skin friction of the bubble entraining water; and the third is the piston-like action due to the approximate fit of the bubble in the tube. What, we may ask, is a bubble of steam or air? What is the condition of the water forming its sides? There is every reason to believe that the bubble wall is in a state of tension, and that a strict analogy exists between it and the walls of a soap bubble. As to the actual method of the formation of a steam bubble, of course no one knows anything in a proper scientific way.



So much said, we may go on, and add that wide diversities of opinion exist as to how circulation may be best secured in a water-tube boiler. Discussions on this point would fill volumes, and they are principally remarkable for the persistence with which opinions are advocated which have no real foundation in ascertained fact. We are constantly told that such and such a thing must take place; all the while no proof based on direct experiment is advanced of its soundness. Among all the things about which the world has been positive, about nothing has it has been more positive than that in all boilers cold places are essential to secure circulation. In the water-tube boiler especially downpipes or feeders have been freely adopted, and it has been asserted in the most positive and obtrusive fashion that they cannot be dispensed with. Now Mr. Yarrow in the first of his water-tube boilers, going with popular opinion, fitted four cold "downcomers," one at each end of the two tube chambers. After a time it was found that these down pipes were very much in the way in small craft, and so two of them were left out without any evil results. Then the other two were taken out, and again nothing happened. Delighted to find that the boilers took care of themselves without downcomers, Mr. Yarrow next proceeded to ascertain what really happened. For a considerable time he has been carrying out experiments at the Isle of Dogs with great elaboration and much outlay, and on Saturday last he invited to the works a large party of gentlemen interested in such questions, and showed them his experiments, which, it is proper to add here, all succeeded, notwithstanding that some of them are very delicate.

We cannot do better than reproduce here a descriptive paper written by Mr. Yarrow, a copy of which was handed to each one of his visitors. But, in the first instance, we wish to direct particular attention to two experiments which are of the greatest importance, namely experiments 1 and 5. The first shows what is at the first glance apparently incredible, namely, that a brisk circulation can go on in a U tube, heat being applied to the down side. The experiment moreover taught a lesson which is seldom demonstrated to the eye in a very clear way. Bubbles of steam were freely formed in the down pipe. They were carried downwards by the current, and as they descended they grew smaller and smaller, and finally disappeared. We have here an admirable object-lesson. Every student of Clark-Maxwell knows that if we compress steam isothermally it will liquefy, and that nothing but sufficient water is needed to secure the isothermal condition. There is, of course, plenty of water present here, but every student does not realise how small is the amount of compression which will produce liquefaction. The disappearance of the bubbles, their reappearance in the rising tube, and the great increase in the volume of steam produced, were eminently instructive. The lesson conveyed by Experiment No. 5 is, however, probably of more practical utility. Mr. Yarrow in his paper scarcely does it full justice. We have here three tubes. Calling the two rising pipes A and B, a rush first takes place up A, and a down rush through B. Then the phenomena reversed; the water and steam rose in B, and water descended in A, and this operation went on with much regularity. Each time a rush occurred water was thrown out of the upper receiver. Here, in fact, was priming pure and simple. When the downcomer was heated also, the current steadily ascended in both the rising tubes, and all priming ceased.

Fig. 1



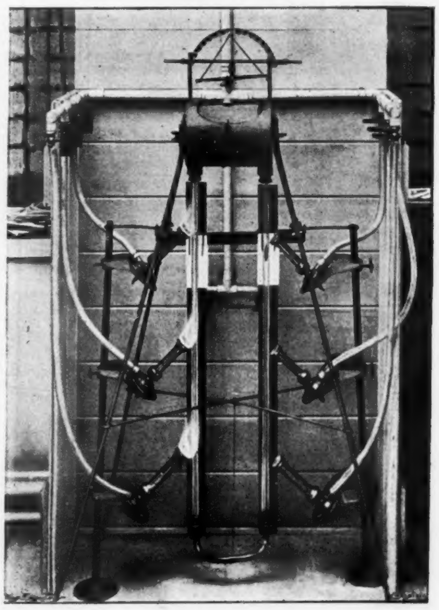
A multitude of deductions may be drawn from these experiments. We shall content ourselves with one for the present. Experiment No. 8 Mr. Yarrow stated was very delicate, the propellers requiring to be adjusted with extreme care, otherwise they would not revolve. It is to the credit of those who carried out the details that the propellers spun merrily on Saturday. The fact remains that the water circulation in any boiler depends on very small forces. A trifling obstruction in a tube will prevent circulation altogether. Given a clear way, and the water will course at high speed through the tubes, but block the road and the water stops. The circulation is produced by the equivalent of a small difference of head. It is quite sufficient for all purposes, but the flow of the water must not be impeded in any way. The straight tubes of the Yarrow boiler are just what is wanted. Another point which must not be overlooked is that the circulation largely depends, it would seem, for its efficiency on momentum. Start it which way we please in a U tube and it will continue. This is in itself proof that the circulating force is very small. The great lesson taught is that so long as the water is left a free way and is not hampered in any fashion, a water-tube boiler will take very good care of itself. A not less important lesson is the complement of this. It is that small interferences with freedom of circulation may readily bring about disaster. Experiment No. 1 showed the importance of keeping an equal pressure in all the tubes. Thus, if one riser out of a dozen was exposed to a little higher pressure than its fellows it would probably become a downcomer, or might work in gulps and get burned. Our readers will not be slow, we fancy, to draw other lessons. One they cannot miss. It is that the community of engineers is indebted to Mr. Yarrow for throwing light into dark places, and for so freely imparting information that he has only obtained for himself by a great outlay of time, and skill, and money.

Mr. Yarrow's paper runs as follows:—

Description of Experiments made at Messrs. Yarrow and Co.'s Works, Poplar, January 4th, 1896.

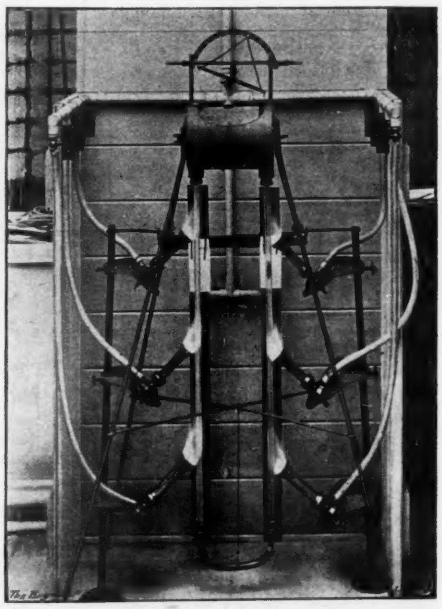
With a view to throw light on the circulation of water in water-tube boilers, Messrs. Yarrow and Co. have carried out numerous experiments, and considering that the results obtained would be of interest to engineers at the present moment, they determined to make them public. One point which these experiments prove is that the heating of down tubes actually accelerates the circulation and does not retard it, as is generally believed.

Fig. 2



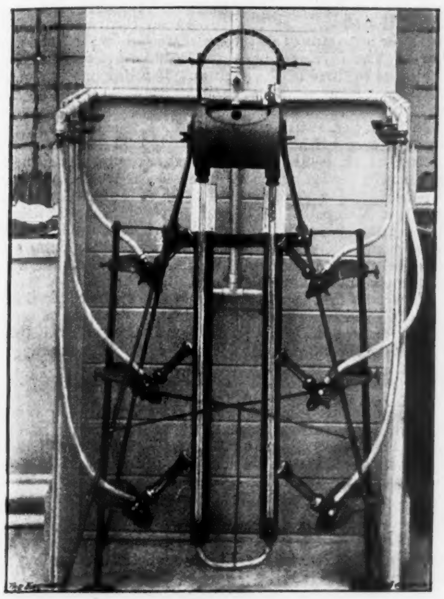
Experiment No. 1 is illustrated by Figs. 1, 2, and 3, which represent the same model under different conditions. This model consists of two vertical glass tubes attached to the bottom of a small tank, the tubes being united at their lower extremities by a copper bend. There are six Bunsen burners, three acting on each tube, and arranged so that they can be regulated at will. On the upper part of the model is a balance, one arm of which is suitably loaded, and from the other arm is, hung by a thread, a grooved ebony bob, which is suspended in the down tube in such a manner that the water when flowing downwards, acting on the bob, causes it to descend, depressing the end of the balance to which it is attached. Fig. 1 represents the model in its normal condition, before any heat is applied; Fig. 2 shows the effect when three lamps on the up tube are lit; and Fig. 3 illustrates the result when the three lamps on the down tube are lit in addition to the three acting on the up tube. This experiment does not indicate the speed of the current, but it shows very clearly any increase or decrease in the speed of the descending column of water, that is to say, the rapidity of the circulation. When the pointer is vertical, it is at zero; when it moves over towards the up tube side the figures are indicated as minus; when it moves towards the down tube side the figures are indicated as plus. The following are the results of carefully tried experiments:—When no heat was applied, the pointer indicated —45, as represented in Fig. 1. When only one lamp was acting on the up tube, the current was too intermittent to record a reliable result. When two lamps were acting on the up tube, the pointer indicated —12. When three lamps were acting on the up tube, the pointer indicated —5, as repre-

Fig. 3



sented by Fig. 2. When three lamps were acting on the up tube and one on the down tube, the pointer indicated + 10. When three lamps were acting on the up tube and two on the down tube, the pointer indicated + 15. When three lamps were acting on each side, as shown in Fig. 3, the pointer indicated + 20.

Fig. 4



These experiments clearly prove that the circulation gradually increased as more and more heat was applied, irrespective of the proportion of the total heat absorbed by the up and down tube. Further experiments showed that, within certain limits, the rapidity of the circulation depended solely upon the total amount of heat applied, irrespective of how this heat was divided between the descending and ascending columns.

Fig. 5

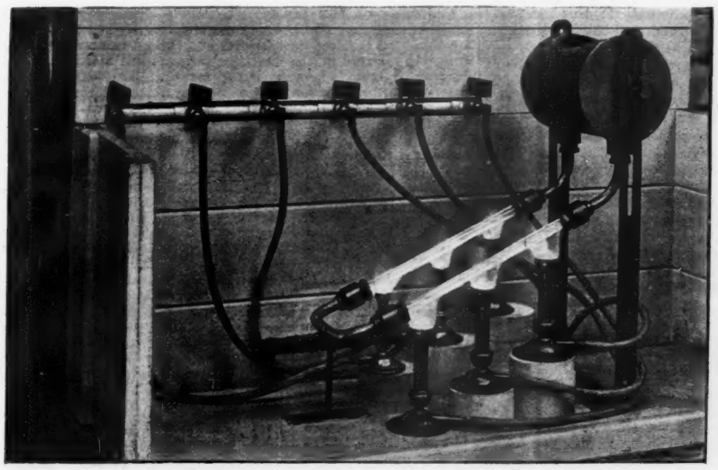


Fig. 6

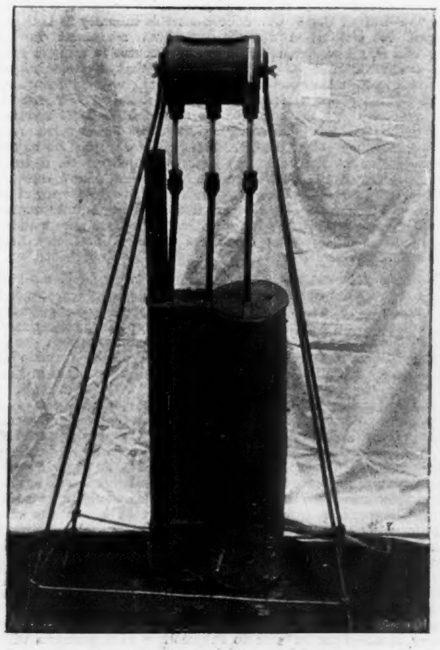
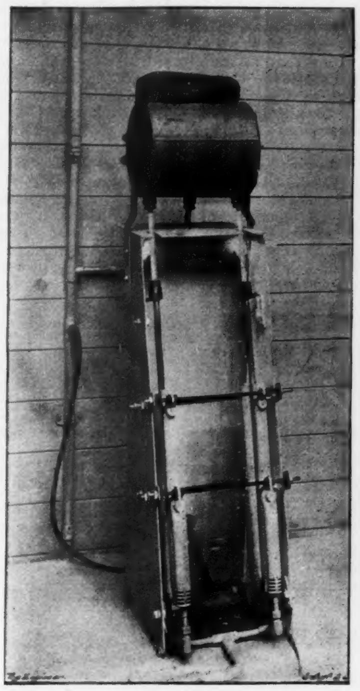


Experiment No. 2 is illustrated by a similar model, Fig. 4. In the down tube is placed a small screw propeller, which, when revolving, actuates a vertical spindle, having at its upper end a worm, gearing into a small worm-wheel, as will be seen. This arrangement was made at the suggestion of Mr. Maxim, and it enables the speed of the current, under varying conditions, to be estimated. When two lamps were acting on the up tube the speed recorded by the propeller was found to be 28ft. per minute. When three lamps were acting on the up tube the speed was 36ft. per minute. When three lamps were acting on the up tube and one on the down tube the speed was found to be 42ft. per minute. When three lamps were acting on the up tube and two on the down tube the speed was 49ft. per minute. When three lamps were acting on the up tube and three on the down tube the speed was 55ft. per minute.

Fig. 7



These experiments confirm those previously described with the suspended bob, proving a gradual increase of speed in the circulating system as more and more heat was applied, irrespective of whether this heat was absorbed by the water in the up tube, or by the water in the down tube. It should be remembered that, owing to the resistance offered to the flow of water by the screw, the actual speeds, if no screw had been there, would have been greater than those above recorded. In addition to this, an allowance must be made for the slip of the screw. It must be borne in mind that in all the foregoing experiments circulation must have been set up by heat being first applied to the up current, which in all water-tube boilers is the case, those tubes nearest the fire being heated first, and thus circulation is established. These experiments also illustrated what has not yet, we believe, been referred to, viz., that any bubbles of steam formed in a descending column rapidly disappear; and it is more than probable that in a down tube moderately heated no steam whatever is formed, because as the current descends, the temperature of the water can rise without producing steam owing to the increased head of water and the higher temperature of the boiling point at the greater pressure. For example: under atmospheric pressure the water in the upper part of a tube would boil at 212 deg.; but the water in the lower part of the tube, if 4ft. long, would boil at 218½ deg.; consequently the whole body of water can be raised from 212 deg. to 218½ deg. while descending without producing any steam. This heat, thus absorbed, is given off by the conversion of a portion of the water into steam as the current ascends in the up-tube. In the experiment the bubbles could be clearly seen forming where the flames impinged, and, as they descended, to disappear, the steam parting with its heat and raising the temperature of the surrounding water.

Fig. 8

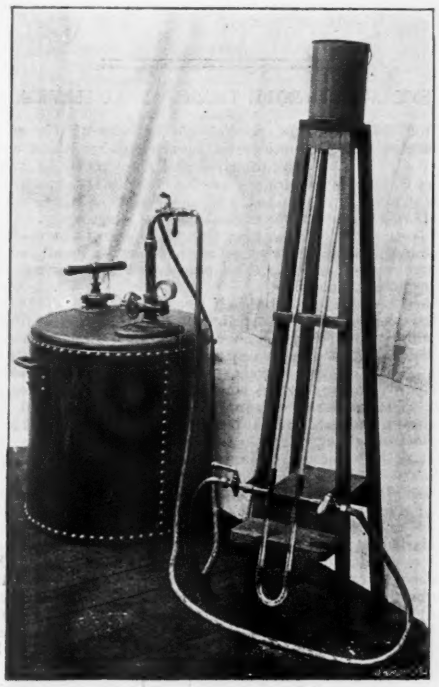


Fig. 9

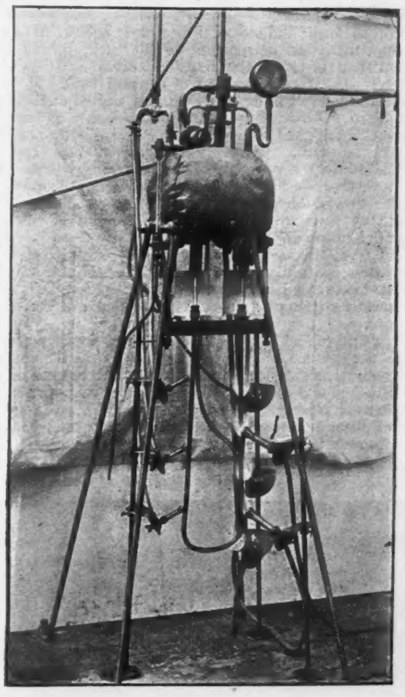
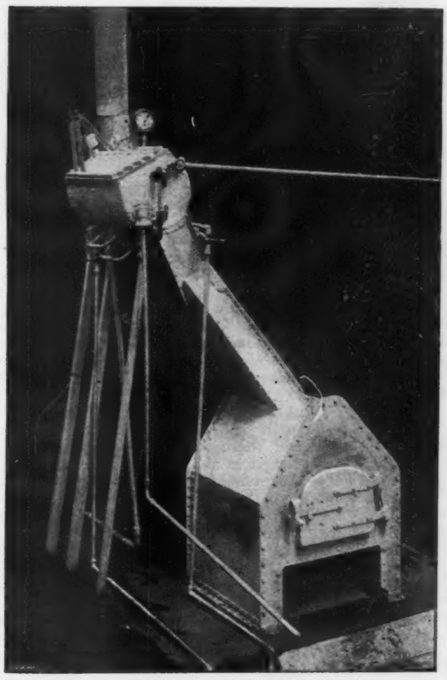


Experiment No. 3 was illustrated by a model, Fig. 5, consisting of two glass tubes, placed at a small angle to the horizontal, their upper ends being connected to a small cistern and their lower ends united. The tube on one side was arranged to be heated by three Bunsen flames and the other tube also by three Bunsen flames of smaller size. When once the circulation was started in the up tube by the three larger flames, those acting on the down tube could also be lit and the circulation could be clearly seen to be accelerated.

Fig. 10



Experiment No. 4 consisted of a cistern, Fig. 6, from the bottom of which were led three tubes, the lower portions of which were of copper and the upper portions of glass. The three copper tubes were united at their lower extremities, being secured to a horizontal chamber. They were all situated in a gas furnace, lined with asbestos, heat being applied directly to the tube on the one side by means of several multiple Bunsen burners, the flames from which passed across the other two tubes and up the funnel which is seen in the photograph. This experiment more nearly approaches the condition of an ordinary Yarrow water-tube boiler, and it was seen that sometimes there were two down currents in the two cooler tubes, and one up current in the tube most heated, and at other times there were two up tubes and one down tube. In this model as much as 9 lb. of water per square foot of heating surface was evaporated.

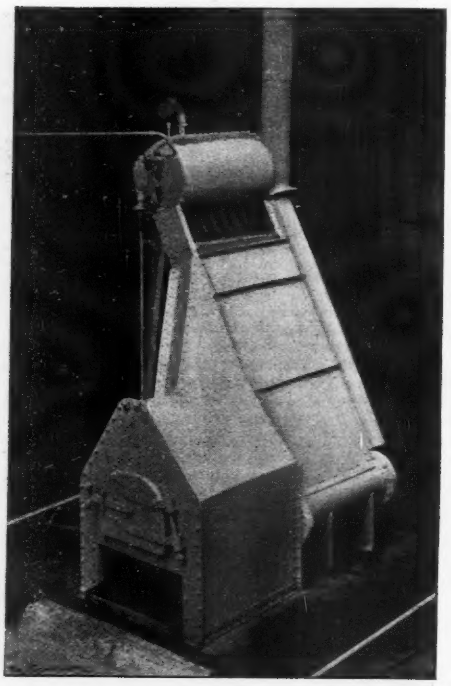
Experiment No. 5 consisted of two glass tubes, Fig. 7, projecting from a small tank, the tubes being nearly vertical. These glass tubes were united to copper tubes, at the bottom of these was a **T**-piece, to which a third tube of copper was connected, the upper extremity of which was secured to the bottom of the tank. The two composite glass and copper tubes were in front and the copper tube was at the back, this latter representing an outside down pipe. Multiple Bunsen burners were provided for heating all three tubes. On heating the two front tubes an up current was established in both, the copper tube at the back serving as an outside down pipe, and the speed of the current could be seen by watching the flow of water and steam in the glass tubes. When heat was applied to the downcomer at the back, it was clearly evident that the circulation was accelerated.

Experiment No. 6 consisted of a small tank, Fig. 8, from which were led two inclined glass tubes, united at their lower extremities. Provision was made to introduce a current of air from an air tank under pressure into either or both these tubes, as will be seen. When upward circulation had been established in the one tube, by introducing bubbles of air, then a further supply of air was admitted into the down tube, which air passed downwards with the water and then upwards in the up current, increasing the circulation, which was maintained even after the supply of air had been completely cut off from the tube containing the ascending column, the circulation continuing in the same direction, air only being admitted into the down tube.

All the foregoing experiments were made at atmospheric pressure.

Experiment No. 7 showed the action under a pressure of 150 lb. per square inch. It will be seen that at the upper part of the model, Fig. 9, is a steam chest, to the bottom of which was attached a **U** tube, fitted with glass at its upper extremities, so as to render the circulation visible. There were three small Bunsen lamps in connection with the one leg, and five large Bunsen lamps in connection with the other leg. It was found that if the circulation was once established by lighting the three small Bunsen flames on the one side, producing an up current on that side, then the five large flames on the down current might be started, increasing the circulation, which actually continued after the three flames in the up tube were all turned out. This extreme condition under which circulation can be maintained, we venture to say, is one which few engineers would believe possible, and confirms the views expressed by Professor Lambert and Mr. Maxim.

Fig. 11



Experiment No. 8, Fig. 10, was made on a full-size section of a water-tube boiler with straight tubes, working at a high pressure. At one end there was a furnace under forced draught by means of a jet in the funnel. The flame passed transversely across the group of tubes to the funnel, situated at the end opposite to the furnace. In the tube furthest removed from the furnace was placed a small screw propeller, and also a similar fitting in the third tube from the end, by which the direction of the current and its minimum speed could be estimated. On raising steam and forcing the fire the propellers were seen to revolve in a direction indicating a steady down current in either one or both of the tubes in which the propellers were introduced, previous experiments proving that a down current existed in the second tube from the end. It was found that there were never less than two down tubes in operation.

Experiment No. 9, Fig. 11, represented also a full-size section of a water-tube boiler having straight tubes, heated in the same manner as in the former case. The circulation was rendered visible by the upper part of the tubes being of glass. It could be clearly seen that an upward current was established in those tubes nearest the fire, water descending in those which were furthest removed from it, confirming the previous experiment.

It may here be remarked that the maximum evaporation obtained by Messrs. Yarrow and Co. when the circulation had been forced to a very high pitch, was 25 lb. of water per square foot of heating surface, but this being an uneconomical amount of forcing, is far beyond the range of what is desirable in practice.

Experiment No. 7 clearly proved that circulation was more efficiently maintained at a high than at a low pressure, it being found that the extreme condition of maintaining circulation by applying heat only to the down pipe was never certain, except with pressures over 50 lb. per square inch; between 30 lb. and 50 lb. this result was doubtful, and below 30 lb. it was not possible. The reason of this is probably due to the reduced velocity of the down current in the case of low pressures, owing to the greater bulk of a given weight of steam at low than at high pressures, all of which steam has to pass through the up tube; or in other words, there is less resistance to a given weight of water and steam at a high pressure flowing through a system of tubes than at a low pressure, on account of the lesser bulk of the water and steam in the former case. The exact arrangement of the propellers in connection with No. 8 experiment is seen by the sketch, Fig. 12, showing a section through the steam chest and one of the tubes containing the propellers. In order to obtain reliable data as regards the temperature of the tubes, which are exposed to the fiercest action of the fire, the following facts in connection with No. 8 experiment will be instructive, and to fully explain, reference must be made to the section, Fig. 13, through the tube nearest the fire. The lower end of a long rod was attached to the water chamber at the bottom, this rod passing up through the centre of the tube and thence through the top of the steam chest. At the upper end of this rod was a pointer, and a similar pointer was affixed to the steam chest itself, as will be seen, the two pointers being exactly in a line with one another. Thus, whatever difference in the relative lengths of the tube and the rod took place, it would be at once made evident by alterations in the position of the pointers in relation to one another. If thus the tube, owing to its being exposed to great heat, expanded more than the rod, it could at once be detected, and any such increased relative length would be an indication of an increased relative temperature. Now it was found that there was no visible difference in position between the two pointers, whether the fire was forced or extinguished, and as the rod passing up through the steam and water would have a temperature equal to that of the steam and water, it follows that the temperature of the tube is the same, or the difference, if any, is so trifling as not to be indicated by the means above described.

Fig. 12

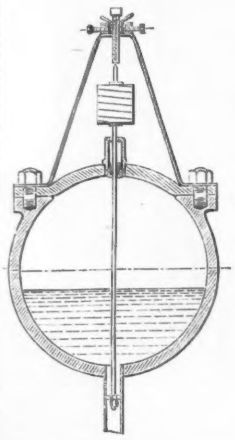


Fig. 13

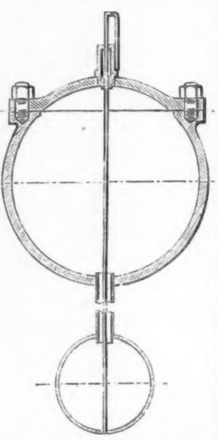

This experiment conclusively proves that, so long as there is good circulation, no possible objection can exist to the adoption of straight tubes, as in a Yarrow boiler, owing to imagined necessity to allow for variations in length, due to differences of temperature. For all practical purposes, the temperature of all the tubes may be considered the same as that of the water they contain, in the same manner as in an ordinary marine or locomotive boiler, in which no special provision is made for differences in expansion of the tubes, although they are by no means all exposed to the same extent to the action of the heated gases. This experiment, which is confirmed by practical experience in the use of the Yarrow boiler, points conclusively to the fact that the curving of tubes in water-tube boilers—having good circulation—for the sake of allowing for variations in length due to variation of temperature, is quite unnecessary.

STEAM AND ROPE TRAMWAY AT HAVRE.

The older business portion of the city of Havre is connected with the residential suburb on the inland cliff, about a mile back from the river, and from 200ft. to 250ft. above it, by inclined streets unsuited for ordinary omnibuses, so that in order to establish a regular means of communication, some system of mechanical traction is necessary. This has been done by combining the principles of the balance incline with steam traction, on a plan shown in detail in our contemporary, *Le Genie Civil*, whence we have derived the following particulars.

The line, which is about half a mile in length—750 m.—is extremely crooked, the straight line distance between the terminal points being only about 500 yards, and the difference in height 230ft. For nearly two-thirds of the length it is laid along existing streets, the remaining part, about 300 yards, being carried in a curved tunnel in the chalk cliff. The gradients vary from 1 in 14½ to 1 in 9, and the minimum radius of curvature is 164ft. The line, which is single throughout, with the exception of a short crossing place at the lower end of the tunnel, is constructed like an ordinary cable line with an enclosed iron channel for the rope between the rails, with an open slot for the gripper, but the latter is only a rod projecting from the bottom of the car, to which one end of the rope is fixed, the other end being similarly attached to the second car. The line is worked as an incline without intermediate stoppages, the weight of the descending car contributing part of the power necessary for the ascent of the opposite one, which is, however, mainly effected by steam, so that the function of the rope is merely to tie the cars together. The descending car runs entirely without steam except in case of need, when it may be used in counter pressure.

The cars, which are intended to carry fifty passengers—twenty seated in a central compartment, and thirty standing in an outer covered platform—are carried on two axles, giving a rigid wheel base of 7ft. 3in., while the total length is 32ft., the platform for the outside passengers overhanging 12ft., and that at the opposite end which carries the boiler and feed pumps nearly 11ft. The boiler of the well-known Serpollet, weighing about two tons, has a heating surface of 87 square feet, with a maximum evaporating power of 1100 lb. per hour. It has been tested to 94 atmospheres, and has neither safety valve nor gauge glass. The working steam pressure is 15 atmospheres; the steam cylinders of 2⅜in. diameter and 5⅞in. stroke—60 mm. and 150 mm.—are placed outside the framing of the car between the axles, and drive the latter by means of an intermediate pinion shaft and pitch chains. The driving wheels, of 31½in. diameter, make one revolution to three of the engines. The link motion of the Waelschart form, as well as the brakes, are controlled by hand levers from the end platform. The connecting rope, made of extra quality cast steel wire of 108 tons tenacity, is 20 mm. in diameter, with an ultimate tensile resistance of 21 tons, which is fifteen times the maximum strain exerted by the fully loaded motor car when stopped on the steepest incline of 110 per 1000, or seven times that of two loaded cars pulling at both ends. It is run over 4¾in. grooved sheaves, placed 21ft. apart, and reverses over a 6½ft. pulley at the upper terminus, the ascending and descending lines being kept 8in. apart by another of the same size placed below and a little above to the reversing one.

The deadweight of the car is 9½ tons, or when fully loaded with fifty passengers, 13 tons, giving a resistance on the steepest incline of 110 per 1000. $13{,}000 \div 0{\cdot}11 = 1430$ kiloms., which for the maximum speed of 41m. per second gives $\frac{1430 \cdot 4}{75} = 76$-horse power as the necessary driving power.

At the steepest point of the road, however, the descending car is on a gradient of 80 per 1000, and supposing it to be empty the power exerted is $9500{\cdot}008 = 760$ kilos. in aid of the ascending load, and reducing the resistance of the latter to $1430 - 760 = 670$ kilos. Adding to the 150 kilos. for the friction of the rope, the necessary engine power becomes $\frac{(670 + 150) \cdot 4}{75} = 43{\cdot}7$-horse power, showing a saving of about 30 per cent. in power by the use of the connecting rope between the two cars.

Trade and Business Announcements.—Mr. B. H. Thwaite, F.C.S., A.M.I.C.E., announces that he has opened an office at 29, Great George-street, S.W.—Messrs, Isles, Limited, Steam Crane Works, Stanningley, near Leeds, have appointed Mr. H. Grunwell, M.I.C.E., as their agent in London for steam and hand cranes.—Messrs. W. F. Dennis and Co., inform us that they are removing to 23, Billiter-street, E.C.

Explosion on the Irish Mail Train.—When the Irish mail which left Euston on Wednesday morning at 7.15, had travelled to a point a few hundred yards north of Watford Station, a terrific explosion occurred in the luncheon car. At the moment of the occurrence breakfast was being served. The extraordinary event naturally caused not a little commotion amongst the passengers. Their apprehensions were increased as the train dashed into a tunnel, and for the moment the compartment was in darkness. Moreover, the report was followed by a large burst of flame, and repeated showers of red hot cinders from the boiler end of the coach, the burning portions of coal, and copious quantities of water covered the three travellers, and added to their alarm, which was not lessened when the carriage was fired by the falling ashes. The flames were, however, speedily extinguished, but it was impossible to pull the communication cord until the exit from the tunnel had been made. It was ascertained that a third of the saloon had been completely shattered, and the passengers were impressed with their marvellous escape. The train was brought to a standstill at King's Langley, and the occupants of the wrecked car were then transferred. The explosion is said to have had its origin in the cooking apparatus, but nothing definite is known as to the actual cause. The report was heard throughout the length of the train. The train was carefully examined at Boxmoor, where the wrecked car was left, and the train, being uninjured, was allowed to proceed to Holyhead.

Admirable.—It is the established policy of this journal to take no part in the discussion of purely political or partisan questions. But the results of the public discussion of such questions often become proper topics for consideration here. During the last ten days the possibility of a war with England has been precipitated upon the country, and in the excitement which greeted the President's message and some of the inflammatory speeches in Congress, very many things were said, and reached publicity in the daily Press, which had far better have been left unsaid. The stock-market panic which followed has at this writing apparently spent its force; and the indications are, that a wiser and more moderate temper is prevailing in the consideration of the questions in dispute on the part of both countries. War between England and the United States would be a terrible calamity to both, and indeed to civilisation itself. The best sentiment in both countries is, we believe, opposed to any recourse to arms to settle diplomatic differences. It is fortunate that the course now decided upon makes necessary a considerable delay before any more serious action can be taken; and it is to be hoped that during this delay the conservative sentiment in both countries may make itself felt in no uncertain way. So far as mere money matters are concerned, either nation could well afford to buy the whole of Venezuela a half dozen times over and present it to the other, rather than enter upon the uncertainties and enormous outlays of war. The humanitarian and economic aspect of the question must appeal also to every thinking man, and no words of condemnation can be too strong for those who from pure malice or from motives of cupidity seek to fan the flame of international discord.—*Engineering News.*

More Water-tube Boilers.—Although very little sea-going experience with water-tube boilers has been gained since their introduction into the service, the Admiralty appear to be determined to give them an all-round trial. Following in quick succession orders for these boilers of various designs were given for the Speedy, Sharpshooter, Spanker, and several of the torpedo boat destroyers. Then the Powerful and Terrible were taken in hand, and before the Sharpshooter had been fitted with Belleville boilers it was decided to supply the same type to the new vessels. Since then water-tube boilers have been approved for first and second-class cruisers, and it was concluded that the Admiralty would still provide locomotive boilers for battleships and torpedo boats. Only a few days ago, however, it was arranged that No. 80 torpedo boat at Devonport should have water-tube boilers, and since then it has been decided to remove the boilers from the cruiser Bellona, now attached to the Channel Squadron, and replace them with those of the water-tube type. The vessel will be removed from the Channel Squadron for this purpose after the next cruise. Her present boilers have not given satisfaction. The Bellona is only four years old, and although she has done very little sea service her boilers are reported to be considerably worn. The crowns of the combustion chambers of two of the boilers are bulged considerably, and although the vessel's efficiency may not be impaired up to a limited steaming power, it would not be wise to subject her to a pressure which, with other vessels, might be safely done. The cruiser Proserpine, building at Sheerness, is also to be supplied with water-tube boilers. It is stated that the Thornycroft type will be adopted in her case, and the boilers, together with the propelling machinery, will be made at Keyham Factory.—*Western Morning News.*

RAILWAY MATTERS.

Mr. Thomas Henry Ellis has succeeded Mr. C. S. Dennis as district passenger superintendent, at Darlington, for the North-Eastern Railway.

A verbatim report of the conference on light railways, held at the Westminster Palace Hotel on November 28th, has been issued by Messrs. Eyre and Spottiswoode.

It is said that some of the engines Messrs. Neilson and Co. are about to construct for the Midland Railway Company will have very large boilers and tanks. More boiler and more water would make the run from Nottingham to Carlisle possible without a stop.

The mail train which left Johannesburg on the evening of the 30th ult. for Durban, crowded with passengers, left the rails and was completely overturned while running past a sharp curve between Dannhausen and Glencoe, on the Natal line. The disaster was of a terrible character. Thirty-seven persons were killed and fifty others were injured, many of them dangerously.

When referring in our annual article last week to the Lancashire, Derbyshire, and East Coast Railway, on page 14, we stated that Messrs. Pearson and Son were the contractors for this line. This is true so far as Contracts 1 and 2—Chesterfield to Warsop and Beighton Branch—are concerned, but we find that Contract 3—Warsop to Tuxford—is let to Messrs. Baldry and Yerburgh, and Contract 4—Tuxford to Lincoln—to Messrs. Price and Wells.

The bill seeking powers to construct a tramway from Derby to Ashbourne, of which mention has already been made in The Engineer, has now been deposited in Parliament. It is for the construction of a single line commencing by a junction on the present lines of the Derby Tramways Company, and terminating at Ashbourne. The capital is put down at £70,000, divided into 7000 shares of £10 each. Under clause 31 of the Bill the cars must be moved by animal power. Application is to be made for the consent of the Board of Trade to the use of the overhead trolley system of electrical traction. The line is to be constructed within five years.

The locomotive driving tires in general use on the Great Eastern Railway are made of Bessemer steel, having a tensile strength of 40 tons per square inch, and the following composition:—Combined carbon, 0·350 per cent.; silicon, 0·083 per cent.; sulphur, 0·064 per cent.; phosphorus, 0·047 per cent.; manganese, 0·605 per cent.; iron—by differences—98·851 per cent. The wear on the tires of some six-wheeled coupled suburban engines in severe service was such that only 2197 miles was obtained per $\frac{1}{32}$in. reduction in thickness, the tires being 4ft. diameter. Consequently seventeen of these engines were fitted in January, 1892, with special hard steel tires, having a tensile strength of 48 tons to the square inch, and the results obtained up to their first turning were satisfactory. The average mileage was 47,134 for an amount of wear equal to $\frac{1}{4}$in. in thickness, or 5892 miles per $\frac{1}{32}$in. reduction.

Of the 364 tires which failed on our railways during the nine months ending September last, 15 were engine tires, 6 were tender tires, 3 were coach tires, 13 were van tires, and 327 were wagon tires; of the wagons, 249 belonged to owners other than the railway companies; 217 tires were made of iron, and 152 of steel; 10 of the tires were fastened to the wheel by Gibson's patent method; 9 by Mansell's patent method, 2 of which left their wheels when they failed; 2 by Beattie's patent method; 269 by bolts or rivets, 1 of which left the wheel when it failed; 72 by other methods, 1 of which left the wheel when it failed; and in 2 cases the method of fastening was not stated; 38 tires broke at rivet holes, 128 in the solid, and 198 split longitudinally or bulged. This very large excess of breakages through the solid is a further confirmation of the theory of the fracture of these tires given in the paper on the subject in the "Proceedings" of the Institution of Civil Engineers, vol. xlvii.

While the use of electrically welded rails in Boston has not been an entire success, some 6 per cent. of the joints breaking during the first winter they were in use, it appears from a valuable paper read before the Engineers' Club of St. Louis that in that city a great measure of success has been attained. Mr. Robert McCulloch, the author of the paper, states that of 2203 electrically welded joints on 3$\frac{1}{4}$ miles of double track in St. Louis, 72 joints or 3·27 per cent. have broken. Thirty-seven broke during the cold weather of the first part of last winter, and each was repaired by casting a mass of iron, around the broken part, a portable furnace being employed to melt the iron. During the second cold snap later in the same winter, 35 more breaks occurred, which have not yet been repaired. Seven of the joints opened nearly 2in. on breaking, while in others the crack was barely perceptible; the average amount of opening was about $\frac{1}{4}$in. During the warm weather of the past summer these cracks closed a trifle, but the amount of the movement was unimportant.

Under the new Bill for the East to West Railway, which has duly been deposited, the Derbyshire and East Coast Railway are applying for power to construct four branch railways and one deviation line, which will be comprised in their Chesterfield and Lincoln separate undertaking, for which powers were granted in 1895. The new lines are made up as follows:—Two branches in Nottinghamshire of a length of 1 mile 6 furlongs 6 chains, known as the Shirebrook branch; a short line in Derbyshire known as Cresswell branch; another line to the Colliery Railway of the Warsop Main Colliery, and another to the lines of the Barlborough Colliery. The deviation set forth in the new Bill is at Tuxford. It will begin by a junction with the company's line at Great North End, and finish by another junction with the Great Northern Railway at Tuxford Station. In addition to the above powers the company seek authority to make further access to their Langwith Junction Station, to purchase more land at Boughton, Warsop, and Sookholme in Nottingham, and Upper Langwith, and near Duckmanton Station in Derbyshire.

In reporting on the buffer-stop collision on November 27th, at London Bridge Station, on the London, Brighton, and South Coast Railway, when seven passengers are reported to have been shaken, the Board of Trade inspector says: "This slight collision with buffer-stops was due, as is now usually the case, to an error of judgment on the part of the driver of the train. If drivers would make it a rule to stop, at least, one carriage length away from the ends of terminal platforms or any obstruction on a platform line, and thus give themselves more margin than they do under present circumstances, a slight miscalculation would not necessarily involve a collision. Injuries to several persons are the almost invariable result of even the slightest buffer-stop collision, owing to the fact that passengers are usually standing up in the act of getting out of the carriages or collecting their things. The acceleration of speed referred to by the driver and fireman as having occurred just when the train should have stopped may have been due to either of two causes, viz.:—(1) The rails are said to have been rather wet, and the fireman in applying his hand-brake with full force to stop the train may have caused the wheels to 'skid,' and thus give the impression of the engine receiving fresh impetus; or (2) the guard's brakes may, as the driver suggests, have been released at that moment. The conversation which passed later in the day between the driver and guard certainly goes to show that the brakes on the rear van had not been applied with anything like full force previous to the collision; that guard's evidence as to the rebound of the train also tends in the same direction. However this may be, the train appears to have been well in hand as it ran alongside the platform; and, as I have said above, the driver must take the responsibility for not seeing that it was brought to a stand before it reached the buffer-stops."

NOTES AND MEMORANDA.

Last week's return of births and deaths in London and in thirty-two other great towns, states that the deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 20·7 per thousand of their aggregate population, which is estimated at 10,860,971 persons in the middle of this year.

In a paper on the direct combination of nitrogen with metals, M. A. Rossel in the *Comptes Rendus* states that it has been found that if an intimate mixture of finely-powdered calcium carbide with magnesium powder is heated with free access of air, the metal is almost completely transformed into the nitride. Finely divided aluminium, zinc, iron, and copper act similarly.

In London 2735 births and 1707 deaths were registered last week. Allowing for increase of population, the births were 220, and the deaths 523, below the average numbers in corresponding weeks of the last ten years. The annual death-rate per 1000 from all causes, which had been 17·5, 18·1, and 17·8 in the preceding three weeks, rose again last week to 20·1. During the four weeks ending on Saturday last the death-rate averaged 18·4 per 1000, being 5·4 per 1000 below the mean rate in the corresponding periods of the ten years 1886–95, the mild weather being unusually favourable.

Strong glass plates are bored through by means of rotating brass tubes of the necessary diameter, which are filled with water during boring. To the water there is added finely pulverised emery. Thinner glass can be perforated with holes in an easier manner by pressing a disc of wet clay upon the glass and making a hole through the clay of the width desired, so that the glass is laid bare here. Then molten lead is poured into the hole and lead and glass drop down at once. This method is based upon the quick, local heating of the glass, whereby it obtains a circular crack, the outline of which corresponds to the outline of the hole made in the clay. The cutting of glass tubes, cylinders, &c., in the factories is based upon the same principle.

A paper on "The Expansion of Argon and of Helium as compared with that of Air and Hydrogen" was recently read before the Royal Society by Dr. J. P. Kuenen and Dr. W. W. Randall. The gas-thermometer used for these experiments was such as could be easily heated by means of a "Ramsay and Young" vapour jacket. It consisted of a bulb sealed on to a capillary tube, which in turn was sealed on to a wider tube, provided with a mark. This mark is situated just outside the heating arrangement, immediately below the capillary tube. The inner mercury surface is made to coincide with this mark, and both this one and the outer surface are read on a scale with a telescope. The readings were duly corrected for capillary action, expansion of glass and mercury, and the part of the gas that is not heated. The results show that up to 240 deg. C., the highest temperature that was employed, the expansion of both argon and helium is very nearly the same as that of air and hydrogen.

A new heavy liquid has been discovered. Mr. S. L. Penfield describes its preparation in the December number of the *American Journal of Science.* Mix equal proportions of the nitrate of silver and thallium, and on heating the mixture it fuses at 75 deg. C., forming a clear mobile liquid of density 4·5, which mixes with water in all proportions. It can therefore be used to separate mineral particles of densities below 4·5. When still heavier particles have to be separated, the proportion of thallium may be increased. When the ratio is 3 : 4 the mixture fuses below 100 deg. C. and has a density of about 4·7 At 2 : 4 the fusing point becomes 150 deg. C., and the density 4·8; at 1 : 4 it is about 4·9, and fusion only takes place at 200 deg. Finally, when pure thallium nitrate is used, the point of fusion is 250 deg. C., and the density closely approaches 5. This high range of densities, together with the fact that the salts do not, *Nature* says, attack many minerals, make the liquid especially valuable for mineralogical purposes.

At the meeting of the Paris Academy of Sciences on the 23rd ult., the president announced that a biennial prize—20,000f.—which is in rotation in the gift of each of the five Academies, and which this year fell to the Academy of Sciences, has been awarded to M. Raoult for his discovery of the numerical relations between the molecular weight of a substance and the lowering of the freezing point and vapour pressure of its solvent. The other prizes were awarded as follows:—The Francœur prize to M. J. Andrade, the Poncelet prize to M. G. Robin, for his contributions to mathematical physics. In mechanics, the extraordinary prize of 6000f. was divided between M. Mottez—2500f.—for his work on the correction of ships' compasses; M. Houette—1500f.—for his aids to navigation; M. Gosselin—1500f.—for his method of studying the velocity of projectiles; and M. Baucher—500f.—for his study of the action of sea water upon metals. The Montyon prize was given to M. Galliot, for a new application of electric traction on canals; and the Plumey prize to MM. Pollard and Dudebout. The Fourneyron prize was divided between M. G. Marié and M. Lecornu, for their experimental and theoretical work on steam governors.

According to a paper on the temperature variation of the thermal conductivities of marble and slate, contributed to the *American Journal of Science* by B. O. Peirce and R. W. Willson, such a temperature variation does not exist; in other words, that marble and slate conduct heat equally well at all temperatures. The result is of some importance to the physics of the earth's crust, and the manner in which it was arrived at displays some ingenuity. Two faces of a slab of marble or slate were kept at different temperatures, and the fall of temperature between one surface and the other was determined by means of thermopiles. Now it is notoriously difficult to determine the temperature accurately at a certain point, and borings lead to errors in estimated depth. So the expedient was adopted of slicing the slab into a series of layers pressed together, between every two of which a thermocouple was introduced. The interstices were only a few tenths of a millimetre, and experiments with different intervals proved that the error in the temperatures observed did not exceed one or two degrees Centigrade. On plotting the temperatures and distances, the temperature was found to have fallen uniformly throughout the slab. If the conductivity had been higher at higher temperatures, the fall on the hot side would have been more decided. The temperatures ranged from 350 deg. C. to zero.

M. Osmond states that in highly carburised steels, containing more than 1·3 per cent. of carbon, quenched at temperatures above 1000 deg., there are two constituents, A and B, which differ widely in their properties. The constituent A is the ordinary, hard, strongly magnetic substance of which hardened steel containing 1 per cent. of carbon is almost exclusively composed. Its hardness is greater than that of orthoclase. B, on the other hand, is only about as hard as fluorspar, and, as far as can be judged by a study of its properties while mixed with A, is non-magnetic. M. Osmond, however, has been hitherto unable to prepare B free from A, although by quenching steel containing 1·6 per cent. of carbon at a temperature of from 1000 deg. to 1100 deg, in ice-cold water, he has obtained a mixture of A and B in about equal proportions. This mixture is comparatively very feebly magnetic. The constituents both contain carbon, and exist side by side in separate polyhedra. The author concludes that B is the allotropic form of iron—denoted γ—which is especially stable above 860 deg., and is present to the exclusion of the other forms of iron in steels containing 25 per cent. of nickel, or 12 to 13 per cent. of manganese, these steels being non-magnetic. *Nature* says the hard constituent A would then be the allotropic form β. The research will be hailed by the allotropists as affording most important evidence in favour of their theory.

MISCELLANEA.

The Science and Art Department has received through the Foreign-office a communication stating that an International Exhibition will be held in Brussels in 1897.

The full text of Mr. Chamberlain's recent despatch on the subject of trade between the United Kingdom and the Colonies, with the detailed list of commodities, is published, by direction of the Council, in the current issue of the *Journal* of the Royal Colonial Institute.

The Department of Science and Art has received through the Foreign-office a communication from her Majesty's Consul at Barcelona, stating that it is proposed to hold a Fine Art and Industrial Exhibition in that city, commencing on the 23rd April next.

The Leicester Corporation Waterworks Committee have, upon the recommendation of Mr. J. B. Everard, M.I.C.E., decided to adopt the system of electro-mechanical apparatus, invented and manufactured by Mr. George Jennings, Lambeth, London, to indicate and register between the new reservoirs and engine houses at Swithland, Hallgates, and Cropstone, the varying levels of water in the reservoirs.

We are informed that the Marine Department of the Board of Trade completed an extensive and exhaustive series of tests upon electrolytically formed seamless copper steam pipes made by Elmore's Patent Copper Depositing Co., Leeds, and as a result of which the Board of Trade inspectors have been instructed to pass this company's manufacture of steam pipes for use in passenger and other steamships built under Board of Trade survey.

The Admiralty have decided to maintain four of the new 27-knot torpedo boat destroyers in commission at Sheerness, for the instruction of engine-room men and the training of officers and seamen in the use of that type of vessel. Four are also to be kept in commission at Portsmouth, and a similar number at Plymouth; and it is the intention of the Admiralty to combine the twelve vessels annually for a series of exercises in the summer months.

With reference to the 113$\frac{1}{2}$ million tons of coal imported by France during the first nine months of 1895, and the excess of 113,490,000f. or £4,539,600 in value of coal exports over imports, the *Echo des Mines* observes that it is incomprehensible why the Government does not second the efforts of coalmasters, and concludes that "C'est sur l'Angleterre qu'il faut gagner à tout prix; c'est l'ennemi industriel. La Belgique reste comme la soupape de sureté."

A mill chimney collapsed on Saturday evening last at Burnley, resulting in the loss of three lives and serious damage to property. The chimney belonged to an old disused mill. It was built of rubble stone, and was about 60ft. high. Without any warning, it fell about seven o'clock, the bulk of the masonry falling on two shops, which were demolished. There were only five people in the two shops at the time, and three of these were killed, and the others seriously injured.

As we recently stated, an Electrical Lighting and Power Act has recently been passed at the Cape of Good Hope, authorising regulations for the safety of the public, and Mr. A. P. Trotter, B.A., M.I.C.E., Assoc. M. Inst. C.E., has been appointed Government electrician and inspector under it. On Monday evening a complimentary dinner was given at the Whitehall Club by about sixty of his friends, when the expression of their good wishes for his success in Africa was accompanied by a present of a handsome gold watch. Mr. Trotter leaves for Cape Town in a few days.

We are informed the Admiralty have accepted the tender of Sir John Jackson, of Westminster, for the construction of the Naval Docks at Keyham, Plymouth, which are to be proceeded with forthwith. The amount recently voted by Parliament towards the cost of these works is two millions sterling. The works will be carried out under the supervision of Major H. Pilkington, R.E., of the Admiralty, as chief engineer. Sir John Jackson is well known as at present carrying out the new harbour works at Dover.

A complete system of purifying atmosphere and regulating temperature is in operation at Chicago, for the switchboard room of the Telephone Company, where dust formerly interfered seriously with the connections on the switchboard. The air for the room is forced through a chamber, where it is thoroughly sprayed, then passed through rapidly rotating spiral coils, which strip it of superfluous moisture, and afterwards through a chamber kept at nearly uniform temperature by the use of ice or of heating apparatus, as may be required. Access to the switchboard room is through an ante-chamber, and the temperature of the room itself shows a variation of not more than two degrees in a month.

A special train arrived from Cardiff on the 5th inst. bringing a set of powerful pumps and the necessary boilers to begin work on the Cunard steamer Cephalonia. From other ports have come light railway wagons with plant for unloading and then raising the liner now stranded in the upper part of Holyhead Harbour. In addition, three steamers and a tender, accompanied by a powerful tugboat, are now grouped around her. The crews of the various steamers have been supplemented by some two hundred dock labourers, all of whom are engaged unloading and transferring her cargo to the several steamers. Powerful pumps are at work on the Cunarder, and as the water falls the goods released are immediately removed. As soon as space below is freed, divers will go down and endeavour to cover the holes in the torn plates, and when these are secured they will be covered with a strong solution of cement, to make her sufficiently seaworthy to be taken round to the Mersey. The rents in the bottom and sides of the great steamer are believed to be serious, judging from the quantity of water in her compartments, and it is considered remarkable that she remained afloat to reach Holyhead under the circumstances.

A remarkable and serious gas escape occurred in Lime-street, on Monday Police Constable Carter noticed a strong smell of gas opposite Nos. 24 and 27, and at once sent word to the gas company. Chief Inspector Wigley, with his assistant Mr. Stuvington, and a staff of workmen, were at once despatched to the spot, and there is no doubt that but for their prompt arrival a serious explosion would have occurred. The gas was cut off from the shops in the immediate vicinity, safety lamps being temporarily supplied by the company. Every precaution was also taken to prevent any contact between the gas and the electric light, a large number of men from the respective companies being on the spot. The work of breaking open the roadway to inspect the main was found to be very difficult owing to the heavy layer of concrete below the asphalte. During the operations a spark from the pickaxe of one of the men ignited the gas, the result being a tremendous blaze, which caused some commotion among those who witnessed it. The flame was eventually extinguished by being beaten with a sack. About three hours afterwards, however, the gas again became ignited, owing, it was supposed, to the same cause, and this being a more serious outbreak, it became necessary to communicate with the Fire Brigade, by whom the blaze was put out with the aid of one of the adjacent hydrants. It was not until after seven o'clock, the men having then been at work for about nine hours, that the fracture in the main was discovered, and it was then seen that the leakage had been caused by a heavy subsidence in the earth. The main where the breakage had occurred was resting on no foundation, and the subsidence was so large that a man could have crawled under.

DIAGRAM OF BETHLEHEM ARMOUR PLATE

Fig 1.

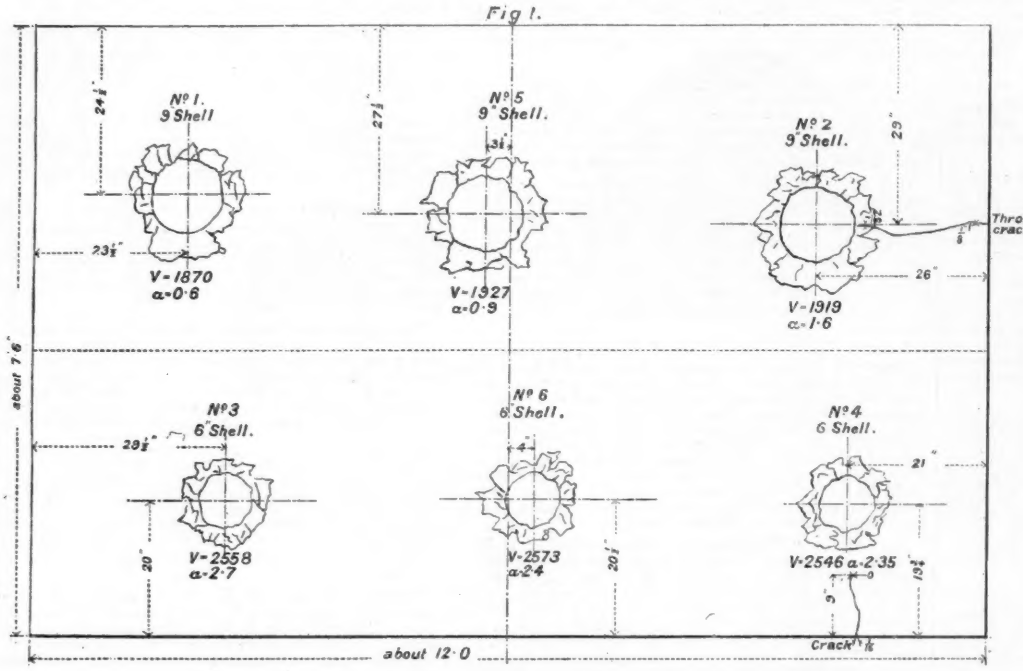

Fig 2.

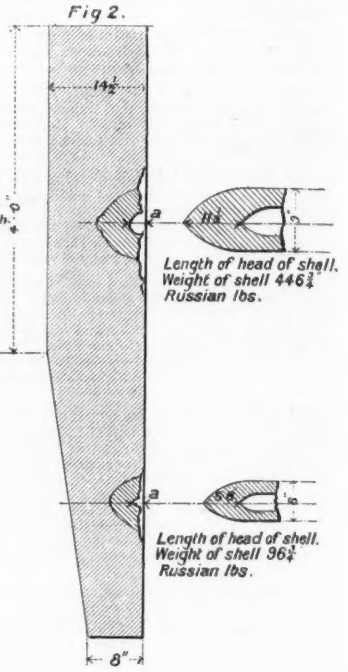


AMERICAN AND RUSSIAN ARMOUR TRIALS.

We have long considered that we need to exert ourselves in the matter of armour in this country if we do not wish to be left behind other Powers, and in this position England of all nations cannot afford to be, because armour is mainly employed on ships. Indeed, both in quantity and in importance, armour on coast forts and inland forts bears no comparison to that on ships, and moreover is in most cases of a different kind from that which we mainly consider, namely, steel armour with a treated face. Possibly our misgivings may appear to some unreasonable, and due to a restless tendency to find fault with what is English and praise what is foreign. England has grand establishments for manufacturing armour, and makes enormous quantities of excellent plates, and with such establishments and experience, and with larger interest in the question than any other Power, it does not seem probable that we should allow ourselves to drop seriously behind other nations. We trust that at present we are not yet seriously behind, but we believe that we shall soon become so if we do not take decided steps to prevent it. Our manufactures are excellent, but we have lately shown a want of enterprise in developing our armour. We will give our readers our conclusions, and the grounds on which we base them. At the present moment, in the United States and on the Continent, nickel steel armour has almost wholly come in. In this country, on the other hand, we have apparently given up nickel except in the thin plates used in the structure of ships and in deck armour. Next, the application of the Harvey process to thick armour, say 12in. thick and over, has received comparatively little attention. Our great class of armour battleships building, of which the Magnificent is the first, are covered with 9in. plates on their sides, and though they have some of 14in. thickness on their barbettes, we have practically satisfied ourselves that a 9in. treated steel plate, which is about equal to 18in. of wrought iron, is as much as is worth while carrying on our sides. For this there is no doubt reason, inasmuch as the system of curved deck combined with it provides a second defence for the vital parts of the ship. In fact, no one can question that the side protection is admirable so far as these particular ships are concerned. Nevertheless, the fact remains that all this has caused thick armour to receive comparatively little attention, and it has its uses even on the barbettes of these ships. In America during the past year a series of trials in proof of supply of plates up to 18in. thickness has developed the manufacture of excellent armour, which is already carried in large quantities on actual ships. This armour has, we believe, all the hardness that we can give in this country, combined with the toughness which can only be obtained from nickel.

We have fallen into giving up nickel, because we found at a comparatively early stage of the manufacture of treated plates that we experienced difficulties with it, and were able to make rather harder plates without it. At that time, for our immediate wants, there was much to be said for turning out plates without nickel. For cruisers especially, hardness is valuable, and it was an object to push on quickly with our ships; but it has, unfortunately, followed as a consequence that we have neglected nickel. Unfortunately, nickel costs money, and unless a very decided and immediate advantage was apparent in adopting it, it would not be likely to be adopted, and no such decided advantage could be obtained without experience. Other nations persevered with nickel, and have reaped the benefit. They have got over any difficulties attendant on after operations, due to the presence of nickel, and they have secured great hardness combined with the toughness characteristic of nickel. This, of course, is a statement easily made, but we think that it is supported by the results obtained in experiments.

To pass next to another point. "Double forging" has come in in the United States, and the recent "record breakers," as they call them, have chiefly been double forged plates of Carnegie's. So far as we know, double forging has not been publicly tried in this country, yet surely it is a very natural process to apply to plates which have been exposed to a very high temperature for several days, during which crystallisation may have taken place. When we say it has not been tried in this country, we do not mean that makers may not have tried it privately. It is possible that some of the plates tested in our Government trials may have been double forged. We know of no reason why this should not have been done, indeed we have recently heard that Mr. Ellis is shortly going to submit for trial some nickel plates, one of which is double forged, but double forging has not been tested publicly in this country as yet.

Finally, we believe that we are distinctly behind America in the manufacture of armour-piercing projectiles. For all these unpalatable statements evidence is needed, and must be carefully taken. If shot and plates are both improved, it is evident that the result of firing such shot against such plates may not be apparent. Superiority, indeed, might be easily claimed for both shot and plates while both were inferior. For this reason it is desirable to try the shot of others against our own plates, as we have done in the case of Holtzer, and occasionally other makers, but it is a practice that may too easily be discontinued. At all events in Holtzer's 6in. shot we have an excellent international standard, which is good as far as it goes, seeing that this particular calibre has established an excellent character which Holtzer's larger projectiles have yet to achieve. The 6in. shot is of no use for the thicker plates above referred to, but it applies, at all events, to the thinner ones, and enables an estimate to be formed of the powers of shot made in America. In this country a 6in. Holtzer projectile, with a sufficient velocity, say 2000 foot-seconds, will perforate any 6in. plate which we oppose to it, and has done so with lower velocity. In the States a really good 6in. treated and double forged plate is now expected to defeat 6in. Holtzer projectiles. We will pass, however, to our immediate object, which is to record the results of certain experiments in Russia and America. We attach special value to the results of Russian trials, because they are, so far as we have had the opportunity of witnessing them, admirably conducted, and French, English, and American plates get dealt with in turn.

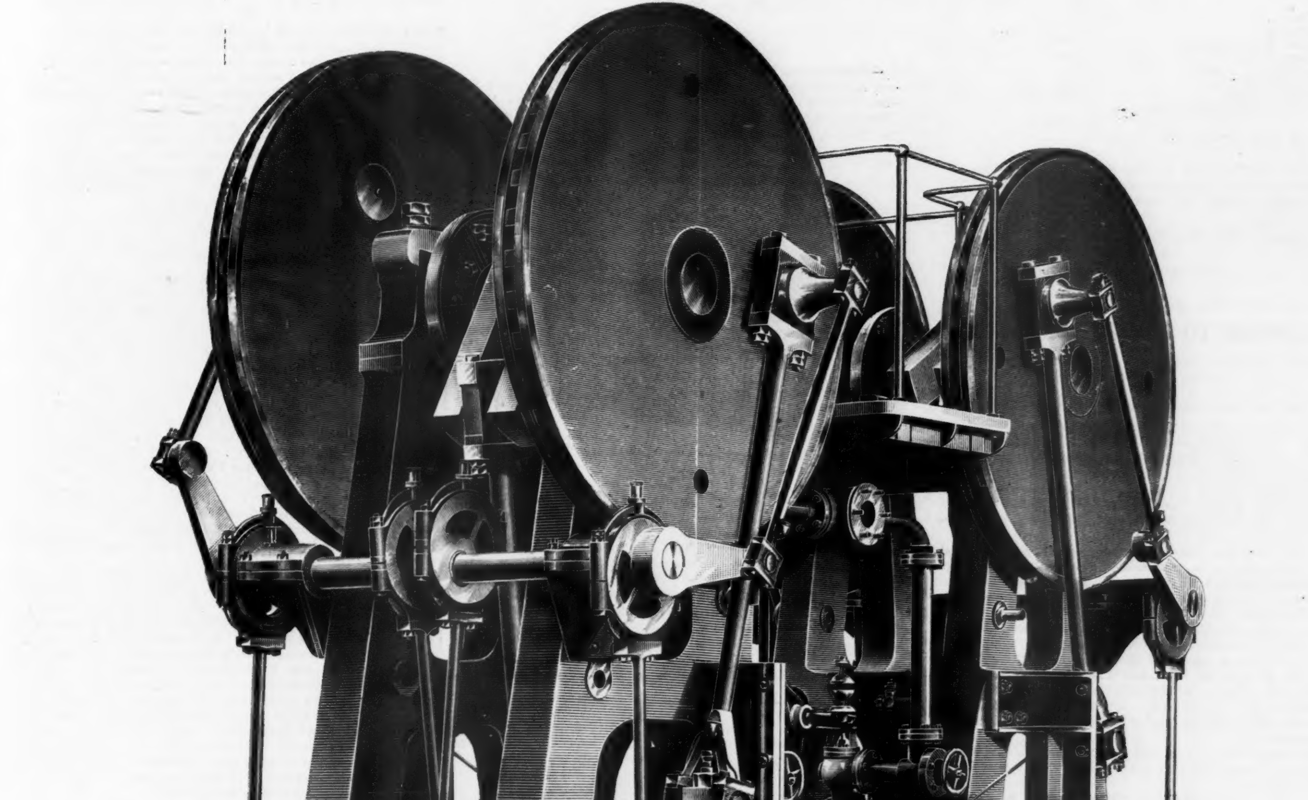
BETHLEHEM BARBETTE PLATE

We are now able to furnish a brief account and sketch of a trial of a Bethlehem plate, which took place on November 23rd and on December the 5th last. The plate is not a record breaker, nor is it double forged, but it must surely be pronounced to have behaved well. The fact is that it has not been tried at all as severely as is desirable to bring out special excellence. The plate was a Harveyed steel Bethlehem plate 12ft. × 7½ft. For a width of 4ft. the thickness was 14½in., for the last 3½ft. it tapered down to 8in., as shown in Fig. 2. The attack consisted of three rounds from a 9in. gun firing projectiles weighing 446¾ Russian pounds, or 403·3 English pounds, and three rounds from a 6in. gun firing projectiles weighing 96¾ lb. Russian, or 87·3 lb. English. The striking velocities and perforations are given in table A in next page.

It may be seen from this table that the perforating power was considerable, the maximum being 18·1in. of ordinary steel against this 14·5in. treated plate, and 14·8in. of ordinary steel against a part which was about 11in. thick. Six rounds were delivered. In every case the projectile broke up, and in only two cases was there any crack. We question if a better result than this could be

PUMPING ENGINES, COLCHESTER WATERWORKS

MESSRS. EASTON, ANDERSON, AND GOOLDEN, LONDON AND ERITH, ENGINEERS



shown with armour made in England. Yet this has been far surpassed with double forged plates.

TABLE A.

No. of. round	Calibre inches.	Weight of shot lb. English.	Striking velocity ft. sec.	Striking energy foot tons.	Perforation by Krupp's formula. Inches iron.	Perforation by Krupp's formula. In. steel ordina'y	Striking energy foot-tons per ton of plate.
1	9	403·3	1870	9777	21·7	17·3	475·6
2	9	403·3	1919	10290	22·5	18·0	500·8
3	6	87·3	2558	3961	18·3	14·6	192·7
4	6	87·3	2546	3922	18·1	14·5	190·8
5	9	403·3	1927	10390	22·7	18·1	505·3
6	6	87·3	2573	4007	18·4	14·8	194·9
							2060·1

We will now, however, give an excellent result with a single forged 15in. Bethlehem nickel Harveyed plate selected from the supply of the Indiana and Massachusetts armour, tested on February 19th, 1895, and reported by us in the issue of March 15th last, but which is well worth giving again, as we now have the photograph. The attack was made with two 10in. Carpenter projectiles weighing 500 lb. each. The striking velocity of the first was 1539 foot-seconds, and of the second 1940 foot-seconds; the striking energies being 8212 and 13,050 foot-tons, and the calculated perforations 16·2in. of iron or 12·9in. of steel, and 21·4in. of iron or 17·1in. of steel. The projectiles broke up as shown in the photograph, the estimated penetrations being 2in. and 6in. respectively. No cracking was perceptible, so it was reported, and so it appears as far as can be seen in the photograph. It will be seen then that these two results are remarkably good. In each case a severe attack has been totally defeated. We lay special stress on the last, as it is the case of a plate 15in. thick.

PUMPING ENGINES, COLCHESTER WATERWORKS.

WE illustrate above and on page 27 the pumping engines constructed by Messrs. Easton, Anderson, and Goolden, Erith Ironworks, and officially started by the Mayor of Colchester on the 7th of November, 1894.

There are two three-cylinder compound surface-condensing vertical engines placed directly over the well, each engine capable of pumping 70,000 gallons of water per hour to a total height of 247ft. The high-pressure cylinder is 14in. diameter, and the two low-pressure cylinders are each 20in. diameter, the stroke being 3ft. The crank shaft is placed over the cylinders, and has two disc fly-wheels keyed on to it.

The pumps are of the three-throw bucket-and-plunger type the rods being coupled directly to the tail rods of the steam pistons, each pump barrel being 11½in. diameter, and having a plunger 8¼in. diameter. The top box of the pumps is placed 30ft. below the engine-house floor, and is above the standing water level in the well. The barrels are placed 70ft. below the engine-house floor, and are connected to the top box by means of stand pipes supported by strong cast iron girders built into the well above the water level. Each engine is fitted with a separate air-pump 9in. diameter, 3ft. stroke, and surface condenser having 250 square feet of cooling surface. The exhaust steam passes through the tubes, and a branch off the delivery main fitted with a sluice cock regulates the amount of circulating water.

Steam is supplied by two Paxman patent economic boilers, 7ft. 6in. diameter, 12ft. 6in. long, having a working pressure of 125 lb. per square inch, and fitted with feed pumps and injectors. There is one flue in each boiler 2ft. 4in. diameter, and seventy 3in. return tubes the whole length of the boiler.

The well is 80ft. deep, 13ft. diameter at the top, lined with 14in. brickwork for a depth of 38ft.; below this it is lined with cast iron cylinders for a further depth of 30ft., and the remainder with 14in. brickwork. The standing level of the water is about 30ft. from the engine-house floor.

From an eight hours' trial recently made of the engines and boilers the following results were obtained :—

Mean speed of engines	31·5 revs. per min.
Mean boiler pressure	120 lb. per sq. in.
Mean vacuum	26in.
Total head of water	235·25ft.
Mean I.H.P.	107
Mean pump H.P.	91·04
Mechanical efficiency	85·09 per cent.
Feed-water per I.H.P. per hour	17·77 lb.
Feed-water per pump H.P.	20·09
Coal used per I.H.P.	1·75
Coal used per pump H.P.	2·05
Temperature of feed-water	75 deg. Fah.
Water evaporated per lb. of coal from and at 212 deg	12·13 lb.
Foot-pounds of work done per cwt. of coal consumed	107,692,848

The works were carried out to the designs and under the superintendence of Mr. J. Mackworth Wood on behalf of the Corporation of Colchester, Mr. Paxman being chairman of the Water Committee.

It will be noticed that the shaft carrying the excentrics is caused to rotate by two coupling rods from the main crank shaft. The arrangement is quite successful and satisfactory.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

METROPOLIS WATER SUPPLY—THE WELSH SCHEME.

SIR,—In the editorial review, in your issue of the 3rd inst., of engineering works now in progress or contemplated, you say with relation to the above scheme that "The London County Council are not yet prepared with a Bill to carry out the project devised by their chief engineer Mr. A. R. Binnie, for bringing a supply of water to London from Wales;" and as some misapprehension as to the authorship of the scheme appears to exist, we ask to be allowed to set the matter right.

The project for obtaining water for London from the rivers Usk and Wye, and delivering it by gravitation at an altitude of 300ft. above the Ordnance Datum on both the north and the south sides of the metropolis, is wholly ours, and was brought by us under the notice of the London County Council in July, 1892, as you will see by the accompanying pamphlet. The project attracted the attention of the Water Committee, and Mr. Binnie was directed to investigate it, and make a report as to its feasibility and cost, and to enable him to do this, we furnished him with detailed maps, plans, sections, and estimates of the entire works. Mr. Binnie has fully corroborated our views, and with some small variations, which in no way affect the principles of the scheme, has recommended it for adoption.

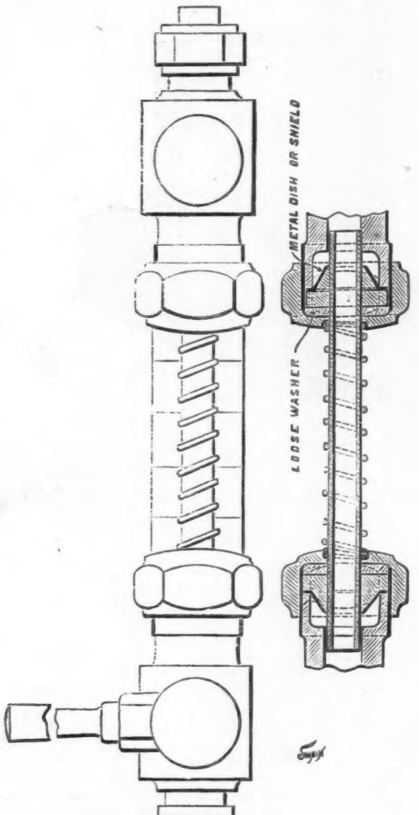
We have no reason to suppose that our position in the matter will be questioned, but we ask you to allow this communication to appear in your columns.

HASSARD AND TYRRELL, MM. Inst. C.E.

Westminster-chambers, Victoria-street, S.W.,
January 6th.

GLASS WATER GAUGE PROTECTOR.

SIR,—As at the present time the suitable protection of water gauge glasses is so much under notice, I enclose you a tracing showing a simple and inexpensive method I have designed for meeting the difficulty, and which may be of some interest to your readers. The tracing shows clearly the arrangement, which consists simply in encasing the outside of the glass with a wire spring, which is held in position by the ends resting in grooves formed in the nuts at the top and bottom of the glass. The wire spring forms a good support or backing to the glass, and when a breakage occurs it holds the pieces of glass together and prevents them being scattered about, it also keeps the glass at a more uniform temperature. As will be seen, as soon as the escaping steam and water have been shut off, the broken glass is easily removed by slightly compressing the wire spring, which may then be taken out of the recesses. We have had these guards in use on our locomotives for some time with very satisfactory results.



I have also devised an improvement in the packing by placing a conical brass shield round the conical part of the india-rubber—now almost universally used for packing glass gauges—the shield being flanged out so as to rest on the top of the glass gauge fitting; this prevents the india-rubber getting out of shape, and we find that it lasts very much longer, and has got rid of a good deal of trouble which we had in the original india-rubber rings before they were so protected.

Crewe, January 4th.

SLIDE VALVE FRICTION.

SIR,—Referring to the letter from Mr. R. Collier on the above subject, in your issue of the 13th inst., I was pleased to see the question discussed, and will, with your permission, work out a case from actual practice. Fig. 1 shows a slide valve for a locomotive cylinder 18in. diameter by 24in. stroke, the steam chest pressure being taken at 140 lb. per square inch. The slide valve is shown in its position when the piston is at the end of its stroke, that is to say, when the crank is on its dead centre, corresponding to this position of the piston. The dimensions necessary for our calculation are indicated on the sketch. Fig. 2 shows portions of the curves for normal indicator diagrams, which have been taken from actual practice, the engine being in forward gear, cutting-off at 35 per cent. of the stroke. The travel of the slide valve corresponding to this will be about $2\frac{1}{2}$in. There will be nearly a constant pressure on the back of the slide valve equal to $9\frac{1}{4}$in. × 17in. × 140 lb. = 22,015 lb. Against this we shall have in the case of the port side A of the piston a varying pressure as indicated by the curve A A_1, Fig. 2; that is to say, from the commencement of stroke of the piston to its position when exhaust begins, viz., A_1, the mean value of the curve A A_1 is about 98 lb. per square inch, which it will be near enough to assume acts upon an area equal to that of this steam port, viz., $1\frac{1}{4}$in. × 15in. = 18·75 square inches, so that the total pressure will be 18·75 square inches × 98 lb. = 1837·5 lb. The travel of the slide corresponding to this being about $1\frac{5}{8}$in.; at the point A_1, the slide valve allows communication between the steam port A and the exhaust port B, so that there will be a varying pressure represented by the curve A_1 A_2, the mean value of which is about 40 lb. per square inch, and this acts upon a constant area $5\frac{1}{4}$in. × 15in. = 78·75 square inches, plus an area varying from $1\frac{1}{4}$in. × 15in. = 18·75 square inches maximum to zero minimum; the travel of slide corresponding to the curve A_1 A_2 being about $\frac{7}{8}$in.

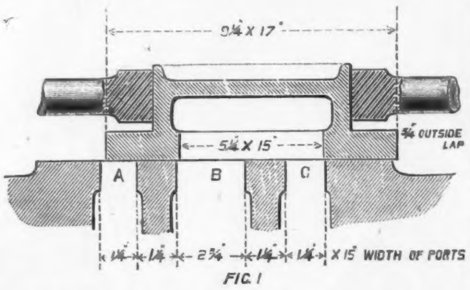

FIG. 1

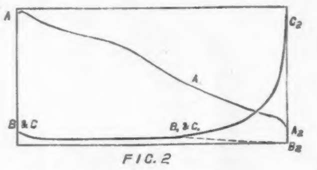

FIG. 2

But at the same time that this curve A A_1 A_2 is being traced on the port side A of the piston, another curve is being traced on the other side of the piston—viz., the port side C. So long as the slide valve allows steam to exhaust from the steam port C into the exhaust port B, that is to say, from the commencement of the stroke of the piston up to the point where compression commences, so long will there be a contrary pressure on the slide valve, as indicated by the curve B and C to B_1 and C_1, the mean value of which is about 6 lb. per square inch; this will act on an area equal to $5\frac{1}{4}$in. × 15in. = 78·75 square inches, plus an area varying from zero to $1\frac{1}{4}$in. × 15in. = 18·75 square inches maximum; the travel of the slide valve corresponding to this curve being about $1\frac{5}{8}$in. At the compression point the slide will have just closed the steam port C to the exhaust port B; after which there will be a varying pressure in the steam port C, as indicated by the compression and admission curve B_1 and C_1 to C_2, the mean value of which is about 24 lb. per square inch, and will act upon an area which it will be near enough to assume as equal to $1\frac{1}{4}$in. × 15in. = 18·75 square inches, while at the same time there will be a varying pressure on the exhaust, as already stated, due to the steam exhausting from the other steam port A into the exhaust port B. If it were not for this steam port A just coming into action when B is closed to C, the pressure line would drop in the exhaust, as indicated by the dotted line B_1 and C_1 to B_2. The travel of slide corresponding to the curve B_1 and C_1 to C_2 is about $\frac{7}{8}$in. The total work done in moving the slide valve through one complete stroke, that is to say, from any given position of the slide through its various positions and back again to the original position, will be approximately

$$\left[\left\{(22{,}015 - 1837{\cdot}5) - \left(78{\cdot}75 + \frac{18{\cdot}75}{2}\right) 6\right\} 1\tfrac{5}{8} + \left\{22{,}015 - \left(78{\cdot}75 + \frac{18{\cdot}75}{2}\right) 40 - (18{\cdot}75 \times 24)\right\} \tfrac{7}{8}\right] \frac{\mu}{12}$$

$$= (31{,}929{\cdot}21{,}875 + 15{,}785)\ \frac{\mu}{12}$$

$$= \frac{47{,}714{\cdot}21{,}875}{12}\ \mu = 3976{\cdot}2\ \mu \text{ foot-pounds.}$$

Where (μ) is the coefficient of friction between the slide valve face and its seating in the steam chest, taking this at the same value as Mr. Collier—viz., $\frac{1}{5} = 0{\cdot}2$ for dry surfaces, and $\frac{1}{8} = 0{\cdot}125$ for for surfaces moistened by the steam, we have respectively, $\frac{3976{\cdot}2}{5} = 795{\cdot}24$ foot-pounds, and $\frac{3976{\cdot}2}{8} = 497{\cdot}025$ foot-pounds.

The mean effective pressure on the piston is about 68 lb. per square inch, so that the work done on the piston during the above cycle of the slide valve will be $(18)^2 \times 0{\cdot}7854 \times 68$ lb. × 2ft. = 34,607·8656 foot-pounds, or say 34,608 foot-pounds. Let x and y represent respectively the work absorbed in moving the slide for dry and moistened surfaces, in percentage of the work done on the piston in the same time, then

$\frac{x}{100} = \frac{795{\cdot}24}{34{,}608}$ $\therefore x = \frac{79{,}524}{34{,}608} = 2{\cdot}29$ per cent. for dry surfaces,

and $\frac{y}{100} = \frac{497{\cdot}025}{34{,}608}$ $\therefore y = \frac{49702{\cdot}5}{3{,}6408} = 1{\cdot}43$ per cent. for moistened surfaces.

From this it would appear that about 2·29 per cent. of the work done on the piston is absorbed in driving the slide valve when the surfaces are dry, or about 1·43 per cent. when the surfaces are moistened. It will be observed that these figures agree very well with those obtained by Mr. Aspinall, and quoted by your correspondent—viz., 2·26 and 1·34 per cent. I have omitted to take into account the weight of the slide valve, which would probably weigh about 60 lb., or rather over half a hundredweight. If the valve was placed above the cylinder, so that the whole of this weight acted, we should have for dry surfaces $\frac{60 \times \frac{1}{5} \times 2\frac{1}{2}}{12} = 2\frac{1}{2}$ foot-pounds, and for moist surfaces $\frac{60 \times \frac{1}{8} \times 2\frac{1}{2}}{12} = 1{\cdot}56$ foot-pounds, which would require in this case to be added to the above result to be absolutely correct, but the difference is so small that it is inappreciable. If the slide is placed under the cylinders, according to the practice of the Great Eastern Railway, then to be absolutely correct in the above calculation we should take (22,015 − 60) = 21,955 lb., instead of 22,015 lb. throughout the whole calculation.

One of the chief advantages in placing the slide valves underneath the cylinders is that when the engine is running with steam shut-off, the valves will fall away from the port faces or valve seating, in which case they are not uselessly grinding away their faces and that of their seatings.

EDWARD J. M. DAVIES.

24, Harrington-square, London, N.W.,
December 23rd, 1895.

THE METRIC SYSTEM.

SIR,—Your leading article deals with this question on its general bearings, but permit me to say that you have either not read the evidence given before the Select Committee last year, or you have purposely treated it as of no account. Your presentment of the case is but a repetition of what used to be said some forty or fifty years ago, and by no means represents what has now to be considered.

Granted that the metre was originally based on a mistaken measurement, that it is really an arbitrary measure, it has now been standardised in the most accurate way, and every European country, except Denmark, Great Britain, and Russia, has adopted the metric system exclusively. All the Southern States of America, Japan, and other countries have followed suit. In the United States there is a growing disposition to adopt it; in 1890 the President transmitted to Congress a report adopted unanimously by an International American Conference, which recommended the adoption of the metric weights and measures now in use by the Governments and people of all the other American Republics, and most of the nations of Europe.

In 1893 the Consular officers of the United States were instructed to refuse to certify invoices of goods consigned to the United States unless the merchandise were invoiced in accordance with the metric system. Also in 1893 the United States superintendent of Standard Weights and Measures issued a bulletin to the effect that the international prototype metre and kilogramme had been accepted as the fundamental standards of length and mass, and that the customary units, the yard and the pound, would be treated as derived therefrom. At the present time a Government Committee of experts is considering the general adoption of the metric weights and measures. Actually countries representing a population of over 445 millions are now using the metric weights and measures, and there is good authority for saying that if Great Britain and her dependencies were to adopt them, they would be adopted throughout the civilised world.

I agree with you that some decimal fractions are inconvenient, but there is no system without some drawbacks; and when in certain cases it is quicker or better to speak of a third, a fourth, &c., it would be foolish not to do so. As the late Professor De Morgan said: "It is an abiding delusion of the opponent of decimals that he will suppose the decimalist to be under a contract never to use a common fraction." Decimals are not upheld as exclusively right, but rather as pre-eminently convenient. As to the convenience and accuracy of the metric system, the best testimony is that it is used exclusively in all scientific work.

The mere comparison of the metric units with those of our own system gives no adequate idea of the advantages of the one system over the other. For instance, in our weights and measures the units of length or bulk have little or no direct relation to those of weight, and sometimes the volume unit is a gallon, sometimes a cubic foot, and sometimes a cubic inch. There is no uniform basis on which to compare substances or results. But in the metric system it is well known that a cubic decimetre of water weighs a kilogramme; that a cubic metre of water weighs a ton, &c. We have only to multiply the volume or bulk of any substance into its specific gravity, and we know its weight. Conversely, if we know the weight of iron, brick, or other substance, we can easily find its volume by dividing the weight by the specific gravity. It is this intimate, simple, and rational relation of the several metric units and their derivatives which has had more to do with the general adoption of the metric system than any other consideration. But even you have failed to appreciate this manifest advantage, or you would not have quoted the example of the pump. Any one familiar with the metric system would know that litres, decalitres, cubic metres, or cubic centimetres of water can be immediately, and without trouble, converted into grammes or kilogrammes.

Your statement that "the history of the adoption of the metric system in France is very consistently kept in the background" is hardly fair. As a matter of fact, the very first witness before the Select Committee of 1895, Mr. Chaney, was questioned on this point. The chairman said: "In the report of the Committee on Weights and Measures—1862—there is a very elaborate account of the history of the metrical system; still I think it is very desirable to hear from you, as an authority upon the subject, a short account of the origin of the metrical system." Other witnesses were also questioned on the subject.

Undoubtedly the introduction of the metric system in France took a long time, and was attended with great difficulty. It is common knowledge; but we must remember that nearly a century ago the people generally were without education, and where there was ignorance there would naturally be prejudice. This, then, is not what should guide us in the present day; let us rather turn to any of the countries which have adopted the metric system during the last twenty years or so—for instance, Germany, Austria, and Sweden. Several witnesses stated that in neither of these countries was there any serious difficulty, and that the change was effected in a short time. In Germany an Act was passed in 1868 which made the metric system permissive from 1870 to 1872, and compulsory afterwards. Is it too much to suppose that with our present educational advantages our countrymen are less intelligent and less capable than those of other countries?

You say that in this country an Act was passed in 1864 which made the metric system optional. If you will be good enough to refer to the Act itself, you will see that it only allows contracts to be made in terms of the metric system, and that it does not authorise the use of the material weights and measures of that system. The Act passed in 1878 goes a step further, and authorises their use for purposes other than trade, and at the present day manufacturers are in this extraordinary position: Supposing a merchant in France orders a certain number of metres of cloth from a manufacturer in England, the latter cannot legally use a metre to measure it when made. He must "measure it in yards or feet, and afterwards recalculate the number of yards or number of feet which would make up the number of metres of the order"—*vide* Mr. Chaney's evidence. You urge us to take a practical view of the question, and I submit that this is not practical. In the face of the present keen competition abroad it is simply absurd.

There are many other points I could dwell on, such as the important effects on education, the urgent recommendations of British Consuls abroad, &c., but I should trespass too much on your valuable space. I must, however, correct your statement that probably "not more than a few hundred individuals manifest the smallest desire to possess" the metric system, and that the English-speaking world at large regards it "with supreme indifference." The facts are these:—

(*a*) All the Associated Chambers of Commerce of the United

Kingdom, as well as the four important chambers which are not members of the Association—Edinburgh, Glasgow, Liverpool, and Manchester—strongly advocate the adoption of the metric weights and measures, and have all passed resolutions in its favour. It was a strong deputation of these chambers which recently waited on Mr. Balfour, and he fully recognised the importance of the commercial interests they represented.

(*b*) All the leading School Boards of the United Kingdom have petitioned in favour of the proposed change, and the National Union of Teachers has unanimously passed a strong resolution in its favour. Masters of middle-class schools, including the head master of the City of London School, and other educational authorities, are also strongly in its favour.

(*c*) The Trades Councils throughout the country have taken a keen and intelligent interest in the question, and at several of their meetings it has been discussed in a practical way. At a Congress held in Glasgow, where there were 495 delegates, representing about a million and a-quarter members, and 418 different trades, a resolution in favour of the proposed change was carried unanimously, and the Parliamentary Committee was instructed to give its active support.

(*d*) The Incorporated Society of Inspectors of Weights and Measures have passed a strong resolution in its favour, and some members of this society gave valuable evidence before the Select Committee.

(*e*) Since the deputation to Mr. Balfour, the Metropolitan Grocers' and Provision Dealers' Association—essentially a gathering of retailers—discussed the question fully and critically at a general meeting, and passed a resolution in favour of the metric system being made compulsory.

(*f*) The County Council of Durham, representing a population of 750,000, and the borough and county borough of Leicester, have voted unanimously in favour of the change. Many engineers, shipbuilders, and manufacturers are also urging its adoption.

(*g*) I have already referred to what is being done in the United States. In Melbourne the Legislative Assembly adopted a motion in favour of a Universal or Imperial Union for the introduction of the metric system.

The question has grown so far, and it is growing. Within the last two months I have read hundreds of press notices and criticisms from all parts of the country, and I have been agreeably surprised to find that nearly all recognise the advantages of the metric system, and that those who hesitate to make it compulsory are influenced chiefly by the fear of inconvenience during the period of transition. In conclusion, may I express the hope that when you have had time to look over the evidence of Sir Benjamin Baker, Mr. Alex. Siemens, Captain Sankey—of Willans and Robinson—and others, given before the Select Committee, you will no longer oppose a reform which I sincerely believe we must adopt sooner or later.

J. EMERSON DOWSON.

[We have not one word to urge against the metric system. We have the strongest possible objection to Government interference. When the voice of the professional and trading people of Great Britain is unanimous, the metric system will be adopted. Until then, we accept Mr. Balfour's expression of opinion as correct and statesmanlike.—ED. E.]

EARLY LOCOMOTIVES.

SIR.—It is interesting to read the letter of Mr. John Wilson, page 11, and to have the views of one who has had such a long railway experience, I therefore trust he will throw more light upon the subject. Mr. Wilson gives a diagram to illustrate a design by Mr. Grantham; no doubt a large number of engines were designed, but Mr. Wilson does not say that the engine was ever made. In the writing of locomotive history I am always careful to refer to engines actually built. The books of Messrs. Mather, Dixon, and Co. show very clearly the engines built by the firm, but they do not give any details whatever of engines with wheels larger than 8ft. Mr. Wilson does not give any date, or maker's number, or for which line the design was intended. Messrs. Mather, Dixon's drawing of the Ajax, and also of the 8ft. wheel, are reproduced in your issue of October 25th, 1895, and also in the fourth edition of my book, "Locomotive Development," page 220, and probably Mr. Wilson can remember that engine when under construction. Undoubtedly there was one engine upon the Great Western Railway having a driving wheel of 10ft. diameter, but, at different times it had three names, Hurricane, Grasshopper, and Ajax, and this fact is the root of the whole question. Robert Stephenson did not say that there was more than one 10ft. wheel engine. Giving evidence before the Gauge Commission, August 6th, 1845, question 107, he stated "there was one of 10ft., I know." This answer proves that Stephenson did not know of more than one.

In these days, when we consider 85 miles an hour a high speed, and laugh at those who claim a speed of 100 miles an hour in America, it is rather astonishing to hear from Mr. Wilson that the Cornwall of 1847 went 120 miles an hour; but surely your readers will expect Mr. Wilson to furnish details as to length of run and the way in which the speed was timed. We are told by Mr. Wilson that it was on the trial trip down Madeley Bank.

The late Mr. Alexander Allan was the superintendent of the Crewe Works at the time when the Cornwall was built, and he was on the foot-plate when the trial trip was made; and a few years ago he lent me all the drawings of the engine and details of her working. I have now before me a letter written by Mr. Allan, in which he informed me that the highest speed attained by the Cornwall was on her trial trip when running down Madeley Bank; it was "79" miles an hour. That is my authority for the statement made in my book, page 99. Mr. Allan, who was in charge of the experiments, gives 79 miles an hour—surely a very different statement to 120 miles an hour. Probably Mr. Wilson will explain the important difference of 41 miles an hour.

Mr. Wilson is indeed quite in error when he supposes that I shall "not thank him for corrections." On the other hand, my object is to make my book as correct as possible; but in view of the letter I have from the late Mr. Allan, I certainly cannot accept the "correction" of speed in this case, as I do not believe that any locomotive engine in the world has ever run at 120 miles an hour.

When Mr. Wilson states that the Grasshopper had 10ft. wheels I quite agree with him, as it was but the second name of the Hurricane; but when he refers to it as "the 100 miles an hour engine," I must ask for some proof that such a speed was ever run. It is easy to write 100 miles an hour on paper, but it requires a great deal of attaining; in fact, it never has been attained by engines on rails. If Mr. Wilson thinks otherwise he should produce proofs.

CLEMENT E. STRETTON.

Saxe-Coburg House, Leicester,
January 6th.

SIR,—Somewhat late in the day there is at length laid before us by Mr. John Wilson in your issue of 3rd inst. a diagram which purports to be that of a 10ft. driving wheel locomotive—see page 10. This diagram may represent a design, but if so, that is all.

I fail to see Mr. Wilson's object in now producing this drawing, unless he is anxious to re-open this discussion, which, after having lasted for many weeks, has for a short time been lying dormant. Why did not Mr. Wilson produce his drawing before this? Mr. Wilson does not appear himself to be very certain about his diagram. In one paragraph he speaks of the engine as if it had really been built, and as if he had actually been present at its erection. In the very next paragraph he seems to throw doubt on the existence of such an engine altogether. What does he mean? Why does he not tell us whence the drawing came? What was the name of the engine, if it ever was made, and the maker's number? He gives no information by which his engine can be traced, neither does he say for what company it was built, nor does he give any details of any sort.

As to Mr. Wilson's reference to the allegation that there were two or more locomotives on the Great Western Railway with 10ft. driving wheels, I may say that, so far as I can ascertain, Mr. Stephenson did not say there were more than one. Mr. Wilson also mentions Mr. Dean's name, but as has already been shown, Mr. Acworth stated on Mr. Dean's authority that the Hurricane was the only 10ft. wheel engine on the Great Western line. Certainly there is no trace of any other in the records and books of the Great Western Railway. Mr. Wilson mentions an engine named Grasshopper? Is he, after all that has been written on the subject, still in ignorance of the fact that Grasshopper and Hurricane as well as Ajax were all one and the same engine?

Will Mr. Wilson favour us with details of the 100 miles and 120 miles an hour speeds he mentioned; and will he inform us who timed the running, and how it was done? This information would be interesting, and might be useful to our friends across the water who have not yet, so far as I know, reached a speed of 120 miles an hour.

D. H. LITTLEJOHN.

Dundee, January 5th.

SIR,—Those of your readers who are interested in this discussion will have derive much pleasure from the drawing supplied by Mr. J. Wilson, together with the explanatory letter, appearing on page 10 of your issue for January 3rd.

It will be observed that Mr. Wilson's letter and drawing not only prove the undoubted existence of the 10ft. wheel locomotives constructed by Mather, Dixon, and Co., but they are also proof positive on another point, viz., that some of the original broad-gauge engines were fitted with a prow in front.

In the "History of the G.W.R.," page 69, I stated, "Some of these early engines were provided with a projector in front, extending from the smoke-box to the buffer beam, and shaped like the bow of a ship." Up to now, although Mr. Stretton and his two friends have given your readers what they describe as full details of all the original broad-gauge engines, no mention appears to have been made by these three gentlemen of this prow-shaped projection. But the very fact that they did not deny that some engines were so fitted must have convinced students of locomotive history that other engines than those stated by Messrs. Stretton, Littlejohn, and Greenly must have existed, despite the extremely vehement repudiation of these three gentlemen.

Mr. Stretton is in another very awkward predicament, for, according to Mr. Wilson, I understand that he has stated that he has a blue print of a disc wheel made at Bath-street Foundry in 1838. Mr. Wilson, who certainly ought to know, says there was no Bath-street Foundry in 1838.

G. A. SEKON.

SIR,—With reference to Mr. J. Wilson's letter, I may state that I know for a fact that no such engine was ever run on the Great Western Railway. If such an engine, as Mr. Wilson illustrated it, was designed, was it built and did it work? In regard to the statement that the Cornwall ran 120 miles per hour, we laugh at the Americans and their records (?) of 112 miles per hour. The official record of the Cornwall was about 79 miles per hour. Mr. Wilson's letter does not prove that there was more than one 10ft. driving-wheeled engine on the Great Western rails. I would not like to say that there was not a 10ft. locomotive driving-wheel ever made, but I say emphatically that the Ajax on the Great Western Railway had a spokeless wheel which was only 8ft. in diameter.

London, W., January 6th. HENRY GREENLY.

SIR,—I find two slight errors in the printing of my paper on "Early Locomotives." The Grasshopper with sandwich frames was the *lost*, not the *last*, 10ft. wheel locomotive. The other should read, Mather, Dixon, and Co. *delivering*, not *relining*, engines.

JOHN WILSON.

165, Onslow-drive, Dennistoun, Glasgow, January 6th, 1896.

NAVAL ENGINEERS.

SIR,—Your outspoken protests against the present position leads me to wonder why the state of affairs revealed by the Lightning court-martial has not been commented on. Apparently during the trials there were one commissioned executive officer, two commissioned engineer officers, and two junior non-commissioned officers, and on failure of the commander, the command devolved on a non-commissioned officer.

The engineers are highly educated men, far above the average of naval officers; one has passed a special course at the Royal Naval College, both are in the prime of life—probably about thirty-six—have had years of sea service, and yet are required to serve under the orders of a man who is comparatively uneducated, and in any other relation of life would be so far beneath the chief engineer as to be only known as master and servant.

What would be thought of a railway management which could contemplate any emergency in which the locomotive engineer of the line, was required to take orders from, and ask the permission of a guard, before he could do anything? Yet such is the position of a naval engineer.

Your articles even scarcely show the importance of a naval engineer. The modern warship without the engineer is powerless; he alone knows how to propel and steer the ship, manage the guns and torpedoes, maintain the water-tight doors, and yet must do all this under the orders of an ordinary blue-jacket. Whilst responsible for more than one-third of the crew, he has not so much authority as the youngest sub-lieutenant. In most places it is recognised that authority and responsibility go together, but not so in the Navy, at least so it appears to a CIVILIAN.

January 4th.

PERMANENT WAY.

SIR,—Mr. Tratman discusses a very interesting question, the relative merits of the bullhead and flange rail, and he makes out a very good case for the latter. He will not convert English engineers, however. To use an Americanism, "We have been there." We have done all we could to make the flange or Vignoles rail a success, and failed. I take it that the word "success" can be defined in terms of money, and in that only. Now the flange rail system is in the long run more costly than the bullhead and chair system, and so has been rejected. It would be waste of time and space to tell the whole story over again. The broad facts can be very briefly stated:—Given a certain weight of steel, say, 85lb., to be made into a yard of rail, it is clear that if we put a large proportion of this in a bottom flange we shall have less left for the top. If we keep the top standard size, we must take it out of the web. The result is, of course, that the flange rail not being so deep as the bullhead, lacks vertical stiffness. To compensate for this the sleepers must be put closer together, and the ballast of the best. In America timber is much cheaper than in this country, and as Mr. Tratman tells us, the best flange railroads are apparently wooden decks on which the rails are laid, the ballast being of the best possible type. To get stiffness, the feebleness of the rail is helped by the excellence of the road bed. We have tried all this over here, and we find that in the long run we get a stiffer, and much cheaper, and more durable track with chairs and cross sleepers than can be had in any other way.

In the course of my life I have seen almost every system of permanent way tried that promised anything—from the Barlow rail on. The existing chair and bullhead is a survival of the fittest, and its adoption in the United States is only a question of time. I fancy Mr. Tratman knows very well what are the defects of both systems, but, lest he should have forgotten one, I may point out that in facility of repair, renewal, or packing up, the American system cannot compare with the English. I could remove and replace ten bullhead rails while Mr. Tratman was doing the same with one flanged rail; spiking cannot compare in efficiency with the securing of chairs with hollow treenails and driven bolts. If you unspike a flange rail you ruin the sleeper, and as to the screw spike system, it only manages to get along in the most watchful hands.

I quite agree with Mr. Tratman that the daily press of the United States makes too much of track defects, but, on the other hand, Mr. Tratman must know that it is one thing to pick out a few thousand miles of really first-class line and quite another to deal with 50,000 miles or so, much of it the worst track in the world.

The probability is that if we take an 85 lb. rail on the best portion of the Pennsylvania road, and a bullhead 85 lb. on, say, the Great Northern, it will be found that one road is as good as the other to run over. This being granted—and I do not think Mr. Tratman will dispute it—the only point remaining for consideration is relative cost. Will Mr. Tratman go into this question and let your readers know what the first cost and cost of maintenance per mill is on a first-class American line? I have no doubt he will, if he can, but I much doubt his power; at all events, I tried very hard a few years ago to get the requisite data, and failed; I was told, indeed, that from one cause and another it was not available. It is, of course, well known in certain circles that American railway finance is chaotic in the matter of detail. It is possible, however, that Mr. Tratman may be now able to supply the missing figures. If he can and will, he will give information not hitherto available in this country, or indeed, in the United States. The figures should give the total maintenance cost of, say, 100 miles of first-rate track for five years at least.

December 27th, 1895. SEXTUS.

ELECTRIC LIGHT ENGINES.

SIR,—As you have done me the honour to make a few editoria comments on my letter that appeared in your issue of January 3rd, I should feel obliged if you would allow me to reply to them. On reference to my letter it will be seen that I nowhere charge you with casting a slur on "engine builders." What I said was that a slur was put upon "our stationary engine builders." What I endeavoured to repudiate was the very unjust comparison that was made by you on page 608 of your issue of December 20th, 1895. You there say, "The necessities of electric lighting almost compel the adoption of a marine type of engine as the motor, and it is obvious that if we require a marine engine we should not place the order with a stationary engine builder, more especially as our marine engineering has no rival in the world, while many stationary engine builders must unfortunately be classed below some of the continental builders—the Sulzers, Vandenkerchoves," &c. &c.—to wit, in point of reputation.

I think most impartial critics will agree with me in thinking that though the excellence of our marine engineering is indubitable, the comparison is so made as to discredit to an unnecessary extent the merits of the stationary engine builder. In your appended criticism you ask, "Where is the British marine engine builder that can be classed below the foreign marine engine builder?" If by this you mean that any British marine engine builder, however bad, is better than any foreign builder however good, I fear that your question savours rather of blind patriotism than clear criticism. Waving these controversial points, which will be differently answered according to the individual bias of the critics, it is surely too much to say, in the teeth of such strong evidence to the contrary, that the necessities of electric lighting "almost compel the adoption of engines of the marine type." In the first place, such engines are only suitable in the case—admittedly one of large and growing importance—of direct-driven machines.

Now in America, where there are perhaps more electric installations than the whole of the countries of Europe together, the engines of the marine type might be counted on one's fingers; in our own country they are, to say the least of it, extremely rare. The only safe generalisation on this question is that in all probability the high speed engine will outlive and supplant the slow speed motors which are now receiving diminishing favour. "Of all forms of error prophesy is the most gratuitous," and yet in spite of this sage warning, it is without incurring very great danger that one ventures to predict that the stationary engine builder will continue to do the lion's share in the matter of manufacture of electric light engines in the future as he has done in the past.

6, Cyprus-street, Bolton. ROBERT A. BRUCE.
January 8th.

DROWNED PUMPS.

SIR,—It may be in the recollection of your readers that a few weeks ago the Dungannon collieries, Ireland, were suddenly inundated by an enormous body of water tapped from some old workings, and which unfortunately resulted in serious loss of life besides overwhelming the pumping machinery.

Mr. Donald Munro, the managing engineer of the colliery, advises us that they have been able to start the large Cornish duplex steam pumping engine, supplied by us to the colliery, and that it is working 60ft. under water. We think this will be of interest to those who have to do with underground pumping machinery, and shows in a remarkable manner the capabilities of the direct-acting type of engine.

JOSEPH EVANS AND SONS.

Wolverhämpton, January 8th.

METALLURGICAL LABORATORY, KING'S COLLEGE.—We are requested to state that there are one or two free admissions to the evening classes in this department now available.

THE SLOOP PHŒNIX.—The Phœnix, sloop, at Devonport, has been moved into the Sound to have her compasses adjusted, in readiness for a six hours' preliminary trial of her machinery in the Channel. The vessel has not yet been outside the Hamoaze, as on being launched from Devonport Dockyard she was at once transferred to Keyham. Considerable interest will be taken in her steam trials, in consequence of her engines and boilers having been manufactured by and fitted in place by the Keyham Factory. She was laid down on the 26th July, 1894, and would have been completed in June last had it not been for the pressure of other machinery work not anticipated when Keyham's programme of work for the current year was mapped out. When ready for sea the total cost of the vessel will have been just over £66,000.—*Western Morning News.*

WAGES IN ENGLISH AND CONTINENTAL IRON TRADES.—We are still without the report for which the iron trade has been so anxiously looking of the joint deputation of ironmasters and ironworkers, which considerably more than six months ago, at the inspiration of Mr. Jacks, the President of the Bristol Iron Trade Association, journeyed to the Continent to investigate the question of ironworkers' wages and hours, and other competitive conditions in continental iron and steel manufacture. The deputation, though carrying with it the authority of the British Iron Trade Association, was by no means confined to that body, but included representatives of the North of England, and Scotch and Midland Iron Trade Wages Boards, the Northern Iron and Steel Manufacturers' Association, and the Cleveland, and Cumberland, and Lancashire Blast Furnacemen's Association. The delegation was, therefore, in a way representative. A singular dispute has, however, now arisen between the operatives' and employers' sections, and this is at the bottom of the long delay in the publication of the report, and comment in iron and steel circles is following. A divergence of opinion has developed at the last moment regarding the character of the report, and the matter is not an easy one to settle. The men's representatives, it is understood, declare that the masters want to prejudge the results obtained, while the employers, on the other hand, state that if they were to consent to the workmen's views only a partial and one-sided report would be presented to the trade, and the iron industry as a whole would really be without the very information which the deputation mainly left our shores to collect. How the situation will end is doubtful. There may be two reports—one by each section—or there may be a minority and a majority report.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

Student.—*It is the Technological Dictionary of the Physical, Mechanical, and Chemical Sciences—English-German and German-English. London: Symons and Co.*

Stocktonian.—*The last edition of Molesworth's Pocket-book gives the formulæ you require, but some knowledge of the subject is necessary as well as formulæ. Adams's little book on "Lattice Girders and Roofs"—Spon—may help you, but you had better consult also such works as Stoney's "Stresses on Girders and Roofs," and Claxton Fidler's "Bridge Construction."*

SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. £0 14s. 6d.
Yearly (including two double numbers) .. .. £1 9s. 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. The Engineer *is registered for transmission abroad.*

A complete set of The Engineer *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
Half-yearly .. .. £0 18s. 0d.
Yearly .. .. £1 16s. 0d.

Thick Paper Copies—
Half-yearly .. .. £1 0s. 3d.
Yearly .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of The Engineer.

MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, January 14th, at 8 p.m. Paper: "The Sanitary Works of Buenos Ayres: Sewerage, Drainage, and Water Supply," by the Hon. R. C. Parsons, M.A., M. Inst. C.E. Friday, January 17th, at 8 p.m. Students' meeting. Paper: "Iron Tunnels," by Mr. W. O. Leitch, jun., Stud. Inst. C.E. Mr. J. Wolfe Barry, C.B., F.R.S., vice-president, in the chair.

The Institution of Electrical Engineers.—Thursday, January 16th, at 8 p.m. Presentation of premiums. Inaugural address of the President, Dr. John Hopkinson, M.A., F.R.S.

Society of Arts.—Tuesday, January 14th, at 8 p.m. Applied Art Section. Paper: "The Poster and Its Artistic Possibilities," by Gleeson White. Ernest Hart, D.C.L., will preside. Wednesday, January 15th, at 8 p.m. Paper: "The Making of a Great University for London," by Professor Silvanus P. Thompson, D.Sc., F.R.S. Lord Reay, G.C.S.I., G.C.I.E., will preside. Thursday, January 16th, at 4.30 p.m. Indian Section. Paper: "The Shan Hills—Their Peoples and Products," by Colonel R. G. Woodthorpe, C.B., R.E., Indian Survey Department. The Right Hon. George N. Curzon, M.P., will preside.

Royal Meteorological Society.—Wednesday, January 15th, at 7.45 p.m. Address: "Meteorological Observatories," by the President, Mr. R. Inwards, F.R.A.S.

THE ENGINEER.

JANUARY 10, 1896.

THE ARMOUR OF PEACE.

Si vis pacem, para bellum. Amidst the surrounding gloom, the United States threatening us, South African affairs most deeply involved, and the Emperor of Germany adding to the difficulty of the situation by his unguarded expressions of sympathy for the Boers, one characteristic of our position as a people shines prominently forth—we are alone in it. To many the knowledge of this fact would appear to involve a sense of uneasiness or insecurity. We would venture to combat the accuracy of this opinion. That we find ourselves alone in our position amongst the nations of the world, during such critical junctures as the last few weeks have afforded, is not to be wondered at. It is the natural corollary to the theorem of our position as standing alone amongst the nations in regard to instincts, tastes, and ambitions. It is the penalty of the greatness of our views in regard to empire.

We have always stood alone in this connection. The factors of imperial greatness, upon which the British empire rests and ever has rested, are exhibited in the Legend beneath the Royal Arms, "Dieu et mon Droit." Our confidence in the integrity of this national principle, which has actuated all the true political feeling of our country, and prompted every war in which we have been engaged, has never been shaken. When a crushed and writhing Europe appealed to Great Britain for relief from the military despotism of the Corsican Adventurer, what did this nation do? A fleet, such as the world had never before seen, was prepared, with such men as Nelson and Collingwood in command; the great Duke of Wellington was despatched with an army; and, without a dream as to increase of territory, or a thought as to self-aggrandisement, all the vast resources of the empire were employed, and all its mighty sinews were strained, to destroy Napoleon. This desired end was accomplished; arms were laid down, and battleships returned to their quiet berths at Hamoaze and Spithead. Where, amongst the other nations of the world can we find one that has been thus true to its principles of unselfishness and integrity after a successful campaign?

Strong in the confidence which such a legend as ours—"God and my Right"—can afford, we would reason temperately with those who, on the other side of the Atlantic, are seemingly careless as to the prospect of war; a war which, so far as one can judge, must, in the existing unpreparedness of the United States navy, terminate in disastrous consequences to her, and in the transfer of such of her warships as might be afloat after the expiration of hostilities, to the flag of Great Britain. It is, however, to the rational and peace-loving element of the States that we would confidently appeal. There is everything to lose and nothing whatever to be gained in a fratracidal war between the two great English-speaking races of the world. We are essential to one another, and war would dislocate all the racial, commercial, industrial, and social ties by which we are connected. Such a thing must never be.

But our national "Legend" involves a great deal. The factors of empire are not altogether of a sentimental character. Although designed with a view of upholding the grand principle of integrity which runs through them all, they are nevertheless associated with matters essentially material. This article is headed with the expression "Armour of Peace." Now, whether the curious spectacle of a whole Europe practically in arms should be regarded as a refutation of the old aphorism, *si vis pacem, para bellum*, or as an argument in its favour, is certainly a matter of opinion. But there can be no resonable doubt that, for an empire constituted as is ours, the expression "Armour of Peace" has but one signification. As applied to our Navy it is singularly appropriate. Welding together, as our Navy does, the many links in those chains which compose the imperial lines of communication all over the world, it occupies a position altogether non-aggressive. It is practically without a compeer, and has no occasion to threaten any one. It is thus unique as a protective element.

And here we are brought face to face with the most important feature of our subject. We have stated that our Navy should be regarded essentially as "Our armour of Peace." But in order to preserve its attributes of characteristic peacefulness, it must be relatively strong; and when we look around us in the increasing gloom which overshadows the early days of 1896, the necessity becomes more clearly imperative for an extensive overhaul of this, our armour of peace. We have not a word of complaint against either of the three administrations, which, without considering party politics, have, for the past nine years, laboured so successfully in the development of a magnificent fleet of battleships, cruisers, torpedo boat destroyers, and torpedo boats. We believe that the monies voted have been most judiciously expended. But ships, more ships, and still more officers, blue-jackets, and stokers are wanted. 40,000 more men should be added to the Navy forthwith, and the number of cruisers should be augmented by at least fifty. So far as regards battleships, we have already a considerable preponderance over those of any two foreign naval Powers; but in cruisers we are sadly defective. We want at least a dozen of the Buenos Ayres class, possessing 23 knots speed, which should be commenced forthwith. The country is ready, able, and willing,—nay, longing—to supply £50,000,000 if required. It should be voted forthwith. *Si vis pacem, para bellum.*

THE ROYAL ORDNANCE FACTORIES.

The *Times* has admitted into its columns correspondence relating to the constitution of the Royal Factories, to the quality and cost of the warlike stores manufactured in them, and to the nature of their accounts. The letters consist entirely of vague and unsupported charges, intended to serve as a base to the proposition that it is absurd to expect efficient and economic management of factories devoted to the production of military or naval stores, where such factories are not under military rule; and that the present organisation in some way has severed the connection which should exist between the military side of the War-office and the manufacturing departments. We should not have cared to devote space to the refutation of these absurd propositions, were it not for the mischief which such unsound statements are apt to produce when uttered in the columns of the leading journal. We imagine that it hardly requires any argument to show that the user of a watch need not necessarily be competent to direct the manufacture of watches, nor that people who are capable of enjoying a good dinner must, for that reason, be the most competent to cook it. We would rather address ourselves to an examination of the theory on which the present system of the supply of warlike stores is based; a theory which seems to be very generally overlooked, and especially by the military element, which the improved organisation has deprived of much power and patronage.

The production of warlike stores demands knowledge and experience more extensive than is to be found in any one individual, and the changes taking place are so rapid that any one officer confined to the duties of manufacture would soon get out of date and out of touch with the services to which he is supposed to belong. To meet these circumstances the production of military and naval stores has been divided into three stages. The first stage embraces the inception and design of new stores, the examination of new inventions and proposals, and the decision of doubtful points arising during manufacture or inspection. The duties connected with this stage are carried out by the Ordnance Committee, a body composed mainly of military and naval officers of distinction and on the active list, who serve on the Committee for a few years, and are constantly being replaced by men fresh from the fleets or from the active army, and who on that account are presumed to be cognisant of the current and ever-changing wants of the two services. They are aided in their deliberations by two civil engineers of the highest standing, by the chemists to the War Department and the Home-office, by the Director-General of the Ordnance Factories and his staff, by special military experts in the several arms of the services, and, in addition, not unfrequently by private manufacturers called in with reference to very special subjects. The practical work of the Committee is carried out at the butts at Woolwich Arsenal, at Shoeburyness, at Lydd, at Oakhampton, at Hythe, by the Excellent, and in the Royal Factories which are open to the Committee at all times for illustration of mechanisms, for processes of manufacture, and for carrying out experiments connected with the production of new stores.

The second stage embraces the mere manufacture of stores according to the sealed patterns and specifications recommended by the Ordnance Committee and approved by the Inspector-General of Ordnance, or by the Director of Naval Ordnance. It is this portion of the work, so much of it, at least, as is not confided to private manufacturers, which the late Mr. Stanhope decided to place in the hands of a civilian chief, and, in our judgment, the decision was eminently sound, and the principle should be further extended, as indeed was originally recommended by Lord Morley's Committee, till the military and naval elements in the executive are abolished altogether. It surely is as irrational to place a soldier or a sailor, who has had no technical training, and knows nothing about the management of workmen, suddenly in charge of a very large factory carrying on a varied and complicated manufacture, as it would be grotesquely improper to confide the command of a regiment or of a ship to a civilian. In both cases the person appointed may become efficient in course of time, but at the outset he would be merely an automaton, moved by the inferior, permanent, and technical staff, and their influence would be very difficult to shake off, especially under the old system when the appointments were made only for a few years. The Government should unquestionably select for superintendents and other subordinate officers, men who have had a thorough training in the management of large private works, who themselves know how best to conduct manufacture in all its details, and are judges of the amount of work men may be fairly expected to turn out. Throughout the *Times* correspondence we have alluded to, we have not observed that any question has been raised as to the competence of private manufacturers to turn out guns, carriages, ammunition, and other warlike stores; yet, with one notable exception, these firms are not under military direction, notwithstanding which no one can question the excellence of their products, and if this be so, why should not the Ordnance Factories achieve like results under entirely civil management?

The third stage of supply includes the most important and valuable Inspection Department. The essence of this is that it is entirely independent of the manufacturer, whether in the Government factories, or in private trade, but is directly dependent on the Inspector-General of Ordnance and the Director of Naval Ordnance, who are primarily responsible for the stores supplied from whatever source. In order to preserve this essential independence it is necessary that the two officers above named should be in no wise responsible for manufacture. They are responsible for designs and specifications; they are responsible for the stores accepted being in accordance with those designs and specifications; and their judgment should therefore not be fettered by the desire of screening the shortcomings of factories, for the economical conduct of which they might be also responsible. The Inspector-General of Ordnance selects his inspecting staff from officers of the army, generally the artillery, and makes the appointments for a short term of years. The actual viewing, gauging, &c., is done by civilian subordinates. The Navy follows a much wiser course, and makes its inspecting officers naval engineers, technical men, who have been trained to the work, and whose appointments are therefore practically permanent, because if an officer be changed his successor does not come raw to his duties but is familiar with them from the outset.

It is alleged by the writers whose statements we are traversing that the work turned out by the Royal Factories is bad and dear. With respect to the first charge it is evident, from what we have stated, that if the work be bad, the military and naval inspection departments cannot be doing their duty; but technical men are well aware that the charge cannot be maintained for a moment, it is too well known that the work of the Royal Factories is uniformly excellent, and it is a libel on the Inspection Departments to assert the contrary, for nothing can exceed the vigilance and impartiality displayed by them in accepting stores for the service. With respect to the cost of the work, the charges are as sweeping as they are vague and indefinite. The production accounts of the Royal Factories, published annually, tell us indeed the exact cost for the particular year of each store manufactured, but no such account is published of the cost of similar stores supplied by the trade; indeed, the tenders are kept confidential, so that the public has no means of judging, except in a few instances when, in the case of a few important manufactures, the prices gradually leak out, and in such cases the Royal Factories may be shown to work to advantage. Cordite, gunpowder, rifles, small arm ammunition, quick-firing ammunition, heavy guns, and such like, are produced more cheaply in them than by the trade; notwithstanding which we believe that if the factories were entirely under trained civilian management the cost is still capable of considerable reduction, and we have little doubt that when, in course of time, General Maitland's well laid plans are thoroughly carried out, considerable further economy will be realised.

There remains one other matter to touch upon, and that is the alleged involved and chaotic state of the accounts. A considerable familiarity with such matters leads us to the conclusion that the chaotic state is not in the accounts. The Accountant-General and the Director-General of Ordnance Factories have to appear annually, and publicly, before the Parliamentary Committee on Public Accounts, to answer for their stewardship of the national funds expended in the factories during the past year. The Committee is assisted by representatives from the Exchequer and Audit Department, and from the Treasury—experts, it must be remembered, in accounts; and yet, although the transactions dealt with cover an expenditure of some 2¼ millions of money, in many thousand distinct orders, the two responsible officers are able to satisfy all inquiries in a couple of hours of a single afternoon; and the greater part even of that time is taken up in explaining small slips and discrepancies, which the diligence and acuteness of Sir Charles Ryan's staff has been able, through the year, to detect. This does not look like a state of chaos, or of special difficulty in understanding accounts; although the evidence before the Committee does also show that efforts are being made to bring to a state of uniformity and accuracy as to cost keeping, accounts which years of military misrule had well nigh brought to a state of confusion.

The Royal Factories, it must be recognised, are weighted by considerations which do not affect private firms. With respect to the management of the personnel, vested interests have to be considered, together with the interferences of members of Parliament, on behalf of men possessed with votes. With respect to materials and productions generally, those that turn out defective in the slightest degree cannot be got rid of to advantage, as is possible from the factories of private firms. The Royal Factories are probably better conducted than most private establishments, they can no more claim perfection than any other human enterprises, and they certainly do not deserve the indiscriminate, we were almost going to say vindictive, charges which have been brought against them, and it is perfectly plain that the military element has a large preponderance in determining the nature as well as the quality of the national warlike stores; and can scarcely complain of being out of touch with the manufacturing departments.

THE THAMES AS A HIGHWAY.

THE London County Council have appointed a Committee who, with the assistance of the engineer, are to report on the possibility and means of restoring to the Thames its former importance as a highway. If by this is intended the revival of the steamboat passenger traffic on a commercial basis, we fear that the attempt will prove a failure. The decadence of this traffic commenced thirty years ago, and the circumstances which caused it are, despite of struggles by those concerned to overcome or ignore them, stronger to-day than ever. The old wherries, safe and well-managed as they were, and also the earlier steamboats, lost much of their monopoly when the Greenwich and Blackwall Railways were opened, and omnibuses introduced from the City to Westminster. But London Bridge Station and the old Minories terminus of the Blackwall line were difficult of access, and the high omnibus fares in those days from the Bank to Charing Cross and Chelsea left ample scope for the steamboats. So that there was not only a regular service of cheap boats between Chelsea and London Bridge, and thence to Woolwich, but there were hourly boats to Erith, Greenhithe, and Gravesend. This last service, except for holiday and pleasure traffic, was practically destroyed by the opening of the Tilbury line on the north bank and the extension of the North Kent and Greenwich lines to Cannon-street and Charing Cross. But there was still room for steamboats between Chelsea and Woolwich, for the omnibuses along the Strand were dear and uncomfortable, and the riverside districts below London Bridge were as yet inaccessible, especially such places as the Commercial Docks and Millwall. The opening of the District Railway was the heaviest blow to the system of up-river boats; and when the railway was extended *viâ* the East London line and Thames Tunnel to New Cross, the great convenience was obtained by Shadwell, Wapping, and Rotherhithe of half-hourly trains to Westminster. Finally, the branch from the Poplar Station of the Blackwall line to Millwall and North Greenwich opened communication with the remote and long neglected Isle of Dogs.

From the causes here enumerated, it appears hopeless to establish a remunerative service of steamboats to ply at all seasons of the year. This is much to be regretted for several reasons. It is certainly pleasanter on a bright day to take the river from the City, than to breathe the vitiated atmosphere of the underground railway. But it is not always bright weather, and moreover, by the time a passenger from the Bank, following the windings of Thames-street, has reached the deck of his steamer, he might have been able by railway to arrive at Westminster Bridge. The landing places *en route* are not so contiguous to the main streets, as, for instance, are those of the Seine boats in Paris, and in the latter city there is little opposition. Undoubtedly on the Thames the steamboats afford a convenient means of cross river communication. If the Archbishop of Canterbury desire to consult his ecclesiastical lawyer in the Temple, he can embark with advantage at Lambeth Palace; and if, armed with the advice so acquired, he has business at St. Saviour's, Southwark, with the Bishop of that diocese, he can reach the Surrey side of London Bridge from the Temple stairs more quickly than by any other means. But such combinations and conveniences will hardly support a line of steamers. It is not only the railways that have taken away the river traffic, but the cheap modern omnibuses. The low fares between the City and Westminster, while due partly to improved vehicles, are rendered possible only by the easy traction on the asphalte paving and by the low price of fodder. On this latter advantage depend almost entirely the dividends of the omnibus companies. The fact that without the steamboats Londoners would have few opportunities of seeing their river, is another reason why we wish to retain them. The larger part of our provincial and foreign visitors limit their easterly explorations to the Tower of London, and do not see that real greatness of our city, which only a voyage through the port of London can show them. It has been too much the fashion to sneer at the Thames steamboats as of a past and imperfect age. Their chief defects were the want of deck shelter, and the stuffy cabins, which rendered them uncomfortable on a cold or rainy day; but under the modern management of the Victoria Steamboat Association great improvements have been made in these respects. In regard to speed the old boats were as quick as could be permitted on a crowded river, and the oscillating engines — almost all made by Penn—were models of symmetry and lightness; and the boats were smartly handled.

It is possible that we have misjudged the purport of the County Council's action. It may be that it is their intention not merely to ascertain the likelihood of a profit in a renewal and improvement of the steamboat service, but to exploit the bolder idea of municipal enterprise. The prominent part taken by Mr. John Burns in the matter lends plausibility to this surmise, and it is also possible that the recent attempt of the directors of the Tramway Company to re-invest the capital of their shareholders in the steamboats, instead of paying to them the purchase money lately received from the County Council, may have suggested this view to the member for Battersea. The shareholders were wise in preferring hard cash to so speculative a venture. But much as we are inclined to deprecate the tendency to municipal socialism even in the working of tramways, we might be tempted to control our antagonism as ratepayers, and to criticise more tenderly a scheme for County Council steamboats if by that means alone the Thames were to be saved to us as a highway. We shall look with particular interest to the report of the Committee, and on the sequel.

◆◆◆

THE CLYDE ENGINEERING DISPUTE.

WITH the resumption of work in the shipbuilding yards of the Clyde after the New Year holidays—during which, of course, matters did not assume any new development—the idleness and dislocation in the engine shops have again become subject of anxious attention. It was expected by the engineers on strike that some non-union men would ask for employment, and pickets were on duty when the shops opened on Monday. However, their intervention was not required, as very few non-society men were to be seen near the gates. It is still apparently a moot point whether or not the masters really wish to employ non-union men, but it seems to be the case that in one or two instances preparations have been made which can only be explained on the grounds that non-union workers are expected, and that if any such apply to the foremen they will be engaged, provided they are eligible workmen. The apprentices in the Greenock and Port-Glasgow shops resolved during the holidays not to start work but to "stand by the men," and this they did for one day, but have since gone into their several shops. In Glasgow also there has been a disposition among the lads to cease work, but so far this has not actually taken place. The effect of such a step, in any case, would not be very marked one way or another in this most grievous dispute, and serious difficulties might arise in connection with the reinstatement of the apprentices after settlement of the dispute. The destination of Mr. Sellicks, the president of the Amalgamated Society of Engineers, who left London on Tuesday of last week, was not Belfast, as stated in the course of our article in last issue on "Free Labour on the Clyde," but Glasgow. His presence there, and the speeches which he and the local officials of the men's society have delivered throughout the Clyde districts, have not been in consonance with the spirit of the season which is sacred to "peace on earth and goodwill among men." On the contrary, they have been calculated to embitter, if possible, the present strained relationship between employer and employed, and to close still more firmly the door against conciliatory advancee. At one of the meetings the following resolution was proposed and unanimously carried :—"That this meeting of locked-out engineers and taxpayers bring under the notice of the Admiralty the criminal neglect and delay of the Clyde employers with regard to the completion of the national contracts." With regard to this, of course, the employers feel that it is a case of the pot calling the kettle black. The men are not entitled to describe themselves as a meeting of "locked-out engineers and taxpayers;" they are simply engineers on strike against what by very general consent is regarded as a fair enough offer for the settlement of a trade dispute. To accuse the employers of "criminal neglect and delay" because they refuse to do absolutely what the workmen demand is manifestly absurd, especially in view of the fact that the Executive Council of the men's society have still made no counter proposal to that which they rejected after the Glasgow conference. At present the society stands before the public as refusing all conciliation and rejecting all negotiation, and in that light they are more to blame for "criminal neglect and delay" than the employers.

THE RACE TO THE NORTH.

IT has been freely stated of late that the Midland Railway Company has no intention of entering into the contest for the shortest possible run to the North. The reason given for this self-restraint in avoiding railway racing is that it is more concerned about the comfort and regularity of its service than in landing its passengers a few minutes earlier at Modern Athens, or Aberdeen-awa'. There is sense in this suggestion, but it is not to be inferred from what has been said that the Midland directors are at all asleep. It is a large company, and although it may not be over-anxious to accelerate its expresses to phenomenal speeds, it is seeking in other ways to lessen the time taken in doing the run from St. Pancras to Scotland. It is certainly not behind other companies in providing powerful means of traction of the most efficient type, or in combining the maximum of safety with the minimum of lightness in the rolling stock. But it is at present contemplating quite as important a contribution to a quick northern run as in either of these directions. Our Sheffield correspondent has drawn attention several times to the new line the Midland Company has constructed from Wincobank, near that city, to Chapeltown, and pointed out the importance of that line, not merely to the district it serves, but as the first link in an alternative route to the North. The Midland is now continuing the line from Chapeltown to Barnsley. It has struck many people that the Coal Capital could not possibly be the terminus of this extension, and the directors themselves must have had it in their heads to carry on the rails so as to join the main line at some point at or near Bradford. If this were done not only would there be direct communication, which does not now exist, between Sheffield and South Yorkshire and Bradford, but the Midland route from London to Carlisle would be the shortest by nearly twenty miles. This part of the Midland main line, through the heavily populated manufacturing districts it traverses, is usually in a crowded and congested condition, and the fresh extension to which it is now being urged would relieve the Midland of this difficulty and put it right to the front in the struggle for the coveted Scotch traffic. Several deputations from various towns and districts concerned, representing Halifax, Huddersfield, Barnsley and Bradford, have recently waited upon the Midland directors, who, after hearing the statements put before them, have intimated that the proposals will be most carefully considered and the decision of the Board communicated as soon as possible. The people of Brighouse are anxious for the Midland directorate to adopt a counter scheme, the chief feature of which is a connection from Barnsley passing through Bilton, Bretham, Willsden, and joining the main line at Bentley. To effect this object the Brighouse Corporation are sending to Derby a distinct deputation, and are now endeavouring to get the Corporation of Huddersfield to take up their alternative proposal. In any view of it the prospect opened out by the extensions from Barnsley appears most inviting, and the expectation in the district is that the Midland directorate will not readily ignore it.

LITERATURE.

Bulletins of the California State Mining Bureau. No. 2, *Methods of Mine Timbering*, pp. 58. By W. H. STORMS. *No.* 6, *California Gold Mill Practice*. By E. P. PRESTON, pp. 85. Sacramento, California. 1894-5.

IN addition to the usual annual report dealing largely with statistical and administrative matters, the present State Mineralogist of California, Mr. J. J. Crawford, has introduced the practice of publishing special memoirs upon subjects of technical interest; the titles of two that have reached us are given above. They are both of considerable interest, as containing much orginal detail, the result of personal observations by the authors, and therefore of value as supplementing the larger general treatises, which are apt to become a little antiquated as regards newer developments. Mr. Storms' paper on "Mine Timbering" gives numerous illustrations of the heavy system of frame timbers used both in the lode and drift gravel mines of California, and their development from the old post and lintel systems to the square set methods introduced by Deidesheimer in the Comstock mines in 1860. This system, although of great service in its day, is likely to become less useful in future, mainly on account of the difficulty of obtaining timber of sufficient size. Even in a wooded country like Northern California, timbers 24in. by 28in. are becoming scarce. In the future of deep mining we may therefore expect that methods based upon the use of bearing arches of rock and masonry, with waste rock packing, will be likely to take the place of timber in the securing of workings from large deposits.

Mr. Preston's paper, besides containing a description of the construction of stamp mills and their accessories, gives a very convenient compendium of the present practice of gold quartz reduction by stamping and amalgamation as carried out in different parts of California, with ores varying greatly in richness and mineral associations. This is contained in a series of notices of nineteen different mills on pages 64 to 77, each representing some special peculiarity. Particular attention is given to the arrangements for collecting and saving valuable material from tailings. The economic results obtained by these arrangements is in some instances very remarkable, as, for instance, at the Spanish Mine in Nevada Country, where ores yielding about twenty-one grains of gold per ton are mined, and milled in the Huntingdon Mill at a total cost of about 2s. 1d. per ton, leaving a surplus of about 1s. 6d. per ton; and Mr. Crawford has done good service in causing these treatises, which are commendable among other good qualities for their brevity, to be prepared and circulated. In connection with these publications, we notice a curious instance of the desire for local protection which has become so strongly developed in America of late years. Copies of the gold mill paper may be obtained by sending three cents for postage, if the sender is a citizen of the State, but to those living outside the State of California the price is 50 cents; and this discrimination is established not merely against foreigners, but also against the 50 millions or so of Americans who are not Californians. However, even at the higher price the purchaser will get good value for his money.

Vergleichende Versuche über die Feuersicherheit von Speicherstützen. 4to. 84 pp. with 17 plates. Hamburg: Otto Meissner. 1895.

THIS is the report of a Technical Commission appointed by the Senate of Hamburg, after the disastrous fire in April, 1891, when the State Granary on one of the principal quays was destroyed, for the purpose of investigating the fire-resisting powers of iron and metal pillars used in warehouse construction. The plan of experiments was arranged and commenced in August, 1892, when the outbreak of cholera, calling for the services of the members in other directions, led to their suspension for nearly a year; but they were resumed and concluded in the period between July and October, 1893, the final report being dated October, 1894. The objects experimented upon were full-sized examples, 18ft. in length, of the lattice-framed iron pillars used in the Hamburg Harbour Warehouses, which were maintained in a vertical position by hydraulic pressure acting from below against a cross beam overhead, the pressure being regulated to the amount representing that of the fully loaded warehouse floor, or from 115 tons to 180 tons for the iron, and 60 tons for wooden piers. Heat was applied, nearly at mid height, by a closely fitting gas furnace with eight burners, and continued until the bearing power as indicated by the pressure gauge of the hydraulic press was exhausted. The temperature attained was observed by a pyrometer, and the lateral deformation during heating, as well as by one sided cooling, were determined. The metal pillars were tested with the lattice work open and filled with concrete, and also with different kinds of fire-proof casing, including plaster slabs, cork composition, xylolite, Monier concrete, and asbestos cement, and the wooden ones with and without similar protecting casings; and the results obtained are fully described, with numerous illustrations reproduced from photographs. The general conclusions show that malleable iron pillars have very small fire-resisting powers, their stability being entirely destroyed at a temperature of about 600 deg. Cent., and the advantage to be gained by an internal filling of concrete is so small that it cannot be considered to be of any protective value. It is different, however, with external casings of fire-proof or bad conducting materials, which may protect the metal against being dangerously heated for a considerable time, and so afford a notable protection in case of fire. The protective materials that have proved most efficacious are the patent cork composition made by Gunzweig and Hartmann, of Ludwigshafen, and xylolite slabs with an outer casing of sheet iron. This gave off inflammable gases for 2¼ hours, and became completely carbonised, giving a covering that was not affected by the jet from a fire hose. The pillar did not give way until the heat had been applied for four hours, while from seventeen to thirty minutes were sufficient to destroy it when it was without a protective casing. Next in order was a 40-millimetre casing of Monier concrete, which held out for 2½ hours; but other substances, such as ordinary and hard plaster slabs and asbestos cement, proved to be of small value.

The experiments with wooden piers show that, although they ignite at a lower temperature than 600 deg. Cent., they maintain their carrying power longer than unprotected iron ones; but no advantage is gained by casing them with sheet iron. Oak piers seem to be slightly better in fire-resisting power than those of fir.

The report is accompanied by a series of appendices, the most important one being that containing extracts from the records of the observations, with several typical examples given at length. These, together with the accompanying illustrations, give a very clear idea of the character of the evidence upon which the conclusion of the report is founded. The Commission, which was presided over by Mr. F. Andreas Meyer, the chief municipal engineer, point out that their report is necessarily incomplete, many important points of warehouse construction not having entered into the scheme of experiments, which was, no doubt, limited by the funds available, but within these limits they have supplied information of considerable value to architects and engineers, and thanks are due to the Senate of Hamburg for their liberality in publishing and circulating the results.

The Locomotive Engine and its Development; A Popular Treatise on the Gradual Improvements made in Railway Engines between 1803 and 1895. By CLEMENT E. STRETTON, C.E. 4th Edition, revised and enlarged. London: Crosby Lockwood and Co. 1896.

IT is barely a year since we reviewed the third edition of Mr. Stretton's excellent work, and it must be most gratifying to him that a fourth edition is required after so short an interval. Mr. Stretton has responded to this demand by producing what is in a large degree a new work, so greatly is it enlarged and improved in this new fourth edition. In addition to copious revision and supplementing of the original text, the author has added twenty pages of entirely fresh matter, and fourteen new illustrations. The work is brought thoroughly up to date, even the new express engines just brought out by the Manchester, Sheffield, and Lincolnshire Railway Company, Great Western Railway Company, and London, Brighton and South Coast Railway Company, and those now building by the Midland Railway Company receiving due notice. In fact, a very clear and comprehensive account is given of the locomotive development of the year and of the general advance made. It is to be hoped that Mr. Stretton will see his way to bring out a fresh edition annually.

But, further, the author has expanded and improved that most interesting phase of his work, the early history of the locomotive. He gives much valuable information as to several points recently discussed in connection with the early engines of the Great Western line and some capital illustrations, including one of the original engines, Great Western, the first of the famous express engines which were the standard for the broad gauge until its final extinction in 1892, as it appeared after the extra pair of leading wheels had been added, but while it still carried the high-domed "haycock" fire-box. Another noteworthy illustration is that showing the details of construction of the curious 8ft. disc wheels of the engine Ajax, about which there has been so much controversy. There is also a great deal of new matter touching the introduction of bogies and other useful features in railway practice.

Nor does Mr. Stretton confine his attention to Great Britain. He has a large amount of important information to give and illustrate as to locomotive development in the United States of America. There is a good frontispiece view of the celebrated No. 999, and a picture of the new American single, No. 388, with various particulars of work done by various American locomotives. Among the curiosities of the illustrations of British engines may be mentioned one of the Great Western, Leopard, as it appeared after a burst, the boiler having exploded in 1857, owing to a defective safety valve.

One of the author's remarks regarding the mode of expressing gradients we cannot quite follow. He says, "In this country it is still the practice to express gradients in their proportion or ratio to 100"; that is to say, by their percentage. But this has not been usually the case in our experience, the proportion expressed being almost invariably the ratio to unity, or one, *e.g.*, a rise of 1 in 75, 1 in 80, 1 in 150, &c. The percentage method of expressing grades, *i.e.*, as so much per 100, is more used in America than in this country, though, as Mr. Stretton justly says, it is more usual in the States to refer to gradients by giving the rise in feet per mile.

Mr. Stretton's new edition is sure to be in large demand like the predecessors, and even those who possess last year's edition—the third—will find themselves almost obliged to procure the new one if they desire to keep up to date.

SHORT NOTICES.

Transactions of the Royal Scottish Society of Arts. Vol. xiv. Part I. Edinburgh: Printed for the Society by Neill and Co. 1895.—Contains amongst others, papers on a sun-dial protractor, an improved bucket pump, a direct reading micrometer wire gauge, and on the Ferranti electricity meter.

The Indian and Eastern Engineer Diary and Reference Book for 1896. London: 28, Victoria-street.—This is a quarto diary with three and four days on a page, on good paper, and interleaved with blotting paper. The diary is accompanied by eighty-four pages of quarto letterpress relating to trading information useful to those with business relations in India and other eastern countries, and it also contains a well-made selection of facts and formula for the use of the engineer.

The Third Annual Review of the World's Grain Trade, 1895. By Geo. J. S. Broomhall. Being a record of the world's chief cereal crops, prices, imports and exports, stocks, population, &c. &c. Liverpool: Northern Publishing Company, Ld. Price 2s. 6d., post free 2s. 9d.—This relates to cereals and to flour, and opens with an article on the international grain trade, past, present, and prospective. It is accompanied by numerous curves or diagrams showing fluctuations in prices, quantities, freight, of wheat flour and feeding stuffs generally. The article on international grain trade contains information of great interest in connection with the steamship transport of wheat and other grain.

The Export Merchant Shippers' Directory for 1896. Thirty-first year of publication. London: Dean and Son, Ld. Price 15s.—With this issue of the "Export Merchant and Shippers' Directory," a supplement in the form of a cloth bound itinerary of the City of London is given to every purchaser. It forms a very useful addition to the means of finding out the names of people, what they sell, and what are their markets. It is, of course, more particularly useful to those whose business it is to make calls on importers. The directory is, as usual, printed in clear type and divided into several sections, easily recognised before opening the book. It refers to about a dozen other large trading towns and cities besides London, their trading ports, and the class of goods shipped.

Donaldson's Engineers' Annual and Almanack for the year 1896. *A Record of Progress and Events in connection with Steam Shipping, compiled for the use of Marine Engineers and the Mercantile Marine, with Tide Tables and other References.* Paper. By James Donaldson. London: Norie and Wilson; F. Brett. Price 1s.—Besides the information which the title of this annual conveys or promises, it contains a large number of tables specially devised and arranged for the use of sea-going engineers. The position of engineers in the different navies, and regulations under which they work, are set forth, and our Board of Trade regulations for engineer examinations are given. The usual collection of tables of weights, materials, and measures, is followed by short articles on record passages, tales of the sea, harbour matters, and various things that will make the annual an engine-room companion.

BOOKS RECEIVED.

Annuaire pour l'An 1896. *Publie par le Bureau des Longitudes. Avec des Notices Scientifiques.* Prix 1f. 50c. Paris: Gauthier-Villars et Fils, Quai des Grands-Augustins, 55.

Dynamo-electric Machinery. A Manual for Students of Electrotechnics. By Silvanus P. Thompson, D.Sc., B.A., F.R.S. Fifth edition, revised. London: E. and F. N. Spon. 1896.

The Journal of the Royal Agricultural Society of England. Third Series. Volume vi. Part IV. No. 24. December 31st, 1895. To be continued quarterly. London: John Murray. Price 3s. 6d.

Elementary Treatise on Electricity and Magnetism founded on Joubert's "Traité Elémentaire d'Electricité." By G. C. Foster, F.R.S., and E. Atkinson, Ph.D. London: Longmans, Green, and Co. 1896. Price 7s. 6d.

Discoveries and Inventions of the Nineteenth Century. By G. Routledge, B.Sc., F.C.S. Eleventh edition. Revised and partly re-written, with additions. Containing 450 illustrations. London: George Routledge and Sons, Ld.

Lockwood's Builders', Architects', Contractors', and Engineers' Price Book for 1896. *A Comprehensive Handbook of the Latest Prices of Every Kind of Material and Labour in the Trades connected with Building, including many useful Memoranda and Tables.* Edited by Francis T. W. Miller. With a supplement containing the London Building Act, 1894, &c. &c. London: Crosby Lockwood and Son. 1896.

ALMANACKS AND CALENDARS FOR 1896.

A LARGE monthly tear-off almanack, mounted on an attractive and large background, has been sent out by the Rugby Portland Cement Company, additional interest being given to the almanack by a view of their works and a geological section of the country across England from Holyhead to Dover.

Messrs. W. H. Willcox and Co. also send a monthly calendar arranged so that the sheet giving each month may be turned back and leave the present month visible, the back months being retained for reference. The background of the calendar varies for each month with illustrations of the many forms of engineering requirements which Messrs. Willcox display.

The Magnolia Anti-Friction Metal Company have also sent a calendar with removable cards, making it, with a supply of three for each year, a perpetual calendar. The letters of the day and month are very clear, and the figure for each day of large size.

Messrs. Sankey and Son, of Canning Town, send a large monthly tear-off almanack, the background of which is illustrated by their various kinds of sanitary stoneware.

Messrs. Peckett and Sons, locomotive engine builders, send a nicely got-up monthly tear-off almanack, with an almanack for the year and various postal and other information printed on the back of the card carrying it.

Mr. John M. Henderson, stone-working tool and machinery maker, Aberdeen, sends a monthly tear-off almanack, and another is sent by the Sun Insurance Company.

The Hardy Patent Pick Company, Sheffield, also sends a very clear monthly tear-off almanack with white letters on blue background. The illuminated card to which this is attached contains a calendar for the year, a view of the company's now very large works, and references to their specialities in disintegrating, grinding, and screening machinery, mining tools, colliery vibromotor screens, and coal-washing, coking, and briquette plant.

INLAND NAVIGATION AND FOREIGN GOING STEAMERS.

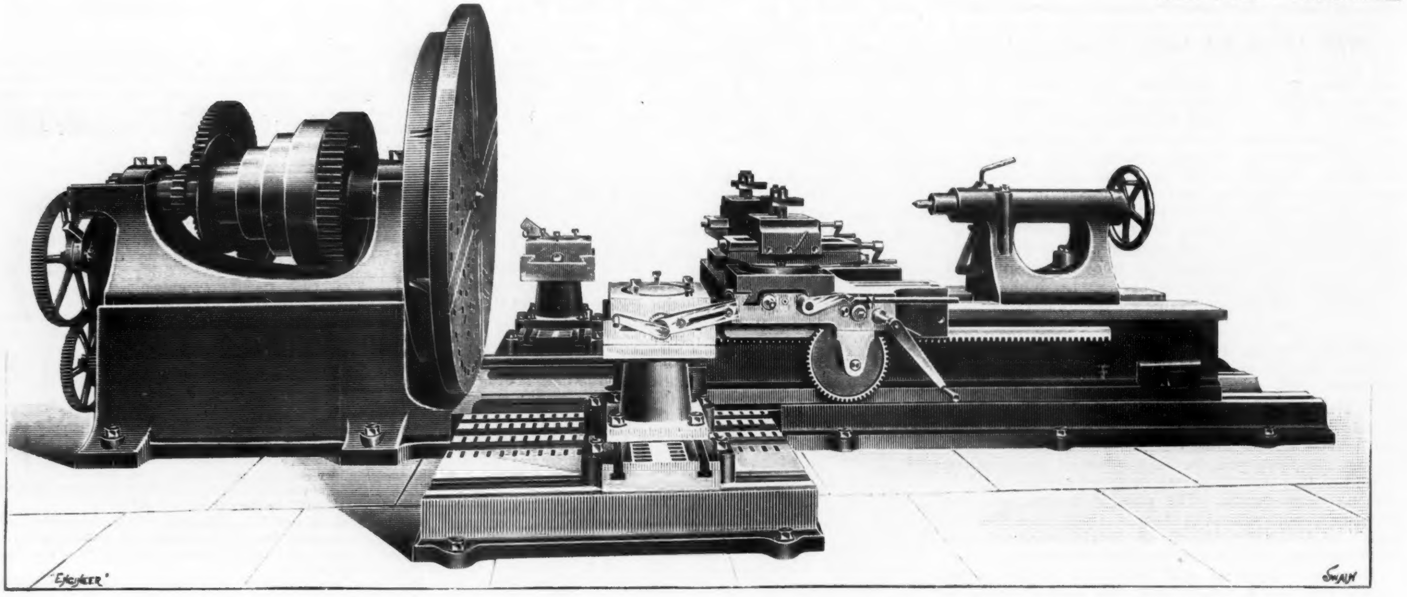
WITH the advent of the New Year an additional trading steamer, built for the purpose, has been added to the line plying between Manchester, Liverpool, Rouen, and Paris. The St. George, which is typical of the fleet, was built at Sunderland, is 600 tons burden, and supplied with engines of 650-horse power indicated. The masts and funnels can be lowered to the level of the upper deck. The traffic commenced eighteen months ago as an experiment with the s.s. Kenilworth, subsequently the s.s. St. Denis was built expressly for the service, and has been running six months. It is intended to add another steamer of the same capacity and build as the St. George shortly. This shows that the Seine and Mersey Steamship Company is satisfied with the present and hopeful for the future. Sea-going steamers ply regularly between London and Paris. Owing to the fixed bridges over the Seine, funnels and masts have to be movable, and even then the headway is much less than is desirable. The three lowest bridges are:—The Sevres Bridge, headway 22ft. 6in. above low summer level; the Conflans Bridge, headway 20ft. 6in. above low summer level; the St. Pierre d'Andé Bridge, headway 20ft. 1in. above low summer level. On the canalised Seine there is a traffic of 4,000,000 tons; 1,250,000 tons of this arises at Rouen. The whole is subject to railway competition, and is handicapped by distance, as between Rouen and Paris it is 137 miles by the river, which has an extremely tortuous course.

There is a minimum depth of 10ft. 5in.; in fact, the navigation is practically on a par as regards draught of water with the Weaver Navigation to Northwich and the Severn to Worcester. The Westgate Bridge over the Severn at Gloucester, however, provides a headway of only 18ft., 2ft. 1in. lower than the lowest of the bridges over the Seine, but this should not be a bar to sea-going steamers penetrating to Worcester, and thus getting within thirty-seven miles of Birmingham by canal. Moreover, there is always the hope that this bridge will be improved in the interest of the navigation. Since the navigable depth has been increased to 10ft. the reasons for altering the Westgate Bridge are much more cogent than before. To Northwich there is 60ft. clear headway over the Weaver, and space for transhipping cargoes into narrow boats, which can proceed thence by canal to the Potteries, about twenty-five miles away. At present the large traffic using the canal route is transhipped on the Mersey at Runcorn, Weston Point, or Ellesmere Port. Corn, however, is carried in barges of 200 to 300 tons from Liverpool to Northwich and sent inland by canal.

MARINE ENGINEERING DESIGN.—The Council of the Institution of Junior Engineers announce that arrangements have been completed for a course of six lectures on the above subject, to be given by a gentleman of long experience on the north-east coast, and now occupying the first position in the designing department of one of the leading London marine engineiring works. The lectures will be specially prepared to be of practical benefit to those attending them, the great importance of economical, as well as efficient design being kept in view throughout; and as there will be many questions considered affecting steam engine design generally, they will be of interest and value to engineers not exclusively engaged in marine engine work. The following are the dates of delivery:—From 7.30 to 9.30 p.m. on Monday evenings, 3rd and 17th February; 2nd, 16th, 30th March; and 13th April, at the Westminster Palace Hotel. Fee for course, 12s. Syllabus:—Lecture 1: Cylinders and Cylinder Fittings. Pistons and Piston-rods. Connecting-rods.—Lecture 2: Crank-shafts and Shafting. Main Bearings and their Frames. Thrust Blocks. Stern Tubes. Propellers.—Lecture 3: Condensers. Air Pumps. Circulating Pumps. Feed Pumps. Bilge Pumps. Pump Levers. Links, &c.—Lecture 4: Slide Valves and Rods. Valve Gears. Reversing Gears. Turning Gears.—Lecture 5: Engine Framings. Pipes and Pipe Arrangements. Stop Valves. Safety Valves. Expansion Joints, &c. Sea Valves.—Lecture 6: Boilers. Furnace Gear. Smoke-boxes and Uptakes. Chimneys. Lagging. Engine and Boiler Seatings.

SLIDING AND SURFACING BREAK LATHE

MR. W. ASQUITH, HIGHROAD WELL WORKS, HALIFAX, ENGINEER

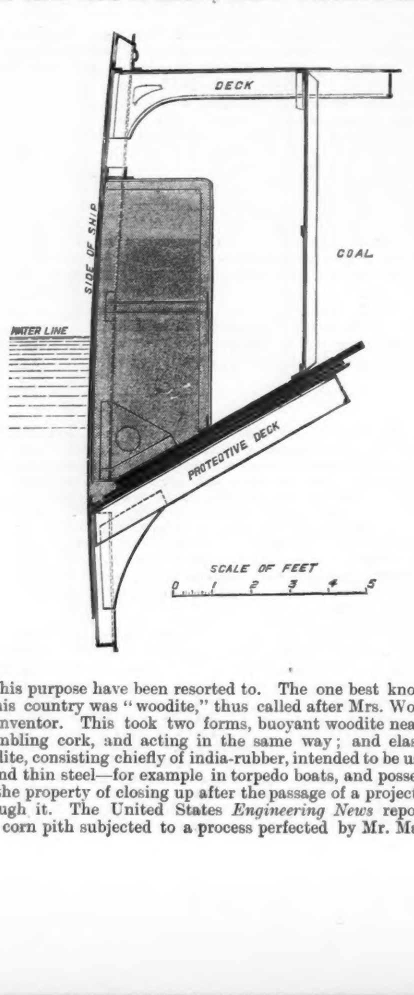


SLIDING AND SURFACING BREAK LATHE.

THE illustration represents an extra strong and powerful treble geared, 18in. centres, self-acting sliding and surfacing break lathe. The gearing in the fast headstock is machine cut, and so arranged as to give twenty-four changes of cutting speed, and the cone is suitable for a 5in. belt. The loose headstock is of strong construction, can be easily adjusted longitudinally along the bed by a carriage as shown, and has suitable provision for securely fixing it. The bed is of improved construction, the guiding slides being right angular, the carriage being fitted with loose gibbed strips, ensuring accurate adjustment and working with less friction and torsion than with the ordinary form of guiding surfaces. The carriage is fitted with two strong portable slide rests for general turning, the front rest being arranged with an improved self-acting motion for turning internal and external tapers. The improved self-acting sliding feed motion is positive, and can be stopped and started instantly by a lever on the front of the carriage. The bed is arranged to slide on the continuous bed-plate by power motion to form the break, and will admit 6ft. 6in. diameter by 4ft. 6in. wide in the break, on each side of which are foundation plates, carrying two saddles and pillars for receiving slide rests from the carriage. The lathe is of extra strong construction and great power, intended to do the heaviest cutting to advantage, and is capable of taking finishing cuts at the rate of 1in. traverse per revolution of spindle. The weight of the tool as illustrated is about 17 tons.

CORN PITH CELLULOSE FOR WARSHIPS.

FIVE years ago the question of packing the sides of warships with raft material was prominent, that is to say, the system of filling spaces with very light material, which would preserve floating power, inasmuch as there was no hollow space which could be filled by water. Curious substances for this purpose have been resorted to. The one best known in this country was "woodite," thus called after Mrs. Wood, its inventor. This took two forms, buoyant woodite nearly resembling cork, and acting in the same way; and elastic woodite, consisting chiefly of india-rubber, intended to be used behind thin steel—for example in torpedo boats, and possessing the property of closing up after the passage of a projectile through it. The United States *Engineering News* reports that corn pith subjected to a process perfected by Mr. Mark Marden has recently given capital results, acting in both ways to a certain extent, its weight when pressed as used being 6·5 lb. per cubic foot. This was compared with cocoa fibre cellulose weighing 7·7 lb. per cubic foot. The trial took place on June 10th last in the presence of Secretary Herbert. Two steel cofferdams 6ft. by 6ft. by 3ft. were used, the front plating was $\frac{3}{8}$in., and the back $\frac{3}{16}$in. thick. One was fitted with cocoa cellulose and the other with corn pith cellulose pressed in tight by screw jacks. A 6in. shot weighing 100 lb. was then fired through both, with a velocity of 1000 foot-seconds, after which each material appeared to close up the hole, water was then brought up over the holes. In about 10¼ minutes a drop of water found its way through the cocoa, and the water then flowed at the rate of nearly a half gallon per minute. The corn pith was subjected to the action of water rising to the top of the dam, perhaps 5ft. above the hole for 1½ hours; no water, however, made its way through.



An 8in. shot weighing 250 lb. was next fired through each cofferdam. On water being applied it began to get through the cocoa cellulose in 25 seconds, and then gradually attained a flow of 1½ gallons per minute, but failed to get through the corn pith for 45 minutes, when the test was discontinued.

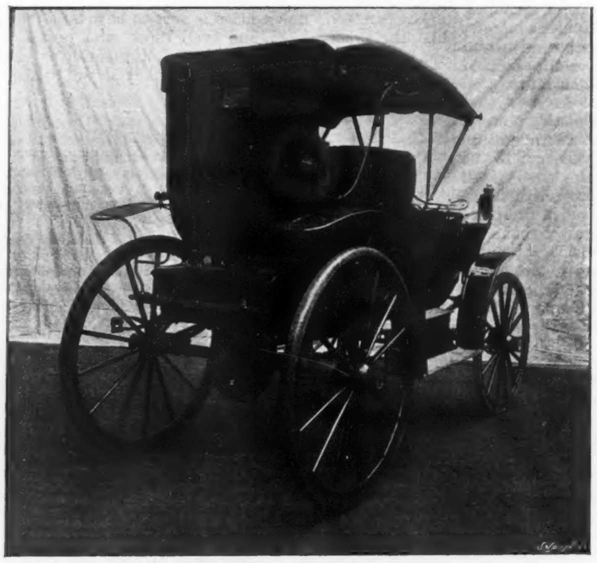
The combustible qualities of each packing were then tried by exploding a 3 lb. shell in an iron chest containing cellulose. The cocoa burned, but the corn pith was only charred.

On the faith of these trials, Secretary Herbert ordered corn cellulose to be used on the two warships "No. 4" and "No. 5." The figure herewith shows the manner of application to war vessels. Coals, are of course, often used in a similar way, and have the advantage of adding nothing to the weight of the ship, supposing the coals to be part of the supply carried for fuel, and coals have greater stopping power, we suppose. They have, however, the disadvantage of not closing up the shot hole.

EASTBOURNE WATER SUPPLY.—The Eastbourne Town Council recently decided to promote a Bill in Parliament to acquire the water supply, which is now in the hands of a private company. Opposition was raised by a number of ratepayers on the grounds of economy, and a poll was demanded. The result, which has just been made known, is as follows:—For the Corporation, 3527; against the Corporation, 3752; majority against, 225. There were 563 unmarked papers, many not voting because the ballot was not secret.

AMERICAN MOTOR CARRIAGES.

WE have received from our American correspondent the following particulars of the Benton-Harbour Motor Carriage Company's carriage, referred to, but not illustrated, in our last issue. It is a two-seated carriage for four persons, and has heavy rubber tires on the wheels. It is of a common and attractive design, fitted with a "hydrocarbon" engine of 7½-horse power, giving a maximum speed of 23 miles per hour on a good and level road. The motors are placed under the rear seat, and have no exposed chains or gearing, the driving gear being enclosed, as shown in the engraving. There are only two running gears, one of which is of raw hide to prevent noise; and only ten bearings in the entire carriage, all of which are fitted with $\frac{5}{16}$in. hardened steel balls running on tempered and ground steel cones, so that the friction is reduced to a minimum. A single horizontal handle pivoted to a shaft in front of the dashboard controls the brake, the change of speed, and the stopping, starting and reversing of the motor. The carriage weighs, complete, about 1050 lb. The inventor of this carriage has been experimenting with motor carriages since 1886. He first tried steam, and then electricity, perfecting a fairly practical storage battery carriage in 1893, but then turned his attention to the hydrocarbon engine, with still more satisfactory results. The company has a factory fitted up for the manufacture of these carriages.



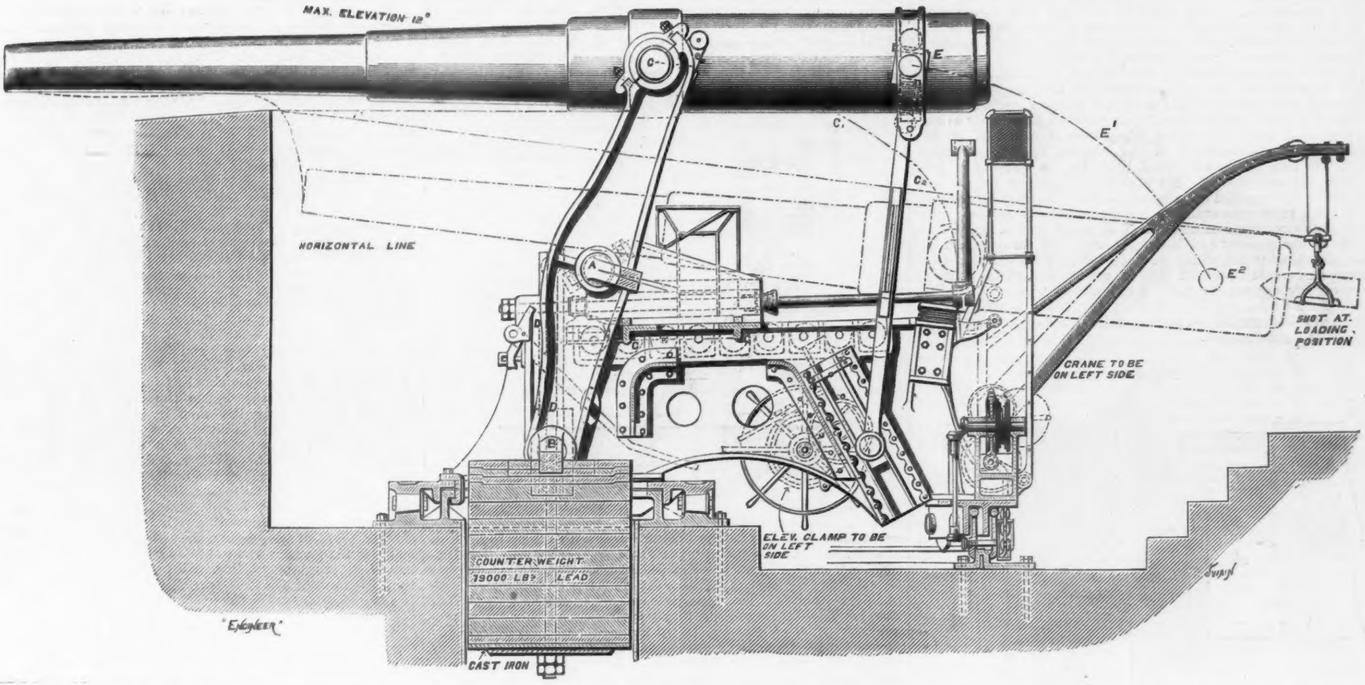
BENTON HARBOUR MOTOR COMPANY'S CARRIAGE

As regards the "Morris and Salom Motor Carriage," we may add that the carriage shown in our illustration last week was the one which made the run on November 28th, and it was awarded a gold medal "for best showing made in official tests, for safety, ease of control, absence of noise, vibration, heat or odour, cleanliness, and general excellence of design and workmanship." It carries forty-eight accumulators manufactured by the Electric Storage Battery Company, these being of 50 ampère hours capacity each, the electrical capacity of the battery being 5-horse power hours at the maximum discharge rate. The total weight is 1650 lb., of which the batteries make 664 lb. The maximum mileage on one charge is 25 miles—at 12 miles per hour—and the maximum speed is 20 miles per hour.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Chief engineers: George Ramsay, to the Vivid, additional, for the Blanche, from the day on which the Blanche pays off; George R. Taylor, to the Pembroke, additional, for the Alarm; and Samuel A. Screech, to the Swallow. Engineers: Edward A. E. Crowley, to the Tamar, additional, for Hong Kong Yard; and George W. Murray, to the Humber.

THE NATIONAL SKATING PALACE.—Hengler's Circus, Argyll-street, Regent-street, has been converted into a spacious and luxurious skating rink. The floor of real ice is made on a system hitherto untried on a large scale for this purpose. Messrs. Tyler and Ellis and Messrs. J. and E. Hall are the patentees of the system adopted, and the refrigerating machinery is that using carbonic anhydride. Over the floor are two galleries, the first being fitted up as a promenade, and the other as a restaurant. The whole of the interior has been decorated, and electric light is used throughout. Special interest in the success of the enterprise is taken by the National Skating Association of Great Britain, who have made the rink their headquarters. The building will be opened to the public in a day or two. Two sets of Hall's tandem compound engines with jet condensers and compression pumps are installed, one set easily doing the work. Shallow steel tanks are used for the ice floor, instead of other forms used elsewhere. For the water supply Messrs. Tilley and Son have sunk a well nearly 400ft. into the chalk. Three nominal 40-horse power locomotive boilers by Messrs. Davy, Paxman and Co. are employed, or will be when the large cold storage warehouses now under construction are completed. The work has been designed and carried out under Messrs. A. H. Tyler and J. S. E. de Vesian, Assoc. M. Inst. C.E. Mr. Cooper being resident under them.

THE BUFFINGTON CROZIER GUN CARRIAGE



THE BUFFINGTON CROZIER DISAPPEARING GUN CARRIAGE.

A DISAPPEARING carriage on a modification of the Moncrieff system has been designed by Colonel Buffington and Captain Crozier, of the United States Ordnance Department, and taken up by the Bethlehem Company, which has met a need and been adopted by the United States Government. It is shown in the accompanying illustration. The gun's trunnions rest in the upper ends of two long levers, one only of which, C A B, can be shown in the figure; pivoting at the centre A is the top carriage. A heavy counterweight slightly outweighing the piece is hung on a shaft connecting the two lower ends B of the levers. At A also a pivot or axle connects the two levers resting in a trunnion bed across the top carriage. The top carriage runs on rollers G G in the lower carriage or chassis. There are two hydraulic cylinders in the top carriage.

On firing, the top carriage recoils on the rollers, carrying the middle point or shaft of the levers on it. The lower ends of the levers are confined in a vertical groove D D, and as the top carriage runs back, each end B is forced up this groove, the combined action causing the upper end C carrying the gun to follow the curve C C^1 C^2, the breech travelling along E E^1 E^2, and the gun coming down to the position shown in dotted outline under cover of the parapet. This curve is calculated to withdraw the piece and lower it in the most convenient way, first clearing the crest of the parapet by the horizontal withdrawing movement, and then descending rapidly.

The energy of recoil and of the falling gun is partly absorbed by raising the counterweight and partly by the resistance of the liquid in the two hydraulic cylinders in the top carriage. The pistons of these cylinders are stationary, the rods passing through the forward heads, and being attached to two lugs projecting upward from the chassis. The rods are also produced through the cylinder heads, and rest in supports at the rear of the chassis. By thus producing the rods through the rear heads, an equal volume is drawn into the cylinder during recoil to compensate for the portion of the rods drawn out through the front ends; and the volume of the cylinder which is devoted to the liquid remains constant, the cylinders thus remaining always entirely full, with no danger of the leakage into them of air to mix with the liquid and reduce its specific gravity and resistance. The orifices for the flow of the liquid past the pistons are so graduated in size as to produce a constant resistance during the recoil.

To raise the piece to the firing position after loading, the pawls at the forward end of the chassis which retain the counterweight are tipped by means of handspikes, which are passed through two screw eyes serving as fulcra, and bear against the lower ends of the pawls. The greater preponderance of the counterweight causes it to fall, raising the piece and drawing forward the top carriage. The forward end of the chassis rests upon a ring of conical rollers whose centre is on the axis of the counterweight. The rear end rests through four wheels upon a traverse circle or racer track, the wheels being mounted in roller bearings to diminish friction. Traversing is effected by handles at the sides of the chassis acting on a worm gearing, drawing over a spocket wheel and chain, which lies around the near end of the traverse circle, and is fastened at the front, somewhat resembling the Cunningham gear known many years ago in this country. Pointing is performed with hand wheels acting on spur gearing and toothed racks, &c. Designs embodying the principle of centre pivoting are now completed.

The advantages claimed for this system of mounting are mainly economy and simplicity, combined with the protection of disappearance. Our English experiment with the Hercules attack of a disappearing gun is quoted, also the firing of an exposed gun charge at Shoeburyness and Eastbourne with small projectiles. Sir George Clarke's expression of opinion on the advantage of disappearing mountings is quoted, and it is urged that for this kind of mounting the design in question has great advantages over the Moncrieff carriages. It is claimed that the features of complexity of construction and delicacy of mechanism have entirely been got rid of—that the carriage is as simple as an ordinary barbette or broadside carriage. An 8in. gun carriage fired 47 rounds on trial without any injury. The hole for the descent of the counterweight might be diminished if the latter were made of lead instead of iron. The system gave very little trouble with reduced charges. The official report states that ten rounds were fired in 14 min. 42 sec. by a detachment of eleven men and one non-commissioned officer.

MEGASS AND REFUSE FURNACES.

By WILLIAM PRICE ABELL, Assoc. M. Inst. C.E.

THE use of megass as fuel in the manufacture of cane sugar has, during the past few years, largely owing to the increased cost of coal, become more general, and on many estates in the West Indies it has entirely replaced coal, of which 25 cwt. were formerly required for the production of one ton of sugar. During the years 1890-94, 520 furnaces were rebuilt in British Guiana, at a cost of about £50,000, the annual saving thus effected amounting to more than £100,000.

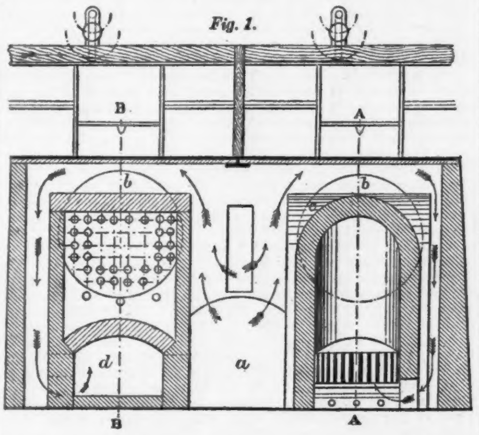
On the assumption that sugar-cane contains 12·5 per cent. of woody fibre, and the juice 16 per cent. of sugar, Mr. Nevile Lubbock states, as the result of many trials, that double crushing extracts 72 per cent., and single crushing 66 per cent. of the juice, leaving the green megass, composed in each case of woody fibre, water, and sugar in the following proportions:—

	Double crushed. Per cent.	Single crushed. Per cent.
Woody fibre	45	37
Water	46	53
Sugar	9	10
	100	100

Exhausted diffusion chips reach the furnace composed of 60 per cent. of water, 0·44 per cent. of sugar, and 39·6 per cent. of woody fibre.

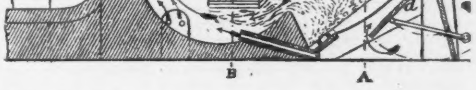
In the old furnaces, which do not utilise the oxygen and hydrogen in the water of the megass for combustion, it is calculated that 4·83 lb. of double-crushed megass and 5·98 lb. of single-crushed megass are required to give the same amount of available heat as 1 lb. of Scotch coal. Sir Frederick Bramwell and Dr. Letheby, in their report on the sugar manufactories belonging to the Khedive of Egypt, state that 2·09 lb. of sun-dried megass are equivalent to 1 lb. of Welsh coal.[1] From 100 tons of single-crushed cane are obtained 34 tons of megass, sugar, and water combined as fuel, 8½ tons of sugar, and 57½ tons of water to be evaporated out of the juice; and from 100 tons of double-crushed cane there result 28 tons of megass, sugar, and water as fuel, 9½ tons of sugar and 62½ tons of water to be evaporated out of the juice. With single-crushing, therefore, for every ton of sugar manufactured, 4 tons of refuse or megass, of which 53 per cent. is water, and, with double-crushing, 3 tons of megass, of which 46 per cent. is water, are obtained. This fuel, in modern though still imperfect furnaces, will evaporate 57½ tons to 62½ tons of water from the juice of 100 tons of cane, besides generating all the mechanical work involved in crushing the canes and manufacturing the sugar. A surplus of megass should be stored while the mills are working, so that it may be possible to manufacture with it the offal products after the grinding ceases.

Fig. 1.



The results of long grinding at a factory producing 1¼ tons of sugar per hour show that the amount of megass available per hour is 3·75 tons, consisting of 2·03 tons of fibre and 1·72 tons of water. This is burnt in five furnaces, of which two are of the type shown in Figs. 1 and 2, and three are of the type shown in Fig. 3, 4·24 cubic feet of megass being thus available for each furnace per minute; but sufficient steam is maintained with 3 cubic feet per minute. Each furnace has a grate area of 20 square feet, and each supplies heat to a multitubular boiler containing 1300 square feet of heating surface. The chimney draught, as shown by a Bailey draught gauge, is 40ft. per second; the flue temperature, as shown by a Bailey pyrometer, is 500 deg. Fah.; and the furnace temperature is such as to melt copper and partially melt cast iron about 2000 deg. Fah. The steam obtained from these five boilers and furnaces concentrates and purifies 9·45 tons of juice into 1¼ tons of pure yellow sugar per hour. The boiler pressure is 75 lb. per square inch, and the cane is crushed at the rate of 13·2 tons hourly, 3·75 tons of megass and 9·45 tons of juice being produced—the latter consisting of 1·25 tons of sugar, and 8·20 tons of water and offal. In addition to extracting juice from the canes with a pressure of 250 tons on each of the top rolls, the water is evaporated, the sugar is cured, and the molass is converted into rum and second sugar. The 3·75 tons of megass develope the requisite power without the assistance of any other fuel, the duty of the engines employed amounting to 463 indicated horse-power, and the heating surface in the evaporators being 5650 square feet.

Fig. 2.



The water in megass was, until a few years ago, evaporated in the furnace and driven out of the chimney as waste steam. In some cases the megass was dried in the sun or in logies, on the theory that to employ water as fuel was to use more energy than could be realised from the combustion of the oxygen and hydrogen obtained from its decomposition. Ordinary megass, if burnt in the usual way, scarcely produces heat enough to promote its own combustion. The result of the improvements in furnaces has been that condensed steam or white smoke is seldom seen issuing from megass chimneys. Green megass may be taken to consist of 50 per cent. of fibre and 50 per cent. of free water, the small quantity of sugar and ash present being negligible. The chemical analysis of the substance is:—

Fig 3.

	Per cent.		Per cent.
Carbon	25·00	Woody fibre	50
Hydrogen	2·78		
Oxygen	22·22		
Hydrogen	5·56	Free water	50
Oxygen	44·44		

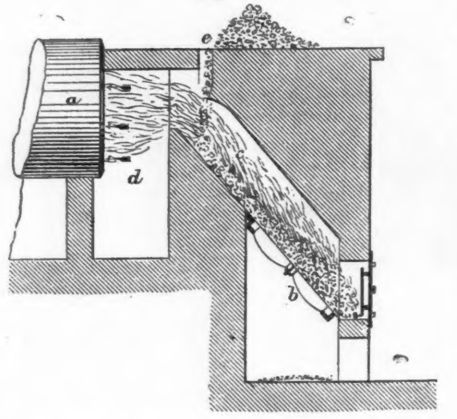
---

[1] See also "Minutes of Proceedings," Inst. C.E., vol. xlviii., p. 87.

Megass thus contains exactly the amount of oxygen necessary or the complete combustion of its carbon.

When hydrogen and oxygen exist in a compound in the prope ratio to form water, its constituents have no effect on the total heat of combustion. This would be the case with woody fibre in megass under ordinary circumstances, when burnt in the older type of furnace. On the other hand, in a properly designed green-megass furnace, when thoroughly heated, the water, in the form of aqueous vapour, is decomposed in passing over the highly incandescent and porous carbon of the megass; oxygen is liberated and combines with the carbon to form carbonic acid; and the hydrogen passes off partly uncombined, and partly as carburetted hydrogen. The latter, in presence of sufficient oxygen and at the high temperature of the furnace, undergoes further combustion and yields additional heat by its conversion into carbonic acid and water. This is shown in practice by the fact that little air is required for a furnace after it is properly started. If the pores of megass could be impregnated with air and saturated to the required extent, each atom of carbon being contiguous to the necessary air before the fuel was thrown upon the grate, the result would differ from the ordinary smouldering combustion, and would approach that of gunpowder, which contains the necessary oxygen for perfect combustion without air. The fuel should first be gasified and then burnt, the moisture being split up and the oxygen and hydrogen used for the combustion of the carbon in the megass.

Fig. 4.



In an efficient megass furnace perfect combustion of the gases and carbon flecks should be produced, the gas being first liberated and then consumed, so that no white vapour escapes from the chimney. It should require no increase of chimney height, and should work without forced draught. The temperature in the combustion chamber should be sufficiently high for the production of water-gas. Ample provision should be made for expansion through large and varying ranges of temperature. Furnaces have been constructed in which the waste heat from the chimney is utilised for drying the fuel on its way to the fire-box. Experiments made by the author in 1887, however, showed that with a flue temperature of 550 deg. Fah., a layer of megass 3in. thick took forty-five minutes to dry.

In Fig. 4 is shown the Alfred Fryer furnace, introduced in 1883 by Mr. Maurice Costa, and adopted with success in British Guiana. The grate *b* is inclined with the lowest part at the furnace front, and the green megass is introduced between the bars and boilers *a*, so that all the flames pass through and over the green fuel on its way down the drying plane *c*. The megass is introduced at the opening *e*, and, falling on the inclined drying plane, it gravitates downwards on the fire-bars, as that below it is burnt. The whole of the products of combustion pass up over this drying plane and there evaporate, taking up much of the moisture of the megass. The flames then pass the feed-mouth into the combustion chamber *d*, and finally into the boiler. No air was observed to be drawn in at the feed-mouth, although the stream of flame was always plainly visible passing this opening, which measured 10in. by 5ft.

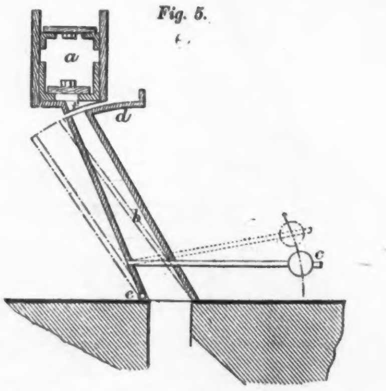
In 1890 the furnaces shown in Figs. 1 and 2 were introduced by the author. They are arranged in pairs, the air for combustion being drawn between the two furnaces at *a*, over the boiler tops *b*, and finally over the reverberatory arches $c\ c^1$ into the ashpit. The air is caused to pass the hottest or lower part of the fire-bars by the deflecting plate *d*, reaching the top end of the fire-bars and entering the megass at a temperature of 300 deg. Fah. The check wall or plate *e* regulates the thickness of megass on the fire-bars. In order to still further heat the air and facilitate the complete combustion of the gases and carbon flecks, a similar furnace, but possessing an additional combustion chamber, was introduced and gave highly satisfactory results. In 1892 the automatic feeding arrangements were added, with a view to reduce labour on megass platforms, to dispense with the gearing hitherto used in mechanical firing, and to give a constant and regular feed of fuel. They have proved so sensitive in practice that without any assistance they can supply one furnace with the exact quantity of megass, passing the surplus on to the next. The megass is carried the whole length of the platform by the usual rake carrier, connected with each furnace by enclosing hoppers. Down these the megass falls direct into the furnaces until the hopper is sufficiently full to cause the megass in the carrier to pass over that in the hopper. The surplus megass can either be discharged at the carrier end or be stored between each furnace by opening intermediate doors under the control of the attendant. No firemen are required, except when the megass furnaces are not stopped owing to the mills ceasing work, in which case, by simply opening the door at the bottom of each enclosing hopper, the furnace can be fed by hand in the usual way. The attendant simply regulates the flue dampers to give the necessary steam, and adjusts the intermediate doors to prevent too much megass from accumulating at one place. He also sees, by means of the peepholes in the hoppers, that each furnace is taking its proper amount of fuel.

The apparatus shown in Fig. 5 utilises the weight of the megass to regulate its own feed. The hopper is hinged at *e*, *f* being an opening in the cross carrier, *d* a damper or sluice, and *c* a balance weight. The megass passes down the shoot *b* to the furnace until it is full, and then the weight of the megass, accumulating in the hopper, causes it to descend about the hinge into the position shown by the dotted lines, at the same time raising the balance weight and sliding the sluice or plate over the opening *f*, thus causing the megass to pass on to the next furnace.

In 1893 a furnace was tried by the author in which the fuel was passed through an open-ended retort projecting vertically into the combustion chamber. The flames of combustion heated this retort, and thereby heated, dried, and distilled the gases out of the megass ready for combustion so soon as they reached the combustion chamber, and solid partly dried fuel falling upon a hearth surrounded by four pigeon-holed walls. It was found advantageous to block up the pigeon-holes until only 7 square feet of grate area were allowed for burning 7 cubic feet of megass. The ratio was thus 1 square foot of grate area per cubic foot of megass, whereas it had previously been 6 square feet of grate area per cubic foot of megass burnt per minute. In other words, with a boiler having 1300 square feet of heating surface, the furnace having one-third the usual grate area, the amount of steam obtained from double the quantity of megass was three times that derived from similar boilers with ordinary furnaces in the same battery, and this with a natural chimney draught of 40ft. per second. The construction of the furnaces required only about half the number of bricks of ordinary furnaces.

The loss of megass, and particularly of diffusion chips when charred and partly burnt, is considerable, on account of the unburnt carbon flecks. These are similar in appearance to the end of a charred match, and are carried through the furnace and up the chimney unburnt in such quantities that on a still morning the ground round a sugar factory becomes strewn with them to a depth of some inches. To prevent the waste from this cause, a centrifugal combustion chamber—Fig. 3—has been successfully adopted for retaining the carbon flecks until they are distilled and completely consumed. The megass enters at *e* and falls to the fire bars *b*. The flames are led into the combustion chamber *d*, tangentially at *g*, so that the heavy unburnt particles are speedily separated from the light gases by centrifugal force—the heavy sparks and carbon flecks flying off to the circumference, and the light flames of combustion finding their way through the centre *g*, up the flue into the boiler *a*. The same arrangement has been applied with success to the retort type of furnace, wherein the combustion or whirling chamber is arranged above the hearth, around which are fixed tangential tuyeres supplied with air, preferably under pressure, from the chamber. The air enters the tuyeres and produces a whirling motion which causes the heavier unburnt particles of megass or chips to remain in the chamber, which is of large diameter, in virtue of their weight, whilst the lighter products of combustion pass up the deflector.

Fig. 5.



The economy of megass furnaces is still susceptible of great improvement, by the adjustment of the proportions in which the several constituents are consumed rather than by the introduction of new principles of construction or operation.

The paper is accompanied by several tracings, lithographs, and photographs, from a selection of which the figures in the text have been prepared.

THE ENGINEER IN NAVAL WARFARE.

WE give Lieutenant Edwards's second lecture. The *World*, commenting on it, says:—

The first lecture dealt with the work of the engineers in preparing the vessels for an active campaign. The second lecture tells of the actual combat as Mr. Edwards knows it might have been. Neither Mr. Edwards, when he delivered the lectures, nor Secretary Herbert, when, after long deliberation, he gave permission for their publication in the *World*, dreamed that the lessons which they taught might so soon be in danger of needing practical application. Of all the 70,000,000 people in this country and the 30,000,000 in England, not a baker's dozen had the vaguest idea that there was the faintest shadow of war between the two countries. Within a day the cloud burst, and as this second lecture of the series is going to press not only the 100,000,000 people of England and America, but a large proportion of the other civilised people in the world, are talking of nothing but the possibility of war between Great Britain and the United States. There will be a keener interest, therefore, in Mr. Edwards's lecture, which follows:—

"On the night of May 29th, the steam yacht Now Then, one of the mosquito fleet, steamed into the harbour of Vineyard Sound. She reported that one of the enemy's battleships and one of the heavy cruisers had been seen moving slowly to the eastward, accompanied by a torpedo boat, a steam collier, and one of the floating workshops. The two large vessels appeared to be in distress, for the torpedo boat moved constantly from the workshop to the war vessels. The Now Then had watched these vessels until dusk. She had to keep too far away from them to gather any definite information, but the ensign in command felt convinced that the enemy's vessels were bound either for Halifax or some point to the eastward, where important repairs were contemplated. This news was communicated to the Commander-in-Chief, who immediately congratulated the little scout on her pluck and good luck. The Chief-of-Staff was ordered to have the fleet leave harbour before midnight. The Admiral's face brightened as the Captain of the flagship pleasantly remarked that the little scout had a very suggestive name for a time of battle.

Condition of our fleet.—Our ships were in a high state of efficiency. They not only had clean hulls but full crews. The bunkers nearest the fire rooms were filled with selected coal; and to save the men from overwork this coal had been placed aboard and stowed by shore people. The several departments of every ship had a full supply of stores, sufficient not only for ordinary cruising, but for unusual emergencies. The crews were in excellent health, having had considerable rest, although standing watch and watch everywhere, except in the engine and fire-rooms. Under the peaceful shelter of the harbour highlands there had been no fear at night of torpedo attack. The men were therefore free of that intense strain under which the sailors of the blockading fleet were supposed to labour. There were no sick aboard, and as an almost perfect commissary system had been established, the crews were prepared for protracted and severe work. Dark clouds gathered on the horizon on the early morning of Decoration Day. While our sorrowful people were preparing garlands and tokens, to honour the heroic dead who had fallen in battle in the Wilderness, or on some such field as the bloody angle at Spottsylvania, the crews of the defence fleet were called to quarters and told to prepare for action.

Condition of the sea.—With the early dawn the wind and sea increased. It was particularly noticeable to the commanding officers that our men were somewhat superstitious concerning the result of a conflict on Memorial Day. The Admiral had anticipated this action, and in a general order had reminded our crews that grief was the forerunner of glory, and that if all did their duty Memorial Day would hereafter be associated in America with the greatest naval victory of the century. Early in the forenoon watch, the enemy's fleet was sighted to the northward, and appeared to be in readiness for action. Their numerous scouts and torpedo boats instantly steamed towards the shelter of the heavy battleship. The fleet of the enemy steamed to the south-east, and it was evident that if they accepted battle, it would take place some distance from shore. At this time there was quite a rough sea, and considerable wind, which materially checked the speed of the smaller boats.

Comparison of old-time frigates and modern battleships.—As our vessels approached the enemy and saw their powerful battleships, the old sailors were impressed with this fact, as expressed by a correspondent from Kiel, 'That modern navies cannot reproduce the glories of the ships of the line and old-fashioned frigates of Nelson's time. An old-time man-of-war, with her seas of snowy canvas, was a thrilling sight. A fleet of such vessels with sailors swarming in the rigging was a spectacle for gods and men. The modern battleship, with all its defensive armour and tremendous batteries, cannot be dressed for a holiday like one of the heavily rigged frigates of former days. It is a clumsy fortress in the water, without adequate facilities for decorative effect. It is an engine of war, a fighting machine, a marvel of engineering science, but with all the potency of its armaments it has not the same power of arousing enthusiasm which the old line ships have exercised in the past. And a modern fleet with its destructive engines and defensive resources lacks capacity for lighting up imagination. It is an immense combination of smoke-stacks, machine shops, engine houses, and ordnance factories, tricked out with occasional bunting, but deficient in spectacular charm and fascination.'

Preparations for action.—The crews had no need to be told that for the first time in the world's history there was now about to be waged a battle of machines; and that victory would come to that nation whose crews could handle and control the various engines of war with the greatest skill and for the longest period. A few weeks previous to the battle the engineers had been given absolute charge over the men in their department, but the demoralising work and influence of a decade of a faulty organisation could not be wiped out in a day. The fire-room watch repaired to their stations below, and soon the clicking of metal warned them that some of the hatches were being battened down by the carpenter and his mates. The Admiral in command realised that his success that day depended upon the efficiency of the machinery, and to prevent anything from falling among the moving parts of the engines the hatches were closed. Perchance many of the firemen who went down that day in their ships of war had some presentment that their coffins were being sealed when they saw some of the deck openings thus being closed. The ring of many a hammer was the death knell of some brave fireman and coal passer.

Appearance and condition of engineers' force.—The engineers' force presented a particularly fine appearance. Strong men, with intelligent faces indicative of character and loyalty, comprised this assemblage of mechanics and firemen. Always the neatest and best-dressed division of a war vessel, they realised the worth and importance of their own services in the impending battle. Many were continuous service men, and although they had the unqualified respect of their engineer officers, but few good conduct badges adorned their breasts. An inexcusable system whereby it was not the province of the chief engineer to recommend worthy men to his commanding officer for this honour had deprived these firemen of these desirable badges. Their commanders had respected them, too, but in the midst of the multiplicity of papers they had forgotten to reward the men working below. Coxwains-of-boats and captains-of-tops who were under the immediate observation of the executive officer, never failed to receive such recognition when deserved. With his quick eye and wonderful judgment the Admiral realised the condition of affairs, and then he spoke words of encouragement to these men. Machinists, firemen, and coal passers knew that this brave man regretted his neglect of previous years, and that at last the time had come when their work was appreciated. A cheer of joy and gratitude went out from the hearts of these firemen, and when it was taken up by the crew the Admiral was visibly affected.

Council of War assembled on all the ships.—The Admiral of the defence fleet had given orders that the executive officer, the chief engineer, the navigator, and the officers of the gun divisions, should, in council of war, be notified by the commanding officer of each ship of the plan and details of the proposed fight, as far as the movements and actions of each ship were concerned, so that, in the very likely case of the destruction of the interier communications, each of these officers could still act intelligently and in accordance with the prearranged plan. On this subject, it may be interesting to note the observations of the Commission of Inquiry on the French battleship Magenta. "Enclosed in the conning tower, assisted by a few picked men, the Captain's whole care will be the manœuvring of the vessel; he cannot see his crew nor cheer them by his presence and example, and can communicate his orders to them only by means of wires and pipes, the destruction of which, on their long circuit around the vessel, is open to many chances. If he has not, long before, given precise instruction to his officers; if these officers are not fully conversant with his ideas; if they have not, in their turn, instructed the crew in this respect; and if, finally, each man does not understand the details and importance of the part he is to fill, there will be, at the moment of combat, no assured communication with the Captain, and each party, shut up in a compartment of the vessel, will anxiously inquire what is taking place in the adjoining ones."—*Marine Française*, May 25th, 1895, 741.

Final inspection of the engineers' department.—The chief engineer and his assistants made a final inspection of the fire and engine-rooms. Provision had been made for getting the best work out of every machine, and they were in a most excellent state of efficiency. The men were kindly greeted and encouraged, and the example of their officers in going about their duties so quietly and unconcernedly inspired great confidence in the engineers' force. There was no piping of whistles and blatting of orders to men within speaking distance. The men were thoroughly posted in regard to their duties, and the watch bill had been so laid out that each man knew the extra duties he was expected to perform in case any should fall or become prostrated from the heat or overwork. Some spare tools had been placed within reach of the machinists, and all necessary stores were in accessible positions. The emergency watch made the rounds of the vessel and adjusted things where necessary. A final consultation was held with the commander of each vessel. It was recognised by the several captains that the man aboard ship who had to be resourceful, ready to assume responsibility, and peculiarly fitted for his task, should be the chief engineer. In this hour of danger he was not told that he was an idler and that 'aboard ship he was a non-combatant.' But he was reminded of the fact that his post was one of danger, and that upon the efficiency of his department would depend the result of the conflict. For speed is now a weapon in naval warfare, and he who controls it can look for victory. The chief engineer had no need to be told that when the fight was over and the crews mustered, it would be found that a greater percentage of the firemen than of the seamen would rest that night under the surging waves of the Atlantic.

Opening of the battle.—Gradually our fleet overtook that of the enemy. A flash of fire, a puff of smoke, the whizzing in the rigging of a projectile, and then commenced the historic battle of Chatham. From the time the first short was fired, the enemy made every effort to render the vessels of our squadron unmanageable. Shell were fired at the water line aft, with the hope that some fragment would strike a vital part of the rudder and screws, or some one of their attachments. To the great dismay of our Admiral, the Brooklyn was partially disabled in this way. It was found necessary to steer the vessel by means of her screws. Some of the hatches had been battened down, and the temperature of the engine-room had risen to 150 deg. within a half hour from the time daylight was shut out. The annunciator signals worked rapidly. Midway between the high-pressure cylinder and some auxiliary machines, the machinists stood at their posts working the engines to bell signal. The inspiration and encouragement given the firemen and coal passers by the officers in their tours of observation had much to do with the cheerfulness of the men.

They were not cheered by an occasional shout of victory which broke forth when one of the enemy's vessels seem to waver under some disablement, or when our Admiral complimented an occasional ship for her superb work. These brave artificers performed their duties with zeal and intelligence, but the strain upon them was intense. At times the seaman at the engine-room telegraph in the conning tower pulled the lever a trifle hard, and the index pointed to the line separating two different signals. The man on watch would have to decide quickly to which order he would respond. His judgment and common sense came into play, but it required great concentration of thought and immediate decision. Breathing an atmosphere partly saturated with steam—for the drain and relief valves had to be opened occasionally to the bilge under such circumstances—these men by their devotion to duty saved the ship. Before the fight was over one of the engineer officers fell in an apoplectic fit. And after the battle, when the excitement was over, one machinist and two oilers collapsed from the result of their terrible strain in manipulating the engines for nearly five hours. Within three months these men passed away, but their work on the day of battle had been glorified by a crown of martyrdom.

Disablement of the Massachusetts.—The enemy seemed to concentrate their fire on the battleship Massachusetts, that name recalling to the mind of their admiral the great part that Massachusetts had played in the history of our country. For a time it seemed as if this vessel had to contend against a division of our opponents' fleet. The skill and courage of the commander saved her more than once from being rammed and sunk. Two of our battleships and several cruisers were sent to her assistance, and relief was thus given her, but just before the enemy's squadron had been made to retire the Massachusetts sent up a signal of distress. The continuous shower of shell upon her armour, combined with the recoil of her own guns, had started the main stop valve joint on the starboard boiler of the after compartment. The escaping steam had driven the men from the fire room. One of the water tenders who had been fitting a new gauge glass near this valve chamber had been killed by inhaling the steam, and a part of the fire room force who had entered the bunker were missing. An engineer officer who had tried to prevail upon the men to remain in the fire room had been partially blinded, having groped his way midst the escaping steam to locate the impairment. Until he had found the cause it had been believed that an auxiliary steam pipe had burst. This officer had been pulled out of the fire room by a machinist, whose accurate knowledge of the fire room passage had made it possible for him to reach the water-tight door leading into the engine-room. The men from the other fire room in this compartment had been compelled to leave their station, the leak from the joint continually increasing. Communication with the other boilers had been cut off, but not until the pressure in the boilers of the other compartments had fallen. Brave men finally raised the safety valves and eventually from deck stop valves were closed. A good percentage of the men treated that day by the surgeons of the Massachusetts were found in the watch that had this casualty to battle with. The frightful roar of steam through the escape pipes disheartened the ships of our squadron, and once again the Massachusetts was made the centre of attack. Her gallant captain fell at his post, but the story of his fight is known to every schoolboy in the land. Like the Constitution and the Hartford, the Massachusetts will ever be regarded as one of our historic ships for the work she did that day.

Effect of the heavy sea upon the small boats.—There being considerable sea, the speed of the smaller vessels of both squadrons was materially reduced. The enemy, by having blockading work to do, had quite a number of transports, which at this time hampered them. Many of these boats put to sea. Followed by the Olympia, with her large boiler power, quite a number of these small craft were totally disabled. The heavy sea did not affect the speed of the large cruisers to the extent that it did the smaller craft. And our vessels, with their great boiler power, were not affected to the extent that the enemy was.

Efficient work of the emergency watch.—The picked men who formed the emergency division did excellent work on all the ships. Comprised, as this body was, of men who were resourceful and inventive, they were constantly in demand. The dexterity and skill shown by some of the boiler-makers in the use of hand tools astonished and delighted the commanders, and the jamming of the forward turret of the flagship was overcome by the rapidity with which the obstruction was cut out of the gearing. More than one disabled fireman was temporarily repaired by fitting straps over the defective part. By quickly fitting an alligator wrench to the spindle of its training gear, one of the large guns of the Indiana was again made to do service. The after smoke pipe of the New York was kept in place by the ingenuity with which eye bolts were secured to the rim of the upper section. The official reports of the several chief engineers and executive officers tell in detail of the incessant calls made upon this division, and the readiness of resource with which this picked body performed the many services required of them.

Efficiency of the triple-screw vessels.—The Columbia and Minneapolis with their great speed distinguished themselves that day, and forever silenced their critics. The numerous torpedo boats and torpedo chasers were gradually sunk by the shell of their rapid-fire guns. The result of this battle showed that vessels of 7000 tons, installed as the Minneapolis is, with a boiler power of 20,000 horses, in a rough sea will make quick work of a nest of small craft, and that the pirate type will play a specially important part in a battle between fleets. One of the nautical guerillas, in the shape of a torpedo boat chaser, disabled the starboard screw of the Minneapolis. With the two remaining screws this vessel made over 20 knots at intervals; she was easily steered, for there was comparatively little helm angle, and, disabled as she was, in connection with the Olympia and Columbia, she did magnificent work, chasing and overhauling the transports of the enemy after the battle. All during the fight the strain upon the chief engineers of the respective ships was beyond description. For years these officers had no power to reward or punish their firemen. The unmanly of the fire-room force soon found out that their comfort and convenience could best be secured by winning the favour of the executive officer, rather than by doing their duty at their stations. The duties of the firemen "were of the most arduous and disagreeable nature, very trying to health, temper, and discipline. Their management by the engineer officers was often a difficult task even in times of peace.

Insubordination in the fire-room.—When the stokeholds were closed on one of our ships, and the firemen realised that if any of the crew were to go down in their vessels there was no hope of escape for them, they insisted upon leaving some doors open, so that there might be some hopes of reaching the deck before the vessel foundered. The engineer officers had the doors closed, but not before shooting the ringleaders of the mutineers. These men apparently could not understand that an engineer must have absolute control over his men in action, and that isolated as he is, he must be ready to assume great responsibilities. The insubordination on this vessel in the fire-room, resulting from a vicious system, was the greatest stain upon that ship's good name and fame, and her sinking must be attributed to the demoralisation in the fire-room, for if that force had been effective she would not have been rammed.

Condition of the enemy.—From one of the engineer officers who was attached to the enemy's flagship, the following facts were gathered concerning the work of their corps of naval engineers: Even before they left Halifax, trouble had been found aboard two battleships and one of their fastest cruisers with their hydraulic piping. Night and day the mechanics had been at work overhauling the joints. The flanges had been smoothed, and where necessary caulking of the seams had been carefully done. The entire line had been repeatedly disconnected, and whenever possible easier bends had been substituted. Vegetable packings woven in a variety of forms had been tried, as well as the cup leather and metallic types. Incessant leaks had occurred, and up to the day the fleet had occupied Province-town, it had been impossible to move one of the turrets on the speediest battleships; for in repeatedly overhauling this vessel, several of the flanges had been cracked. No one in the fleet had been able to repair the damage, for the flanges had been secured in a special way which required the use of particular machine tools. Several of our own ships had some of the flanges of the hydraulic piping fitted in ways equally hard to repair, but fortunately our ships had been within a few hours' reach of repair establishments where a speciality was made of this kind of work. These ships had crossed the Atlantic just in time to encounter the equinoxial gales. From the day they took their departure from the Western Islands until they reached the American coast they had met continuous bad weather, and it is possible that the turrets and hydraulic outfit had in some way been impaired at the time. Several pinholes in the pipes had made their appearance, but this weakness had been overcome by fitting eye straps over the defects. Under a pressure of 600 lb., a stream would issue from one of the holes which had velocity enough to cut a person standing in front of it. A single hole was sufficient to imperil the system. Exceeding care had been taken with the cotton rubber packing of the joints, but it was found that from atmospheric or chemical causes, the material had lacked some of the advantages which it possessed when the plant was installed. It was impossible to prevent the joints from leaking a short time after pressure had been applied. Some trouble had been anticipated with this piping, for about ten years ago one of the enemy's most powerful vessels had met with a similar disablement in the Far East. Had not the enemy this difficulty to overcome in two of their battleships, the Massachusetts would probably have been sunk after the accident to her stop valve chamber. Our admiral was not altogether surprised at the news, for he well knew that it had been found necessary to renew the piping of the Monterey, and that experts had to be sent from the Washington gun foundry to overhaul the joints of the Amphitrite's hydraulic gun gear after she had been months in commission.

Impairment of the fans.—On one of the ships having a closed fire-room, serious results occurred from the stoppage of the fans. The fine dust from the floor plates was carried into the bearings and crank pins of the blower engine, and at one time three-fourths of the fans were not in use. The repeated bell signals from deck compelled the artificers to give their attention to the working of the main engines. The overhauling of blower engines had, therefore, to be done very hurriedly. Orders having been received to force the fires, the blowers were speeded up again. Water having been carried over, the result was a breaking down of the plant. It was not long before the vessel's speed was reduced, and this magnificent ship, from which so much was expected, cut a sorry figure in the fight. Better luck was had on those ships having the 'closed ash-pit system.' The experience acquired in this battle showed that the blower engines should not be made so light that they will not stand hard usage and slight neglect.

Very inefficient firemen in enemy's transport service.—The enemy laboured under the great disadvantage of not being able to maintain a sufficient and trained fire-room force. Their stokeholds were filled with firemen and coal passers who were inefficient by reason of their age and inexperience. They were practically boys who had been recruited from a class which had never worked in vitiated atmospheres, and when compelled to do duty in a stokehold heated to a high temperature they soon collapsed. These youths could not do the work that had been performed by the Chinamen who had formerly done the stoking. Our ministers at Peking and Tokio had urged the respective Governments of China and Japan to forbid their citizens entering the service of the enemy, and this request had been complied with. This seriously crippled their transport service, and materially lessened the efficiency of their merchant marine. The Engineer-in-Chief of the enemy's service had pleaded almost to desperation that the declaration of war be delayed until at least partly trained firemen could be secured for the transports. It was absolutely impossible for him to reason with the incompetent officials of the Admiralty. They thought that they knew more about firemen than he did. They told him that by his very nature, training, and education he was incapable of looking at matters beyond his department. He was also told that his efficiency, if necessary, must be subordinated to the good of the service. This platitude and truism had no application to his request, but in connection with the slur upon his profession it was expected to silence him. It was a costly error to that great nation to rebuke this able man, for if his advice had been taken the result might have been different. This man knew the bulk of the great carrying trade of the world had been done in vessels with Chinese firemen, and that if they were suddenly removed there would be no trained substitutes available. Of all the steamship companies that enter the ports of the Far East, only three have European firemen, and even these companies have Coolies assisting the white stokers. There are over sixty lines of vessels trading with these ports, so that it may be said that in one hemisphere there are practically no ships with a European fire-room force. Five-sixths of these lines have Chinese firemen, and some of the stokeholds are so hot that white men cannot work in them. For years the weakness of our enemy in this respect had been known to marine engineers, but their warning had been ignored. The study of the tactics of preceding centuries had a greater charm than the solution of an important engineering question. 'Remove the Chinese from the stokeholds of our vessels and the carrying trade of the Far East passes from our control forever,' said an European marine superintendent, who had lived over a score of years in China. This man knew that it would take them five years at least, and probably ten, to supplant the Chinese stokers by a trained force of competent firemen. There are men who believe that the task would be impossible, for the Chinese stokers live in heated stokeholds where Europeans would collapse. The firemen of the Transatlantic greyhounds are compelled to lay off at least every third trip; and to keep them up to their work they are supplied with a most nourishing diet, as well as commodious quarters. These Chinamen had simply to be prevented from entering the merchant-marine service of the enemy, and their commerce received a blow which was more than serious. The Japanese have a full realisation of the aid rendered England by the stokers of the Middle Kingdom, and one of the ways the Asiatics are going to secure the commerce of the China sea is by cutting off this supply. A distinguished Russian officer told me that in case they ever had trouble with Great Britain, one of the first things to be done would be to drive the Chinese out of the English fire-rooms. If no other method could be found they would declare such men pirates, and hang them upon capture. In this way, he said, we will cripple their transport service, and drive much of their commerce from the ocean. I was also told by an able English editor that the removal of the firemen would so impair the speed of their boats that the insurance rates would run up so high that a good percentage of the ships would have to tie to their docks. This fire-room question was a momentous one to our enemy working far from their military base.

Shore firemen inefficient at sea.—The most skilled firemen had been sent to the war vessels, and this left a comparatively untrained force for the transports. It was noticed that the firemen who had previously worked around boilers in shore establishments were not efficient men at sea. They were good water tenders and possessed some skill in firing, but the great heat and limited room for working the furnaces seemed to unnerve them. It was almost impossible to make them stand up to their work. On shore the boiler houses were large, and there was room for all manner of appliances which somewhat lightened their work. The older the shore firemen the more unsuited they seemed for the work required of them aboard ship. The experience of the blockading fleet, and particularly the work on the transports, showed the necessity of having some training school for firemen. Halifax not being a commercial centre, it was found difficult to secure men to replace any vacancies in the fire-rooms of the several vessels.

Condition of the enemy's firemen.—From the time our fleet had been sighted, the Admiral of the blockading squadron had hesitated in regard to engaging in battle. There was not a ship in his fleet which had a full fire-room force. There is not a modern man-of-war afloat which can do blockading duty for a month without a good percentage of the firemen breaking down. The men had given way under the intense strain of continuous work and the fear of torpedo attack. Boilers under steam for weeks, and worked irregularly, are bound to leak; and to keep up an engineer's department under such circumstances requires incessant work. It is true that these men had been assisted by mechanics from the repair ships, but the number of men that can be accommodated on such vessels must necessarily be limited. With each succeeding day the strength of the engineers' force decreased so far as numbers were concerned, and it was only because the blockade had to be maintained, and that time was diminishing the efficiency of the firemen, that the Admiral of the enemy's fleet consented to meet a squadron which was superior to his own only so far as the health and completeness of the ship's crews were concerned. One of the fire-rooms, aboard a certain class of vessel in the enemy's service, is known to their stokers as the "slaughter house." If it is so baneful under easy cruising, what will such a stokehole bring in time of war? In one of our types of vessels we have a fire-room which is not much better. How can the men be made to work in such a place? It is said that aboard the Yangwei at the naval fight of Yalu, "down in the boiler-room naked coolies shovelled coal for dear life, gin was as free as water to them, and whenever a man lagged he was urged on with blows from a thick club made of rubber belting. The draught was so intense that a continuous sheet of flame poured forth from the funnel." We can't drive our men in this way, but how are we to make them stand up to work that seems beyond their endurance? Here is the way Admiral Reveillere, of the French navy, would overcome this difficulty: "Let not the deck officers scorn to go below in the fire-room when the machinery is going at full speed. In time of war, when the engineer officers will be overworked and the firemen exhausted, it will be necessary to order below in front of the fires our strongest apprentices, in order to be able to give chase or to run. The young officers or midshipmen ought to be able to lead them there. There, where there is danger and fatigue, is the post of duty for the officer. Formerly we did not disdain to go out on a yard arm in bad weather. We should now be able to go in front of the fires when it becomes necessary to push the pressure above the limits of the boiler, either to capture or escape from an enemy. Let everybody on board be trained to fire regularly, and every one knows how much coal each furnace will burn at the greatest and at usual speed. The lowest boy used formerly to know how much the ship made by the wind or with the wind astern. Our crews have enough pride to attach the same importance to the speed of the engines, and not one of them will therefore dislike going below before the fires on the day of a fight, to take the place of the sick or the cripple." This reads beautifully, but the enemy with the best fire-room force in the world could not put such desirable recommendations into practice. A fireman is a skilled worker, not a strong labourer, and cannot be replaced so easily.

Weakness of the enemy's transport service when far from its base.—Heretofore the enemy had been regarded as a nation which had an unrivalled transport service, and one which was supposed to be sufficient for every emergency. Operating three thousand miles from home, and with an alert and aggressive opponent, was a condition quite different from that which had confronted them in previous years. The Columbia, Olympia and Minneapolis had captured so many of these boats that the protection of the transports was a matter of great concern to the commander of the enemy's fleet. It was recalled to mind that the Japanese required eighty transports to carry the same number of men that our enemy had. But the transports of Dai Nipon worked only 400 miles from their base, and were practically unmolested in their service. The ships of the Japanese were also coaled by people from shore. The enemy operating off the New England coast had to coal at sea. The Japanese practically did no blockading. The firemen of many transports broke down under the severe work exacted of them. With crowded decks they neither had the privileges nor the comforts heretofore given them. Our Minneapolis, Columbia and Olympia had no trouble in capturing the fastest of them. The transports not having done the work that was expected of them, the enemy's fleet went into battle with more than one vessel lacking a sufficiency of stores and supplies.

Disablement liable to occur.—During the action the engines of the several ships were used intermittently; not only at full speed, half speed, and at varying speeds of backing, but at progressing and decreasing speeds ahead. The machinery is built for such work, and with care should not suffer when subjected to such strains. But in time of excitement the men on watch will hear the telegraph signal repeated by startling orders from above, and in order to obey quickly valves will be suddenly opened. Starting up quickly will cause the boilers to foam, and if water gets in the auxiliary line of steam piping there is going to be trouble with some of the dependencies of the main engines. Some of our ships have single engines to drive their circulating pumps, and these are liable to become disabled if water is carried over. The same trouble can be expected from the independent air pump. These dependencies must be placed low in the vessel where they can easily be manipulated, and as separators, traps, and such contrivances are at times unreliable, their working will be seriously impaired when water reaches the pipes. There is another class of accidents which may happen for which the machinery should not be held responsible. I now refer to accidents caused by shot and shell, by torpedoes and by ramming. A shot or shell in the machinery space, a torpedo under the ship, or a good blow from a ram would probably disable the ship, and in most cases the only thing to do would be to get out. There are other incidents which may arise from shell bursting over battle gratings. Suppose a shell were to burst in the armoured portion of the smoke pipe, or just over the grating; the concussion or force of the blast might easily tear away some of the uptake and interfere seriously with the draught. Again, should a shell burst over some of the other hatches which must be open for ventilation, splinters from the shell would come through the gratings and might cut some of the steam pipes, filling the compartment with steam, and disabling a part of the machinery which was supplied by that pipe. It would not require much of a splinter to pierce the main steam pipe. This would disable, or rather might disable, the main engines, depending on whether there was more than one steam pipe and on how serious the accident was. These splinters might do other damage, but I do not think they would be likely to do much harm to the larger parts of the machinery.

Effort to disable our propellers.—The position of the propeller renders it liable to accident, and more than one ship was disabled that day from injury to the screw. Floating objects will break the blades and shafts of the propellers, and the machinery when subjected to unusual shock or strain may bring about the same result. Our enemy's commander-in-chief expended at least one fast torpedo boat in the effort to disable a screw of the Iowa's propeller. A bold attempt was also made, under cover of the smoke, to carry on the bows of a swift boat a wire netting which it was believed could be entangled in a wing screw of one of our large ships. All through the fight the disabling of a propeller of our battleships was a feature of the enemy's strategy. The Admiral believed that any battleship, with one of her two sets of engines disabled, and carrying a helm angle that materially interfered with her manœuvring powers, was little better than a cripple so far as offensive work was concerned. Our commanders, with their intimate knowledge of the currents off the New England coast, were able to manœuvre the vessels in such a way that, except in the case of the Minneapolis, their propellers were not disabled by the maritime pests in the shape of rapid small craft. The breaking of a propeller blade in itself may not be a serious casualty. If it is followed by irregular working of the engines and subjecting the machinery to shock, a broken thrust shaft may be the consequence. Losing a blade throws the engine out of balance, and machinery is then subjected to irregular strains. With a heavy sea prevailing and a propeller in this condition a fracture of the thrust shaft need not be surprising. Partly submerged objects in a narrow channel may do great damage to the propellers of war vessels by breaking off the ends of their blades. Our admiral had carefully warned the several commanders to look out for floating objects, and that the protection of the propellers was a matter of serious importance.

Mistake in having dynamos far removed from mechanics.—That policy of ours which placed the dynamo rooms as far as possible from the boilers brought distress to more than one of our vessels. The insulation of the wires has not been impaired on other ships by placing the plant within the engine or boiler compartments; and as we use the best insulated wire that can be purchased, it is fair to presume that we can do as well as other people in this respect. Our ships went into the fight with a long line of piping between the boilers and dynamo engines. That mysterious force which can be so well understood by the pupils of our naval engineers, but by some wonderful paradox is beyond the comprehension of the teacher, has its generator in a part of the vessel where the engine force cannot assist in its maintenance, and where skilled mechanics cannot put it in order when disabled. We paid dearly for this work in this battle. Very early in the fight two of the battleships had metal splinters disable the steam pipes of the dynamo plant. The concussion started the joints on another ship on the long line of piping on the berth deck, and in general we repeated the performance that took place at the Yalu, where every electrical device was out of order when the contest was over. The enemy had better luck with their electrical plant, for their dynamos and attachments were better protected and nearer the boilers. Their skilled artificers of the engine force supervised and directed the running of their dynamos, as the engines were within reach. Our machinists being in another compartment, could not assist when called upon for aid. The emergency watch, however, made temporary repairs whenever it was possible to do so.

Result of the battle.—This lecture simply tells of the responsibilities and duties of the Corps of Naval Engineers. It is not an account of that great naval conflict which was fought off the bold coast of New England, and wherein we gained that great victory which placed the laurel crown upon the brow of the greatest admiral that America ever produced. Our enemy was vanquished. From Bar Harbour to Block Island the coast was safe. When the story was told across the water, our enemy soon realised that with the best engineer force of any nation in the world, their steam department had brought their ships to grief. The disadvantages under which the engineers and firemen of the blockading fleet laboured, compared with those of our defence fleet, were too great to be overcome. There were no immediate reliefs to take the place of the sick and exhausted. There were no auxiliary repair stations to overcome casualties. There were not thousands of labourers ready to coal the ships. There were no peaceful harbours to anchor in during the fury of the gale, or when great repairs were needed. There was a vigilant and aggressive fleet for our enemy to watch, and the defence fleet had at its command within a few hours the resources of the best machine shops in the world. As the battle of the Chatham had been a contest of machines, it was not surprising that we won. Their engineers and firemen—and there were none better afloat—had simply been used up by the fewness of numbers, the inexperience of many of the firemen, and by excessive work before the battle began. That mighty nation then looked for the cause of the collapse in the motive department of their vessels of war. It was found in a vicious organisation, which had not done justice to the engineer and his force of men. Then a structure fell, whose foundation stones were tradition and conservatism; and ever since in that service the purple stripe between the bands of gold has received the recognition it justly deserves. This battle also aroused our Government to the importance of the engineer force on board ship. Countless facts were then forthcoming of the vital necessity of the naval engineers' work being extended. It was then realised that on the engineers primarily rests the fighting efficiency of every navy. A reorganisation was effected. The superannuated officers of a previous generation, who had been indifferent to the development of machinery in vessels of war, regarded the whole reconstruction as revolution."

POWDERED COAL FIRING.

MESSRS. BRYAN DONKIN AND COMPANY, Bermondsey, London, S.E., are now experimenting with the Wegener system of firing. Small sacks of powdered coal, weighing about half a hundredweight are put into a conical hopper. The powdered coal gradually falls out of the sacks, as required into the hopper, and then on to a sieve about 5½in. diameter, with small openings in it. The powdered coal would not go through this sieve with certainty without continual tapping, and this is done in the following way:—Immediately beneath the hopper, and level with the boiler-house floor, is an air pipe about 20in. diameter, through which nearly all the air for combustion enters. As it enters it is made to pass through the blades of an air-wheel or turbine, and this passage of the air causes the latter to revolve like a smoke-jack. On the axis of this air-wheel there is a little knocker which taps the sieve about 150 or 250 times per minute, causing the powdered coal to descend vertically through the sieve, meeting the air for combustion as it ascends vertically. The powdered coal and air for proper combustion in this way get mixed thoroughly together and pass on into the boiler flue, each particle of coal being surrounded by air. There is no grate and there are no fire doors, and the stoking simply consists of putting a sack of powdered coal from time to time into the top of the hopper and seeing that the right amount of air is going in for combustion. If there is not sufficient air for proper combustion entering through the main opening, as seen by a little smoke, there are two other smaller pipes where additional air can be admitted, each kind of coal requiring a somewhat different amount of air. The only object of the air-wheel revolving, from 50 to 80 revolutions per minute, is to shake the sieve and cause the powdered fuel to go into the furnace in the quantity desired. When more steam and coal are required a greater knock is given to the sieve and more powdered coal is burnt; when less is required a less shake is necessary. A screw adjustment for knocking is provided to regulate the amount of coal entering, which is done by turning with two fingers a half-inch thumb-screw. The only duty of the attendant is to put the sacks of coal into the hopper, and he ascends a short ladder to do this. He also has to regulate the amount of air for combustion, and then there is no smoke. He can therefore attend to several boilers. An alalysis of gases of combustion proves that the combustion is excellent and the amount CO_2 is much higher than with ordinary furnaces.

A GOOD BEARING.—We have received some particulars of an excellent bearing, which deserve publicity. The bearing in question was made by the Phosphor Bronze Company, of Southwark-street. It is a footstep loaded to about 480 lb. on the square inch. It is in use at Messrs. Fry's chocolate and cocoa manufactory, Union-street, Bristol. The upright shaft which rests upon it is 8in. diameter at the bottom end, and together with wheels, &c., fixed to it, weighs between 10 and 11 tons. The revolutions are 65 per minute. During the first two years the bearing was very free from excessive heat, and the wear has been almost imperceptible. Messrs. Fry state that the cost of lubricating the bearing with castor oil is something less than 2d. per week. The footstep was put into use in 1879. The shaft was recently lifted and found in excellent condition. The wear of the footstep was $\frac{1}{32}$in. after sixteen years' work. We shall be glad to publish similar results obtained with other bearings and lubricants if our correspondents can supply particulars. The loads must not be overlooked, however; any material, indeed, will do for a light load.

AUSTRALIAN NOTES.

PRIVATE Bills are now before Parliament for a connection across Sydney Harbour, one for powers to build a high-level bridge, and another for a subaqueous tunnel. From time to time various schemes have been suggested, and the Government strongly urged to provide a better means than water transit for the enormous traffic—both passenger and vehicular—that travel daily between Sydney and North Sydney; but the matter has always been shelved on the question of cost. The only means of conveyance at present is in the hands of one private company, whose monopoly allows it to easily declare an annual dividend of 10 per cent.

It is reported that Mr. J. H. Smith, whose term of office as chairman of the South Australian railways recently expired, has been offered the management of the Cape railways at a salary of £2500 per annum.

The annual report of the Department of Mines and Agriculture, New South Wales, for the year 1894, gives some interesting information, although the report is very late before such information is available. During the year 766 applications to lease Crown lands for mining purposes were dealt with; 586 were for gold-mining leases, comprising an area of 2819 acres, and 180 were for mineral leases, embracing an area of 10,427 acres. The reduction of 633 acres of auriferous land and 4200 acres of mineral land, as compared with that applied for in the previous year, is accounted for as owing to the general depression which has restricted the investment of capital in mining ventures, and to the low price of some of the metals. The total area of Crown lands held under lease in the Colony was 64,975 acres for the year.

The result of the operations effected from the aid of the "Prospecting" vote is regarded as satisfactory, by which means several discoveries are made and mines opened up that would otherwise be abandoned, owing to want of funds. Out of 1068 applications, aid was granted in 397 cases.

One of the best solutions to relieve the unemployed was the suggestion made some time ago by Mr. Harrie Wood, Under-Secretary for Mines, to the effect that free railway passes and a miner's right on credit be granted to the men to enable them to proceed to some of the gold fields of the Colony, where the men thought they would be able to earn a living by "fossicking." This has not only been the means of relieving a large body of men, but has made a decided increase in the quantity and value of gold won in the Colony.

The number of applications received by the Superintendent of the Government Labour Bureau was 9572 during the year.

The aggregate value of the mineral product of the Colony to the end of 1894 amounted to £109,336,847.

The output of coal shows an increase of 393,748 tons to that of the previous year; but with a decrease in value of £16,149, due to the very low price prevailing. The average price of coal for the year, viz., 6s. 5·53d. per ton, is the lowest since the year 1849.

The number of men employed in and about the collieries, raising coal and shale, was 9428.

The approximate number of miners engaged in gold mining is estimated as follows:—Alluvial miners, Europeans, 7982; ditto, Chinese, 760; quartz miners, Europeans, 8465; total, 17,207. The approximate number of men employed for minerals, other than above, is estimated at 6273.

The progress and development of the railways in West Australia is a good index of the prosperity of that colony. The Engineer-in-chief and Acting-General Manager for Railways has furnished a report on the working of the railways for the past four years, bringing the information up to the 30th June last. Owing to a variety of causes, published statements of the working have not been issued for a considerable period, and the information now published will be read with exceptional interest. The return on capital invested for the year ending 30th June last is—with the probable exception of some Indian lines—the highest of any State railway in the world. In the year 1891, the net earnings, after paying working expenses, were only £498, while for the year ending June 30th, 1895, the gross revenue not only met working expenses and total interest on loan expenditure, but also left a surplus of £30,838.

During the year the following lines were opened for traffic:—Northam to Yilgarn, 170 miles; Mullewa Junction to Mullewa, 57 miles; Boyanup to Busselton, 27 miles; making a total mileage of 573.

In addition to the fact of efficient management, two factors are to be taken into consideration in the remarkable results achieved—being the abnormally low cost of construction, the average being only £3804 per mile—and the opening up of the goldfields, causing a great rush of traffic.

The Acting General Manager states, "At the inauguration of responsible government in 1891, an important reason for the non-productiveness of the railways was traced to the existence of the very steep grades on the Eastern Railway, in conjunction with light rails, and, consequently, light locomotives, whereby reasonably heavy trains could not be hauled, and in order to as quickly as possible in some measure attain better results, heavier rails—60 lb. in place of 46 lb. to the yard—were decided to be laid down, and more powerful locomotives obtained. These improvements having, therefore, now been in existence for a considerable time, it is natural to look for some evidence of their effect towards reducing the working expenses—especially of the locomotive branch of the service." The locomotive expenses on the Eastern Railway, as compared with the gross receipts, have been reduced from 62·42 per cent. in 1890, to 27·91 in 1894-5.

Since 1891, £127,438 has been expended in the purchase of additional rolling stock for the use of lines open.

Various improvements have been made in the type of locomotives and rolling stock, thereby reducing the working expenses.

The statistical returns furnished along with the report are very comprehensive, and supply a long-felt want in making comparisons of the Australian colonies.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THIS has been the week of the January quarterly meetings, the gatherings being held as usual in Wolverhampton yesterday, and in Birmingham to-day — Thursday. But for the unfortunate developments of the last ten days or a fortnight in foreign affairs we might have had a good trade. As matters now stand, however, trade was very much interfered with, and buyers hesitated a good deal about operating. Marked bars were re-declared at the former figure of £7 per ton. Messrs. John Bradley and Co. re-quoted their best bars at £8 per ton, or £1 10s. in advance of any other firm. Their second quality bars were £7 10s. The firm profess that if they were to reduce prices they should have to also reduce quality, and rather than do this they prefer to occupy an independent and exceptional position. The Earl of Dudley's quotation for bars was £7 12s. 6d as a basis. Messrs. Noah Hingley and Sons quoted their prices for the new quarter as follows:—"Lion" bars, ordinary, £7; best, £8 10s.; double best, £9 10s.; and treble best, £10 10s. "Lion" turning bars are £8; rivet iron, £7 to £8 10s. and £9 10s., according to quality; and chain iron, £7 to £8 10s. and on to £10 10s. Messrs. William Barrows and Sons quoted bars, £7; hoops, £7 10s.; and cast chain iron £8 10s.

The Unmarked Bar Association upheld the combination formed just twelve months back. It was at the January meetings of 1895 that the association was first organised. The association started with a membership of sixteen firms, and the minimum was fixed at £5 5s. at works, or £5 7s. 6d. delivered. This—Thursday—afternoon the association was as strong as ever, and the basis price for the new quarter was declared at £5 15s. per ton, makers' works, showing an advance on the twelve months of 10s. per ton. It was announced that most of the forty or fifty common bar firms established in the district were now members of the association, and all the members express themselves strongly opposed to any attempt to reduce prices. Merchant bars on the open market were mostly £6 to £6 10s.

The makers of sheets for consumption by the galvanisers reported themselves still in receipt of a good demand, though it was admitted that orders are less plentiful than a month ago. Confidence is, however, expressed that the demand will again early resume its old proportions if political troubles can be got out of the way. Prices were quoted at £7 2s. 6d. to £7 5s. for doubles; £8 for lattens; and £7 for singles. Galvanised corrugated sheets were quoted £10 7s. 6d. to £10 10s., 24 gauge, f.o.b., common sorts. At the January quarterly meetings last year sheets for galvanising and similar purposes were quoted £6 5s. to £6 7s. 6d. for doubles, and £7 for lattens. Galvanised sheets were £9 7s. 6d. to £9 10s., and £9 12s. 6d. as the minimum for qualities of 24 w.g., bnndled f.o.b. Liverpool. The only doubt in the present state of the sheet iron trade is occasioned by the knowledge of the additional new mills which have recently been re-started. It is not, however, to be assumed that all the mills existing at old works which have recently been re-acquired will immediately be brought into activity again; hence the market is somewhat reassured. Especially does this apply to the Woodford Ironworks, Smethwick, now in the occupation of Messrs. Ash and Lacy, which comprise in all seven mills, and to the Gospel Oak Ironworks, Tipton, which have been acquired by Messrs. Page and Wilkinson, jun., and where some five or more mills are erected.

The advance declared last quarter-day of £2 per ton on large tinned sheets, and £1 per ton on stamping sheets, was upheld to-day by the best—thin—sheet firms, and Messrs. Knight and Crowther quoted coke tinned sheets, singles, £25, and charcoal ditto £27; while Stephen Thompson and Co. quoted tinned sheets £24 singles, and £25 10s. doubles. Black sheets, singles, are quoted by Knight and Crowther £9 for the Dibdale brand, £10 K.B.C. brand, £11 10s. Knight's crown, and £13 Knight's plough. Demand in the pig iron trade was slow, and prices easier. All descriptions of pig metal were three months ago in large call, and makers were very strong, many of them having closed their books. Northampton forge pigs last October were a minimum of 41s. to 42s. 6d.; Derbyshires, 42s. to 43s., less 2½ per cent.; and Lincolns, 44s. to 44s. 6d. net. Local all-mine hot-air pigs were advanced 2s. 6d., making the price 57s. 6d., while cold-air pigs were 87s. 6d. This afternoon Derbyshire and Northampton pigs were easily procurable at 41s. 6d. to 42s. 6d. in actual business, although higher prices were quoted nominally, and Lincolns were also rather easier. Staffordshire cinder pigs were 36s. to 37s. 6d., and North Staffordshire part-mines at 44s. Steel occupies a good position, and prices are well sustained, particularly for constructional and other engineering descriptions.

Satisfaction is occasioned this week by the character of the Board of Trade returns for the month of December and the completed year. Our iron and steel exports during the month amounted in all to 220,579 tons, and their estimated value was £1,774,497. These returns show an improvement of 10 per cent. in quantity and 13 per cent. in value on the corresponding month of last year. For the whole twelve months of 1895 our exports under this heading improved in quantity by a little over 7 per cent., and in value by a little over 5 per cent. They amounted to 2,838,149 tons, compared with 2,649,998 tons in 1894, and 2,856,574 tons in 1893. The corresponding values were in 1895, £19,695,382; in 1894, £18,688,763; and in 1893, £20,592,577. It will thus be seen that the year just closed marks an improvement on its predecessor, but has failed by a rather substantial margin to reach the figures of two years ago. The following are the increases in particular items on the year's trade:—Pig and puddled iron, 8 per cent.; bar, angle, &c., 3 per cent.; railroad material, a fraction; wire, 14 per cent.; cast and wrought iron, 9 per cent.; old iron, 12 per cent.; galvanised sheets, 15 per cent. The articles showing a decrease for the twelve months are:—Telegraphic wire, 43 per cent.; hoops, sheets, &c., 26 per cent.; unwrought steel, 1 per cent.; tin-plates, 2 per cent.; and unwrought tin, 11 per cent. The machinery exports for December were of the value of £1,099,088 against £839,359 in December of last year, showing an improvement of £259,729. For the twelve months the machinery exports were worth £12,428,143, against £11,140,112 in 1894, or the very satisfactory increase of £1,288,031. Steam engines figure this December at £222,850, against £239,939 in the closing month of last year. For the twelve months the figures are: 1895, £2,786,967; 1894, £3,065 103.

It is rumoured this week that the Birmingham Mint, Ltd., have just secured important contracts from the Russian Government for silver and bronze coins. It is stated that the contract will give full employment for upwards of six months. The firm are already engaged on other European orders for coins, and are also well employed in their various metal branches.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The opening of the year has so far been anything but encouraging, but notwithstanding increasing complications abroad, and the threatened further protraction of the dispute in the shipbuilding trade, there is still a very general feeling of confidence in the future, whilst the remarkably steady tone maintained in the market is satisfactory evidence of the sound, healthy condition of trade. The position is naturally not so strong as it was; the uncertainty of the outlook necessarily checks forward buying, and users who have orders to place hold back as much as possible for the chance of lower prices, but as far as the principal brands of iron both raw and manufactured, used in this district, are concerned, makers have not so far given way to any appreciable extent. Where there has been any actual breakdown in prices it has been in some of the purely speculative brands, or with iron in second hands, which has been pushed upon the market by a few nervous holders; and considering the present disturbed situation, the continued generally strong position that is maintained is a most hopeful feature in the market.

There was about a full average attendance on the Manchester Iron Exchange on Tuesday, but only a very slow business doing generally. Pig iron met with but very little inquiry, and for the most part business was only practicable at some concession upon recent quotations. Local and district makers are, however, so well sold for the present that they are under no necessity to seek for new business at lower prices, and although there has been practically nothing doing to really test the market, their quotations may be said to remain unchanged on the basis of 46s., less 2½, for No. 3 foundry Lancashire; 46s. 6d. to 47s. 6d. for No. 3 foundry Derbyshire; and 41s. 6d. for forge to 43s. 6d. for foundry Lincolnshire, net cash, delivered Manchester. With regard to outside brands coming into this market, Middlesbrough is easier, and generally there is a good deal of underselling with second-hand parcels. Delivered equal to Manchester, ordinary foundry Middlesbrough could be bought at about 44s. 10d. net cash, with special brands quoted about 1s. per ton above this figure. For the leading brands of Scotch iron, however, quoted rates scarcely show any very appreciable giving way, 47s. net cash, delivered Lancashire ports, being about the average for Eglinton, with 48s. 6d. asked for Glengarnock.

Finished iron makers report new business coming forward only in very limited quantity, but so far as bars and sheets are concerned, they are well booked over the next two or three months and steady at late rates, except that some Staffordshire bars might be bought for prompt delivery at 2s. 6d. to 5s. per ton under recent full quotations. The general quoted prices remain, however, at £5 10s. as the minimum for Lancashire bars, with Staffordshire makers still quoting £5 15s., and sheets £7 10s. to £7 12s. 6d., delivered here. Hoops are exceedingly quiet, mills not having sufficient work to keep them going half time, but the Association list rates remain unchanged at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, and 2s. 6d. less for shipment.

The position in the steel trade remains unsatisfactory, ordinary foundry hematite being in but very slow request, and not averaging more than 55s. 6d. less 2½d., with steel boiler plates obtainable from £6 to £6 5s. per ton, delivered Manchester district.

In the metal market the recent giving way in raw material has been followed by a reduction of ¼d. per lb. upon all descriptions of manufactured goods except yellow metal plates, and for delivery Manchester district list rates are now as under:—Solid drawn brass boiler tubes, 6d.; solid drawn brass surface condenser tubes, 7½d.; solid drawn copper tubes, 7¼d.; brazed copper gas and steam tube, 7d.; brazed brass gas tube, 6d.; brass wire, 5¼d.; copper wire, 6½d.; and rolled brass, 5d. per lb,

The position throughout the engineering industries continues generally satisfactory, establishments for the most part resuming operations after the holidays with a fair weight of orders in hand, sufficient in some branches to keep them well engaged over a considerable portion of the ensuing year. Of course, the disturbed outlook abroad has some effect upon the immediate prospects of the future, but not, so far as I can gather, to any really serious extent, and as an illustration I may mention that even the South African troubles have not checked the placing of orders in this district, one of the leading pump makers having in the last few days booked several separate orders for about a dozen different kinds of pumps, to be sent out to the Transvaal.

Reviewing the position of the Lancashire engineering industries throughout the twelve months just closed, it is satisfactory to note a generally decided improvement as compared with the last three or four years. Although 1895 opened with much the same discouraging outlook that characterised the iron and coal trades of the district, engineering works in nearly all departments being short of orders, and the unemployed list of the trade union societies considerably above the average, prospects began to brighten early on in the year, and an improvement set in which has been well maintained. This improvement, however, did not make itself felt in any very special measure during the first three months, and probably not to the same extent in the Manchester district as in other important engineering centres. The Amalgamated Society of Engineers, which commenced the year with an out-of-work list of from 9 to 10 per cent. of the local membership, did not materially improve upon this unsatisfactory state of affairs until well into the second half of the year, but the Steam Engine Makers' Society was able to record a fairly substantial reduction in the number of out-of-work members, which at the commencement of the year stood at about 5½ per cent., and during the first three months got down to about 4 per cent.

During the first quarter foreign orders of considerable weight were secured by some of the leading firms, whilst there was also a fair amount of new work stirring in connection with railway requirements, and from the commencement of April onwards, the position steadily improved, with only occasional temporary slight fluctuations, all through the remainder of the year. Amongst stationary engine builders a large weight of new work was given out, the principal portion of which was for abroad, in connection with extensive orders for cotton machinery for shipment, and machine tool makers also secured a good deal of new work. This increasing activity was necessarily reflected in the lessened unemployed lists of the trades union societies, the returns of the Amalgamated Society of Engineers in June showing not more than 7½ per cent., and those of the Steam Engine Maker's Society 3 per cent. of the local membership in receipt of unemployed benefit. A still more marked improvement was manifested during the second half of the year, all branches of industry getting busier, cotton machinists booking considerable orders for China and Japan, whilst the shops of both light and heavy stationary engine builders were filled with work for some time ahead, and the out-of-work returns of the trades union societies showed a further substantial reduction, until the Amalgamated Society of Engineers had not more than 5 per cent. and the Steam Engine Maker's Society only about 2½ per cent. of the local membership in receipt of donation benefit.

Towards the end of the year some slackening off in new inquiries became here and there noticeable, the protracted dispute in the shipbuilding industries having no doubt indirectly a depressing tendency. Generally, however, the year closed with the leading engineering industries throughout Lancashire in a sound, healthy position, and mostly well supplied with work, some branches having orders on their books to carry them well over this year. This is especially the case in the stationary engine building trades, both as regards light and heavy departments. Locomotive and railway carriage and wagon builders, who have been but very indifferently off for orders for the last two or three years, have booked a considerable weight of new work, which in some cases will afford pretty full employment over the next six or even twelve months, and there are prospects that the next few months will bring forward a still further important accession of new work. Machine tool makers have opened the year generally well supplied with orders, and most of the cotton machinists are booked for a considerable time ahead.

The boilermaking trade, of which Manchester is perhaps the most important centre in the kingdom, has shown a good deal of fluctuation, but generally establishments have been kept tolerably well engaged; and in general engineering of a constructive character there has been a fair amount of work stirring. The previous protracted period of depression had, of course, so depleted the order books of engineers that, when the improvement set in, the eagerness to secure work prevented any appreciably better prices being obtained, but with engineering establishments now, with comparatively few exceptions, well supplied with orders, a more independent position of affairs has been established, and improvement in the matter of prices is beginning to make itself felt. The trade union organisations closed the year, as regards the employment of their members, in a better position than has been known since 1891, and as compared with 1894, they have scarcely half the number of members on their books in receipt of out-of-work support that they had at the same period of that year.

With regard to shipbuilding, the decline of this branch of industry, so far at least as the Liverpool side of the Mersey is concerned, to which I referred in reviewing the course of trade during 1894, has continued in 1895; but on the Birkenhead side there has been a decided revival of activity, and a greater weight of new work has been secured than for a considerable number of years past. Messrs. Laird Brothers have during the year completed the following vessels:—Salvador Correa, steel screw steamship of 240 tons gross register, 480-horse power, for foreign owners; Queen of the North, steel paddle steamer, 600 tons, 1700-horse power, for British owners; a steel paddle steamer, 111 tons, and 50-horse power, for foreign owners; The Quail, Sparrowhawk, Thrasher, and Virago, twin screw torpedo destroyers, each 320 tons, and 6000 indicated horse-power, for H.M. Navy. The Great Western Railway Company's steamer Pembroke has been converted from paddle to twin screw, with new engines and boilers of 3300-horse power.

In addition to the above work, Messrs. Laird have in hand important home and foreign Government orders for war vessels of various descriptions, including the battleship Mars, which will probably be floated in March, when there are spring tides suitable for the undertaking. This vessel is making rapid progress, and would have been completed sooner but for considerable delay in the delivery of the armour plates. She will be similar to the Magnificent and Majestic, just commissioned, the orders for which were, however, put in hand several months before that for the Mars was placed. The firm has also in hand other important work, including a new lot of 30-knot torpedo destroyers, upon the first of which they expect to have steam very shortly, and four mail steamers for the Holyhead service, the first of which is now plated, and the second one in frame.

On the Liverpool side of the Mersey the shipbuilding industry has practically resolved itself into building small vessels, tugs, barges, &c., and of this kind of work, with repairs, re-boilerings, and conversions, there has been a fair amount. Messrs. John Jones and Sons have built two steel caissons, of a tonnage of 1500, and sixteen small steamers and barges for foreign owners, two being twin-screw, ten sailers, three paddles, and one single-screw, with tonnages of from 450 downwards. Messrs. Clover, Clayton, and Co. have built nothing, with repair work below the average. Messrs. D. Rollo and Sons have re-boilered a number of steamers and done some heavy repair work, whilst they have in hand some small sets of engines, boilers, &c.; and Messrs. H. and C. Grayson have dry-docked about 300 vessels, steam and sail, of all tonnages, and done a considerable amount of repair work to large vessels. Messrs. James Harland and Co. have turned out only one new vessel, the Merlin, a wooden screw steamer of 260 tons, for carrying limestone; and Messrs. James Royden and Co., and Messrs. Gilchrist and Co. have built no vessels, although the last-named firm has in hand three light draught steel screw steamers, to be completed during the present month. The shipbuilding dispute on the Clyde and at Belfast has temporarily interfered with the completion of some of the orders which Liverpool marine engineers have in hand, but of course as soon as the dispute is settled these orders will go on.

The opening of the year has not brought forward any improvement in the coal trade, and although in most cases the holidays at the pits have extended over a longer period than usual, supplies are plentiful, and prices not more than maintained at late rates. The better qualities suitable for house-fire purposes move off only moderately, with quotations unchanged. In the lower descriptions supplies continue largely in excess of requirements for iron making, steam, and general manufacturing purposes, and the competition to clear off surplus output causes excessive cutting in prices, which remain quite as low as at any time during the past twelve months. For inland sales good qualities of steam and forge coals scarcely fetch more than 6s. to 6s. 6d., whilst for shipping orders 5s. 6d. per ton at the pit mouth is being readily taken. The present somewhat restricted output of engine fuel is moving off readily, and prices are steady at late rates, averaging 3s. to 3s. 6d. for common, to 4s. 6d. and 5s. for best qualities of slack at the pit mouth.

Barrow.—There is less life in the hematite trade, and the revival which was expected has not set in. The reason for this to a great extent is to be found in the fact that the engineers' strike is crippling trade and checking the need of deliveries. The complicated state of our foreign relations has also much to do with the depression in the iron market. Prices are at easier rates, but are firm, with warrants at 46s. 4d. net cash sellers, and buyers at 46s. 3½d. The quotation for makers' iron is nominally given at 48s. Stocks have increased this week 4945 tons, and now stand at 298,436 tons. Thirty-six furnaces are in blast, compared with thirty-one in the corresponding week of last year.

Sales of iron ore are few, and the market is flat. Ordinary sorts are at 10s. per ton net at mines. Further supplies of Spanish ore are to hand this week.

The steel trade is brisk in rails, and makers are not only busy, but are well sold forward. Heavy sections are at £4 15s. The plate trade is quiet, because shipbuilders are not in a position to give out specifications owing to the engineers' dispute. Tin bars are also quiet, but billets, blooms, and heavy castings are in demand.

The shipbuilding and engineering trades are very busy, chiefly on Admiralty work, and other orders are expected. The fitting up of H.M.S. Powerful is making much progress, and it is expected she will be ready for delivery soon after midsummer.

The coal and coke trades show a little more life. The demand is improving, and prices are stiffening.

Shipping returns show an improvement. The exports of metal from West Coast ports show during the past week 4726 tons of pig iron and 10,220 tons of steel, compared with 2185 tons of pig iron and 2667 tons of steel in the corresponding week of last year, an increase of 2541 tons of pig iron and 7553 tons of steel. The aggregate shipments of pig iron this year so far have been 7131 tons, and of steel 18,527 tons, compared with 2965 tons of pig iron and 8673 tons of steel in the corresponding period of last year, an increase of 4166 tons of pig iron and 9854 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

DURING the first week in the New Year the pits have been fairly well employed, although the expectation of a large demand, should frosty weather ensue, has not been realised up to now. The settlement of a dispute at a local colliery—Hickleton Main—saw 1895 out without a single strike, with the exception of a slight difference at a South Yorkshire pit. This danger has now happily been averted, and the beginning of 1896 has not so many industrial clouds as the opening of 1895. The demand for household coal is very poor. After the holidays terminated a better tonnage was forwarded to the metropolis and the southern markets generally, although sales of Yorkshire coal are extremely slow, and are made increasingly so by the keen competition of seaborne coal, which has the effect of lessening values in spite of the attempts to keep them up. The business done by coast in this quality of coal is only moderate, and the demand all round is far from active. Quotations remain very much the same as when last reported, with little trade transacted at high rates, while secondary qualities can be purchased at about the same price as ruled during the midsummer of 1895. Silkstone best is at 8s. 6d. to 9s. 6d., with ordinary from 7s. 6d. per ton. Barnsley house can be purchased at 7s. 6d. to 8s. 6d., with secondary sorts at 6s. 9d. per ton. Flockton sells at 6s. 9d. to 7s. 9d. per ton, while thin seam coal is as low as 6s. 3d. per ton.

Steam coal is in fairly good request, considering the season of the year. The Humber ports are naturally taking but a poor tonnage at this time, although a few of the collieries are forwarding a large amount. Railway companies are requiring a full average on contract account, with the additional advantage that the improved condition of the iron and steel trades induces a better request. Prices are extremely unsatisfactory, and supplies can be obtained at very low rates. Barnsley hards, 6s. 6d. to 7s. 3d., with secondary qualities at 6s. 6d. per ton. Gas coal is in better request, and collieries working this class of fuel are fully employed. The bulk of the business is on contract account, and at from 6s. to 7s. per ton. Manufacturing fuel is steadier, with prices low, and stocks accumulating at some of the collieries. Small nuts are at 5s. to 6s. per ton; screened slack, 2s. 9d. to 3s. 9d.; with pit slack, 2s. 3d.; smudge, 1s. Coke is reported better at 8s. to 10s. per ton.

The cheerful anticipations of the latter half of 1895, that a very good year could be looked for in 1896, have been somewhat dashed by the serious political troubles in America and other places. These have weakened confidence and shaken the calculations of business men. There is every hope, however, that the horizon will be cleared, and that 1896 will, after all, prove to be one of the most successful years there has been for some time.

At the beginning of each year there is always a good deal of work left over to be completed, and this has been especially the case in the present year. The armour plate mills and forging presses are extremely well engaged on Government account, with every prospect of large orders from Japan, China, and other foreign countries, as well as further requirements from the Home Government. Makers of engines, carriages, wagons, tires, axles, buffers, and all the necessary parts of railway plant generally, are very well off for work, and next week will be once more in full swing. The Christmas holidays have been considerably curtailed this season, owing to all the departments being full up with orders. Better prospects have to be reported in the engineering trades as well. The opinion generally expressed in this district is that business will continue to improve. The requirements at present placed will keep manufacturers very busy well into 1896. Both Bessemer and Siemens steel are in large demand, and a similar remark may be applied to common and forge iron. The rolling mills started this week, and owners report a sufficient quantity of orders in hand to keep them well employed for some months yet.

In the lighter trades the expectations of a better business are as sanguine as in the heavy industries. Cutlery and plated goods are largely called for, and the same may be reported of ornaments and more costly silver goods. Skate makers do not take quite such a cheerful view, and hardly expect to clear their heavy stocks this season. Many of them, however, anticipate a return of the extraordinary frost of 1895, and if this prove the case, they have still time to dispose of their stocks. Scythe, sickle, machine knives, reaper sections, and other goods are in excellent request for early delivery.

Through the courtesy of the United States Consul at Sheffield—the Hon. B. R. Bedle—we are now able to compare the business done with America in cutlery and steel during last year with 1894. For the quarter ending December 31st, cutlery was sent to the value of £45,483 2s. 9½d., which is a decrease as compared with £49,502 14s. 10d. for the same period of 1894. In steel, however, a large increase is shown. The amount reached was £96,601 12s. 1d. last year, as against £69,670 5s. 8d. in 1894. For the quarter the total amount of exports was £158,755 4s. 6d., and in the corresponding period of 1894 £146,970 10s. 5½d., or an increase of £1784 14s. For the year just closed, the total value in both cutlery and steel sent to the States was £536,243 13s. 9d., as against £386,344 18s. 0½d., or an increase of £149,000.

Our foreign trade in hardware and cutlery for the twelve months amounted to £1,862,858, which is £28,000 better than for the previous year. Taking the month of December, the value was £165,689, as compared with £141,186; so that it will be seen that the improvement in business was distinctly accentuated during the closing period of the year. In steel, unwrought, there was also an advance, the value exported last month having been £183,724, against £171,966 for the corresponding month of 1894.

Sheffield is an important centre of limited liability companies, especially those affecting coal, iron, steel, and allied industries. A tabulated list of leading concerns reflects the significant improvement in trade which has taken place during the year, particularly in the latter half of it. In fifty-three companies, the shares of which are largely held in Sheffield, the called-up capital is £15,378,101, and the market price, as per Stock Exchange quotation, is £13,970,457. This shows a net depreciation of £1,407,644. Several companies have improved their general position very materially, noteworthy amongst these being Vickers, Sons, and Co., who now show an increase of £496,875, against a decrease last year of £9375. The Yorkshire Engine Company has also improved, its capital showing an appreciation over the paid-up amount of £8000. In 1894 the net depreciation in these companies was £2,667,436, and as that was reduced last year to £1,407,644, the improvement in the position of the companies in the Sheffield district is increasingly manifest. There is every expectation locally that this change for the better will be accentuated during the present year.

It was stated some time ago that the steel works at Maryport had been purchased by Mr. James Duffield, manager for Messrs. Charles Cammell and Co., at their Derwent Iron and Steel Works, Workington. These have now become the property of the company, and are to be used for the manufacture of finished steel. With that view the works at Maryport will be dismantled and the plant removed to Workington. It is stated locally that the negotiations for the purchase of the Solway Ironworks at Maryport by Cammell and Co. are almost completed, and that the furnaces will shortly be put in blast.

The Transvaal "surprise" has had some adverse effect on local business, weakening confidence and spreading distrust. Of course the orders from South Africa were on their way before the troubles began, and although none of these have been countermanded, so far as inquiries made to-day—January 8th—can disclose, it is expected that the result of the upheaval will be to stop the brisk call which had begun to set in from the South African markets.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE continuation of the Clyde-Belfast engineering dispute does not, in the presence of unsatisfactory Imperial influences, much affect the market, neither does the somewhat unfavourable annual stock returns which have been issued by the Scotch and Cleveland ironmasters, both of which Associations have to report for last year an excess of production over consumption, and increased stocks. The iron trade in the North of England have added 75,006 tons to the stocks of Cleveland iron alone, though they have added but 17,343 tons to the output, and from this it is apparent that the consumption was not as large last year as it was in 1894. No particulars of the stocks of hematite pig are issued by the Cleveland Ironmasters' Association, but there can be no doubt that they have been largely added to. Still the stock of Cleveland pig iron in the North of England—305,669 tons—is not an excessive one for the early days of a revival, and it is not half of what has been held, seeing that in August, 1886, no less than 728,094 tons were reported—that being the largest quantity ever stored—while the smallest was in August, 1892, when it was but 46,108 tons.

Lower prices have been taken this week for No. 3 Cleveland pig iron, and also for hematite pig iron; otherwise quotations are fairly-well maintained, as producers have good orders booked, the result of the activity of buyers in the last quarter, and they are in no hurry to agree to reduced prices. No. 3 Cleveland G.M.B. pig iron has been generally quoted at 36s. 6d. per ton for prompt f.o.b. delivery; but some business has been done by merchants at 36s. 3d. this week. Buying for forward delivery is practically at a standstill. Cleveland warrants have been weak during the last few days, and on Tuesday buyers would pay no more than 36s. 1½d. cash, for Cleveland warrants, their price on Wednesday being 36s. 2½d. The stock of Cleveland pig iron in Connal's warrant stores on the 8th inst. was 173,759 tons, or 2059 tons increase this month. No. 1 Cleveland pig iron is quoted 38s.: No. 4 foundry, 36s.; grey forge, 35s. 9d.; mottled, 35s. 3d.; and white, 35s. The scarcity of forge qualities is as great as ever. Some thought that over the holidays the blast furnaces would not work so well as usual, and that there would he a large proportion of forge in the output, but such does not appear to be the case, and it is very few firms who can supply any. Mixed numbers of East Coast hematite pig iron have declined in value, and while 45s. 6d. has been generally quoted this week, 45s. has in odd cases been accepted.

The December statistics issued by the Cleveland Ironmasters' Association were unsatisfactory, but the stocks did not show a larger increase than was expected. The production exceeded the consumption by 34,388 tons, makers adding 17,413 tons to their unsold stocks and 183 tons to their stores, while to the public warrant stores 16,792 tons were added. Still the makers have only about three weeks' production unsold, and the total stock is not over ten weeks' output. An increase in the production was reported of 16,359 tons, part of which may be accounted for by the extra day in December over November, and the total make was 261,469 tons, of which 127,148 tons was ordinary Cleveland. Palmer's Shipbuilding and Iron Company have blown in a furnace to make Cleveland iron, and the number now producing that is 49, while 45 produce hematite, &c., there being 94 furnaces at work, of which 72 are within the port of Middlesbrough. The Ironmasters' Association have deleted from their official list the names of three works which have been for years idle, and which it may be inferred will never work again, viz., the Norton, with three furnaces; the Seaham, with two; and the Ferryhill, with three. This leaves 133 built in the North of England, of which 98 are in the Cleveland district. The exports from the Tees were 24,741 tons less than in November, reaching only 55,229 tons, and the quantity for the year was 985,092 tons against 935,211 tons in 1894, and 914,083 tons in 1893.

The annual summary of make and stocks of pig iron in the North of England shows that the stock of Cleveland iron increased 75,006 tons, and that more iron was held than in any year since 1888. The total production was 46,980 tons less than in 1894, which showed the largest make in the history of the trade, but the 1895 return was the second best, the quantity being 2,916,439 tons. The output of hematite, &c., iron was 64,323 tons less than in 1894, but there was an increase of 17,343 tons in the make of Cleveland pig iron. Last year was the third in which the production of Cleveland iron fell short of that of other kinds.

Steel manufacturers are well-off for orders, and keep their mills in full operation, now that the holidays are over, but they find consumers very shy about distributing further orders. Finished iron makers, however, continue badly supplied with contracts, and there is nothing like full employment at some of the works. The Stockton Malleable Iron and Steel Company are erecting additional and larger mills at these works for plate rolling. Their works manager, Mr. Fred G. Mills, is leaving them to undertake an appointment at the Wishaw Works of the Glasgow Iron and Steel Company. He has been seven years with the Stockton Malleable Company. A tin-plate manufactory is to be started in a few days at Birtley. This will be the only one of its kind in the North of England, and the proprietors think there is no reason why tin-plates should not be made as cheaply in the North of England as they are in South Wales or Staffordshire, which monopolise the trade. Considerable quantities of iron and steel are sent from the North of England to Wales for tin-plate making.

Mr. William Henry Mascall, Bishop Auckland, assistant colliery manager under Messrs. Pease and Partners, has been appointed to the charge of the Joanroyd Colliery, Heckmondwike, and is succeeded by Mr. George Wall. The coalowners and others interested in the Blyth, Cramlington, and Hartley district, in Northumberland, have this week presented an address and casket to Mr. M. W. Ridley, son of the Home Secretary, on his attaining his majority.

Mr. R. Saxton White will join Mr. Henry F. Swan in the direction and management of the Walker Shipyard of Sir W. G. Armstrong, Mitchell, and Co. Mr. White filled the position of manager of this yard for several years before taking the management of the shipbuilding department of the Fairfield Shipbuilding and Engineering Company.

The coal trade is very dull, new orders being scarce in all branches, and especially is this felt in the house coal trade, which should be at its best at this time of the year, but actually is very slack now owing to the mild weather. The prices now taken for Northumberland steam coal are the worst that have ruled for the last seven years, and the ascertainment of average realised prices last quarter justifies the masters in claiming a further 2½ per cent. reduction of wages. In Durham the miners have by a large majority voted for the abolition of the Conciliation Board, 14,894 only voting for the continuance of the organisation, and 30,568 against, while 20,000 remained neutral. Mr. Charles Irwin, who has been twenty-one years with the company, has been appointed fitter and secretary to the Cramlington Coal Company, vice Mr. William Mason, who retires.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE issue of the annual statistics of the iron trade has been the most interesting event of the week. There is nothing of the nature of a surprise in the official figures. There has been a large increase in the production of pig iron, which has exceeded that of 1894 by no less than 441,298 tons, and is the largest make of pigs in Scotland since 1889. The consumption has also been large, but notwithstanding this there is a big addition to stocks, both in makers' yards, and in the public warrant stores. The following are the official figures made up by the Pig Iron Trade Association:—

	1895.	1894.	Increase.	Decrease.
Production as per makers' returns	1,096,912	655,614	441,298	—
Consumption—				
In foundries	126,661	125,516	1,145	—
In malleable and steel works	534,430	294,960	239,470	—
	661,091	420,476	240,615	—
Exports—				
Foreign	115,785	122,690	—	6,905
Coastwise	193,648	129,967	63,681	—
Rail to England	4,363	5,672	—	1,309
	313,796	258,329	55,467	—
Total consumption and exports	974,887	678,805	296,082	—
Stocks as on December 31st—				
Connal's stores	346,003	287,886	58,117	—
Makers' yards	134,621	70,713	63,908	—
	480,624	358,599	122,025	—

The average number of furnaces in blast during the year was 74 compared with 45 in the preceding year, and the average make per furnace was 285 tons per week, compared with 280 in 1894. The average price of G.M.B. warrants was 44s. 5d., against 42s. 8d. in the preceding year, the highest price being 49s. 1d. touched in September, and the lowest 41s. 0½d. in January.

The imports of West Coast hematites into Scotland were 88,500 tons against 141,000 in 1894, and the quantity brought in from the East Coast of England, chiefly from Middlesbrough, was 442,000 against 430,000 last year.

The exports of Scotch pig iron abroad were small, and it is apparent that these have been steadily decreasing, while the consumption of pig iron in Scotland is largely on the increase. The following is an approximate statement of the distribution of Scotch pig iron abroad in the last four years:—

	1895.	1894.	1893.	1892.
France	5,831	3,610	4,060	7,500
Germany, Austria, and Holland	21,479	19,556	37,546	47,287
Belgium, Denmark, Sweden, and Norway	6,449	7,786	7,212	11,143
Russia	9,629	6,565	7,470	11,955
Spain and Portugal	3,104	3,327	4,328	4,277
Italy	15,465	17,064	19,653	23,016
United States of America	3,008	1,672	4,615	14,144
British North America	5,456	6,080	14,057	22,913
Australia, East Indies, China, Japan, &c.	32,646	32,892	28,305	30,015

The business this week in the pig iron market has been limited, but prices are again reduced to the extent of about 3d. per ton, Scotch Cleveland and hematite all sharing in the decline.

The prices of Scotch makers' pig iron are as follows:—G.M.B., f.o.b., at Glasgow, Nos. 1, 46s. 6d.; Nos. 3, 45s.; Carnbroe, No. 1, 47s.; No. 3. 45s. 6d.; Clyde, No. 1, 50s.; No. 3. 47s.; Gartsherrie and Calder, Nos. 1, 50s. 6d.; Nos. 3, 47s. 6d.; Summerlee, No. 1, 51s.; No. 3, 47s. 6d.; Coltness, No. 1., 53s.; No. 3, 48s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 48s.; Carron, at Grangemouth, No. 1, 53s.; No. 3, 49s.

In the finished iron and steel departments business is quiet, and prices are practically unaltered.

Messrs. Neilson and Co., of Glasgow, have secured an order to construct 75 locomotive engines and tenders for the Midland Railway, and the other orders, in prospect or in hand, make the outlook in the locomotive engineering trade very encouraging.

The coal trade is quiet, the output being large, and prices as low as ever. The coal shipments in the past week were comparatively good.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

LAST week was the final one, in all likelihood, for holiday depression in the coal exports, and belief now is strong that the trade is now in for a vigorous period, unless colliers "sprag" the wheels, as they term it. Work is full on for January, and prices are ruling firmly, with upward tendency. The disquietude in military and naval circles has a tendency to strengthen this, and it may be anticipated that coaling stations will be well looked after. This week large shipments are noticeable from Cardiff, cargoes of 3000 tons numerous, and one of 4000 tons for Iquique, and one of 6000 tons for Bombay. Coalowners and shippers at Swansea have been gratified with an improved coal trade, in which cargoes for San Francisco figure well, and I am glad to note that a steady run has set in for Monmouthshire coal. On Saturday the Exchange report was to the effect that the demand was exceptionally strong.

It will be seen from quotations that figures are improving. On 'Change, Cardiff, mid-week, best steam coal was quoted at 10s. 3d. to 10s. 6d., and seconds were in good repute, best realising 10s., while inferior fetched 9s. 6d.; drys also sold well at 9s. to 9s. 3d.; best Monmouthshire, 8s. 9d.; seconds, 8s. to 8s. 3d.; best small, 5s. to 5s. 3d.; seconds, 4s. 3d. to 4s. 6d.; and drys, 3s. 6d. to 3s. 9d. House coal is in a very weak condition, and the opinion on 'Change is that if frosty weather should set in prices, instead of being simply firm, will go up. Latest Cardiff quotations are:—Best households, 10s. 9d. to 11s.; No. 3 Rhondda, 10s.; brush, 8s.; small, 6s. 6d. to 6s. 9d.; No. 2 Rhondda, 7s. 9d. to 8s.; through, 6s. 3d. to 6s. 6d.; small, 4s. 3d. to 4s. 6d. Swansea prices are:—Best steam, 9s. to 10s.; seconds, 8s. to 9s.; No. 3 Rhondda, 10s. to 10s. 6d.; anthracite, 8s. 9d. to 12s., according to quality; rubbly coke from 3s. 6d. to 3s. 9d., f.o.b., cash thirty days, less 2½.

Patent fuel is in better demand at Swansea. Last week the shipments totalled nearly 10,000 tons, prices 10s. 3d. to 10s. 6d., destination chiefly to France, Spain, Italy, Roumania, and Algeria. Cardiff prices 10s. to 10s. 6d., and a fair trade. Pitwood continues in steady request. Cardiff prices remain at 15s. 9d. to 16s. In coke, brisk sale is going on, both in furnace and foundry qualities. Latest Cardiff prices:—Furnace, 12s. to 14s.; foundry, 15s. 6d. to 16s. 6d.; special, 19s. 6d.

In the iron and steel trades as remarked on 'Change, Cardiff, this week, an easier condition is visible, and the chief features are a moderate demand for steel rails, but a falling one for the chief staple, tin-bar, due to discouraging signs in the tin-plate trade. In some cases I have noted large quantities of pig going into stock, and as showing successful rivalry, special cargoes as regards quantity coming into Newport, Mon., from Millom, Barrow, and Middlesbrough. These facts are grave comments on the agitation sought to be started against the iron and steel sliding scale. It is well known that it is only by rigid economy in wages, raw material, &c., that the Welsh ironmasters can compete with their rivals, and sometimes even this cannot be done. It is fortunate that quality is made to rank as of special importance, and this commands somewhat of a demand.

I heard lately that tin-platers are now so well versed in the character of tin bar, that they readily detect the source of the various brands, and are very rigid in keeping to those they have become accustomed to.

On 'Change, Swansea, mid-week, it was reported that prices, Glasgow pig, continued to fall, and that the reduction in price from last week amounted to 6d. Works are busy on rail contracts and other make, which will take some time to complete, by which time it is hoped others may be placed. Glasgow pig warrants were quoted at 44s. 11d.; Middlesbrough, No. 3, 36s. 1d.; hematite, 44s.; Welsh bars, £5 5s. to £5 7s. 6d.; steel sheets, £6 5s. to £6 10s.; steel rails, heavy sections, £4 10s. to £4 15s.; light, £4 15s. to £5 10s.; Bessemer steel bars, £3 17s. to £4; block tin, £58 10s. to £58 12s. 6d.; market for last-named is weaker.

In tin-plate prices remain unchanged. Shipments have been very quiet, and much below the usual quantity. Makers complain that they have gone through a very bad year, and that prospects are not opening out well. The December shipments from Swansea to the United States were nearly 5000 tons less than in December, 1894. A crisis may be expected by the action of the workmen's union in bringing operations to a standstill at the end of the month. This was expressed by a manifesto, issued by the secretary of the Tin Platers' Union of South Wales, directing them to hand in a month's notice. This has caused, said an authority this week on 'Change, "little or no excitement, for the trade has become unprecedentedly dull." The Old Lodge Works, Llanelly, are idle, but may start next week. At Port Talbot notices have not been given in. The Cwm Vale Works continue idle, but a new mill has been started at Margam. At Taibach Frwydwyllt men are working under weekly contracts. Glanwalie Works and Taibach are re-starting. In the Neath and Briton Ferry districts opinions differ. In the Neath district no notices have been issued. At the Melyn, where 200 men are employed, warehousemen and millmen could not agree, and matters remain in abeyance. At Briton Ferry the Gwalia men have received fourteen days' notice, and at the Villiers day-to-day work is the rule.

In the Monmouthshire district the tin workers of Blaina and Abertillery have been asked by their employers to grant a concession of 20 per cent, and the rejoinder of the Abertillery men was to offer 5 per cent., though it is really a matter of doubt with the proprietors whether a concession of 20 would suffice. Matters evidently, all over the tin-plate area, are in a peculiar state, but we must wait a week or two to see the drift of things. It is evident that, if no improvement sets in, a large number of mills will be permanently laid off. Last week the shipments of tin-plates only amounted to 37,397 boxes, and the quantity received from works was small—48,423 boxes. Present stocks at Swansea amount to 146,543 boxes. Swansea last week imported 483 tons of tin bars.

There is a good deal of ferment in some colliery districts. The Plymouth colliers, who are working under notice, have been holding meetings frequently this week, and so far the men appear bent upon resistance. I hope that wiser advice will prevail. The contention of the manager is, first, that the present rate of wages is in excess of that paid by the neighbouring coalowners; and, secondly, that unless a reduction be conceded, the collieries will not pay to work. Last year a considerable loss was sustained.

The Tyr Edmund Colliery has been stopped, and 150 men thrown out of employment. At a meeting of the Rhondda district of the Monmouthshire and South Wales Miners' Association, on Thursday, regret was expressed that the Bwllfa Proprietary would not concede arbitration.

A movement is on foot at Merthyr to erect a statue in honour of Sir W. T. Lewis, and in testimony to his eminent services to Wales.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

BUSINESS on the iron market has naturally been very quiet during the past week, but a hopeful, confident tone exists in all branches of the trade, and there has been sufficient work secured before the holidays to keep the establishments well engaged for a considerable time ahead.

From Silesia fair accounts are being received with regard to the position of the iron and steel industries, the majority of the works being in regular operation, while the prices quoted show firmness and here and there an upward inclination. Exports have been extremely poor of late, but there will be most likely a revival in February or March.

On the Austro-Hungarian iron market the business in pig iron is but small, but for malleable iron a comparatively good inquiry is reported to be coming in; especially the demand for all sorts of structural iron continues satisfactory, and fair prices are being realised. At the steel works a good activity is expected for the immediate future, as several large orders for railway and engineering requirements will shortly be given out.

No alteration has taken place on the French iron market, demand for most articles remaining quiet. Production is, in almost all departments, considerably higher than consumption, and stocks, consequently, show an increase. In Paris a slow business is done, both in raw and in finished iron, and dealers have in a number of cases been compelled to accept very low prices. Bars, for instance, only fetch 130f. p.t.. In the Department Nord a fair activity is maintained; one works has been fortunate in obtaining a pretty large order for Roumania.

The most limited business only has, naturally, been done on the Belgian iron market during this week and the last. Imports in pig iron have been very large during the last months, showing a considerable increase against previous years; in October, 1895, for instance, 20,000 tons were imported, against 4500 tons for the same month in 1894, and 7200 tons for October, 1893. During the first ten months in 1893 imports in pig iron were 100,000 tons, in 1894 they amounted to 175,000 tons, while in 1895 they rose on 185,000 tons.

In Rheinland-Westphalia the physiognomy of the iron trade continues favourable. At the blast-furnace works there have been plenty of orders booked to secure a good activity for the first quarter, and further contracts are expected to be placed in a week or two, which will reach far into the second quarter. There is only a moderate demand coming in for malleable iron just now, bars being particularly dull; girders, too, are a trifle more languid than before, and the Girder Convention has consequently resolved to desist from a rise in quotations for the present, M. 86 p.t. being considered as list quotations, free at works. Plates and sheets continue well inquired for on the whole. The steel works are likely to be in healthy occupation for some time ahead, the Essen Railway Administration having given out orders for railway material, which amount to several hundred tons.

The number of men employed in the iron industry of Germany and Luxemburg is statistically stated to have been:—

	Iron ore mines.	Blast furnaces.	Foundries, steel works.	Totals.
1873	39,491	28,129	116,254	183,874
1874	31,733	24,342	118,748	174,823
1875	28,138	22,760	114,003	164,901
1876	26,206	18,556	99,668	144,430
1877	25,570	18,188	95,400	139,158
1878	27,745	16,202	92,026	135,973
1879	30,192	17,386	96,956	144,534
1880	35,814	21,117	106,968	163,899
1881	36,891	21,387	114,433	172,711
1882	38,783	23,015	125,769	187,567
1883	30,658	23,515	129,452	192,625
1884	38,914	23,114	132,194	194,222
1885	36,072	22,768	130,755	189,595
1886	32,137	21,470	130,858	184,465
1887	32,969	21,432	130,176	192,577
1888	36,009	23,046	147,361	206,416
1889	37,762	23,985	161,344	223,091
1890	38,837	24,846	170,753	234,436
1891	35,390	24,773	170,268	230,431
1892	36,032	24,325	168,374	228,731
1893	34,845	24,201	169,838	228,884
1894	34,912	24,110	174,354	233,376

French foreign trade in iron and steel was, for 1894, as follows:—Iron ore, import, 1,638,439 t., against 1,630,441 t. in the year before; export, 247,027 t., against 301,731 t. in 1893. Pig iron, import, 54,599 t., against 82,351 t.; export, 117,803 t., against 104,485 t. Manganese iron, import, 4466 t., against 3598 t.; export, 40 t., against 64 t. Blooms, import, 249 t., against 765 t.; export, 325 t., against 225 t. Merchant bars, import, 12,019 t., against 10,525 t.; export, 12,606 t., against 12,021 t. Iron rails, import, 20 t., against 13 t.; export, 3214 t., against 1569 t. Angles, import, 899 t., against 460 t.; export, 1141 t., against 1085 t. Axles and tires in iron, import, 6 t., against 945 t.; export, 421 t., against 262 t. Hoops, import, 170 t., against 325 t.; export, 1295 t., against 2166 t. Plates in iron, import, 2966 t., against 2166 t.; export, 2302 t., against 2444 t. Tin sheets, import, 3698 t., against 3097 t.; export, 338 t., against 452 t. Wire in iron and steel, import, 683 t., against 1203 t.; export, 1277 t., against 1118 t. Billets and ingots, import, 2360 t., against 853 t.; export, 1542 t., against 111 t. Steel rails, import, 332 t., against 219 t.; export, 13,322 t., against 9017 t. Axles and tires in steel, import, 1350 t., against 2614 t.; export, 65 t., against 22 t. Steel plates and sheets, import, 1123 t., against 943 t.; export, 348 t., against 186 t. Steel wire, import, 298 t., against 265 t.; export, 13 t., against 20 t. Cast iron, raw, import, 5171 t., against 3631 t.; export, 10,072 t., against 8946 t. Cast iron, finished, import, 60 t., against 42 t.; export, 430 t., against 420 t. Cast iron, enamelled, import, 418 t., against 476 t., export, 401 t., against 347 t. Tools, import, 1599 t., against 1580 t.; export, 3552 t., against 3286 t. Wire net, import, 61t., against 40 t.; export, 210 t., against 181 t. Needles, import, 85 t., against 89 t.; export, 7 t., against 5 t. Fishing hooks, import, 12 t., against 17 t.; export, 30 t., against 22 t. Steel pens, import, 31 t., against 35 t.; export, 44 t., against 41 t. Cutlery, import, 28 t., against 25 t.; export, 555 t., against 518 t. Locks, &c., import, 151 t., against 153 t.; export, 2004 t., against 2014 t. Anchors, cables, chains, import, 628 t. against 600 t.; export, 1220 t., against 2331 t. Nails, import, 47 t., against 54 t.; export, 1570 t., against 1781 t. Horseshoe nails, import, 1697 t., against 2104 t.; export, 47 t., against 34 t. Wire nails, import, 21 t., against 20 t.; export, 1446 t., against 1436 t. Screws, bolts and nuts, &c., import, 270 t., against 207 t.; export, 2643 t., against 2884 t. Tubes, import, 1423 t., against 1774 t.; export, 666 t., against 791 t. Sundry small articles in iron or steel, import, 2066 t., against 1698 t.; export, 3627 t., against 3348 t. Enamelled hardware, import, 2540 t., against 2326 t.; export, 3081 t., against 3304 t. in the previous year.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THE attendance on 'Change to-day was not so large as is usually the case, owing to the general quarterly meeting taking place in Birmingham to-morrow. There was a vigorous tone in the steam and house coal markets. A good demand for pitwood prevailed at last week's prices. The coal shipments have not quite reached the large quantity of 70,000 tons sent away last week. The principal shippers, however, have heavy stems on, and doubtless large quantities of coal will be despatched from the port during the coming weeks. The following large steamers are included in the number of vessels expected shortly: Emin, Taragona, Marim, Donator, Les Beaulex, and Joseph Arbib.

An increase has taken place in the importation of iron ore. With other goods a large quantity of grain has been received. As predicted in our last week's report, a perceptible improvement has taken place in the ship repairing trade, nearly all the firms being well employed.

Prices ruling on 'Change to-day were as follows:—Coal, best steam, 8s. 6d. to 8s. 9d.; seconds, 8s. to 8s. 3d.; best house coal, 10s. 6d.; dock screenings, 5s.; colliery, small, 4s. 6d.; smiths' coal, 6s. 6d. Patent fuel, 10s. 6d. Pig iron: Scotch warrants, 44s. 11d.; hematite warrants, 45s. 11d., f.o.b. Cumberland; Middlesbrough, No. 3, 36s. 2d. prompt; Middlesbrough hematite, 44s. 1d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails: Heavy sections, £4 10s. to £4 15s.; light sections, £4 15s. to £5 5s. f.o.b. Tin-plate bars, £3 17s. 6d. to £4. Siemens tin-plate bars, best £4 5s. to £4 7s. 6d., all delivered in the district, cash, less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 3d.; Siemens coke finish, 9s. 6d. Ternes, per double box, 28 by 20 c., 21s. to 22s. Pitwood, 16s. to 16s. 3d. London Exchange telegram: Copper, £41 2s. 6d.; Straits tin, £58 17s. 6d. Freights firm.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, January 3rd.

THE latest transactions in steel billets in 1000 ton lots are 19 dols.; wire rods, in small lots, 27 dols.; steel rails are dull, at 28 dols.; beams, 1·70; angles, 1·55; plates, 1·60; refined bars, 1·35; best, No. 1 F, 14 dols. These quotations can be shaded in favour of large buyers. Very few care to act just now. The future of prices is uncertain, although there is very little room for decline. Telegraphic advices to-day from Pittsburgh show more inquiry for billets and slabs. Similar advices from Cleveland say Lake ore prices for 1896 are virtually fixed. There is considerable anxiety among manufacturers owing to the long delay among buyers. Usually large orders are placed in December, but the past month was dull. There is danger of a too sudden expansion of demand, as there was last summer. A great many mills have been improved, new machinery and more heating and rolling capacity has been added. Numerous similar changes have been determined upon this year. The chances are that the year 1896 will be satisfactory to the well-situated mill especially. This year's Lake ore production will reach 13,000,000 tons. There is a rumour that another fleet of steel boats will be contracted for. One of the favourable evidences is the improving demand for steam and hydraulic machinery. Locomotive work has increased. Tools and shop equipments are also wanted. The agricultural interests continue to be cautious buyers. The Government will soon start around the world on a begging tour for £20,000,000. The masses of the people are enraged at the men and measures that force this action. Tariff legislation will be passed in the house, be fought in the Senate, and vetoed by the President, who, by the way, is duck shooting just now.

LAUNCHES AND TRIAL TRIPS.

The s.s. Eastlands recently built by Messrs. Rafiner and Son, of Stockton-on-Tees, for Messrs. J. F. Wilson and Co., West Hartlepool, left the Tees on Monday last for her trial trip, having aboard Mr. J. F. Wilson, the managing owner, Mr. Maddison—under whose supervision the steamer has been built—and a large party of friends; after a very satisfactory run the steamer was taken into West Hartlepool to receive her bunker coal to take her round to Maryport, where she will load for the River Plate.

On Monday, December 30th, 1895, the fine steel screw steamer Sui Sang, built by Sir Raylton Dixon and Co., Cleveland Dockyard, Middlesbrough, for Messrs. the Indo-China Steam Navigation Co., went for her official trial trip in Tees Bay, under the command of Captain Galsworthy. The s.s. Sui Sang is 323ft. long by 41ft. beam by 27ft. 6in. depth moulded, and has been built to the requirements of Lloyd's 100 A1 class, spar deck rules, her deadweight capacity being about 4500 tons. The vessel has been specially designed to meet the requirements of the Indo-China Steam Navigation Company's trade in the eastern seas. Spar deck is of steel sheathed with teak, main deck of steel, and the poop, bridge, and forecastle decks are of teak. Large cargo ports are fitted in 'tween decks opposite each hatch. A handsome saloon with accommodation for ten passengers is elegantly fitted up under bridge deck. The captain is berthed in a large teak house on bridge, and the officers, engineers, &c., on bridge deck. Rooms for compasses are fitted up in poop aft. Engines of the triple-expansion type have been fitted by Messrs. the North-Eastern Marine Engineering Co., having cylinders 23in., 36in., 59in. by 42in. stroke, supplied with steam from two large steel boilers fitted with Howden's forced draught. The vessel has been built under the supervision of Mr. Buchanan and Mr. Duncan. A number of friends, including Mr. Cheyne, secretary to the Indo-China Steam Navigation Company, were on board during the trial trip, which passed off most satisfactorily.

On January 3rd the steamers Penarth and Bertholey had their trial trips in the Bay off Hartlepool. The vessels have been built by Messrs. Wm. Gray and Co., for Messrs. Morel Bros. and Co., of Cardiff, and they are the fifth and sixth ships built and engined at Messrs. Gray's works for the same firm. They are both built to Lloyd's highest class. The dimensions of the Penarth are:—Length over all, 336ft.; breadth, 41ft.; depth, 24ft. 10in.; and of the Bertholey, length, 310ft.; breadth, 43ft.; depth, 22ft. 1½in. The hulls are built with web frames, and there is a double bottom under each hold for water ballast. Tasteful saloons and state rooms, together with captains' and officers' rooms, have been fitted. Triple-expansion engines have been supplied by the Central Marine Engine Works of Wm. Gray and Co.; in the one case of 1200-horse power, and in the other of 1000-horse power. Three large main boilers, built of steel, and working at 160 lb. pressure per square inch, have been supplied, and this ample supply of steam enables the donkey boilers to be dispensed with, as one of the main boilers can be kept under steam for working the winches, windlass, &c. The vessels and their machinery have been built under the superintendence of Mr. W. G. Morel and Mr. F. Good. The vessels left the dock at the same time, the party of inspecting engineers going out by tug, and after completing the trial of one boarding the other. The engines were in each case run full speed ahead for an hour to test their capabilities, and the trials were in every way perfectly satisfactory, reversing from ahead to astern being done in four seconds, as is usual with these engines. The trials were witnessed by Mr. Good, on behalf of the owners; Captain Murrell represented Messrs. Wm. Gray and Co.; Mr. T. Mudd, the engine builders. There were also present Mr. Kish, of Messrs. J. and E. Kish, Sunderland, together with Mr. Metcalfe, their inspecting engineer; Mr. Percy Mudd, and others. The vessels were in command of Captains Morgan and West, and immediately on the conclusions of the trials the steamers left together for South Wales to load their first cargoes—the Penarth for South America, and the Bertholey for the Mediterranean.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

23rd December, 1895.

24,559. Engine Cutters and Tracers, G. Iden, Brighton.

24,560. Exhibiting Pictures by Lanterns, W. J. Spurrier, Birmingham.

24,561. Preparing Warp Yarns, T. Pickles and G. Landless, Manchester.

24,562. Adjustable Music Stools, J. W. Deans and W. D. Foster, Selby.

24,563. Multitubular Boiler Efficiency, J. Scott, Jarrow-on-Tyne.

24,564. Covers for Boilers, W. H. Parry and J. H. Powick, Birmingham.

24,565. Fasteners for Windows, C. H. Jones, Glasgow.

24,566. Noiseless Tires for Wheels, C. Challiner, Manchester.

24,567. Pneumatic Gas Regulator, H. G. Mason, Birmingham.

24,568. New Boiler or Water-heater, S. Naylor, Leeds.

24,569. Expanding Crank for Velocipedes, H. J. Warsop, Nottingham.

24,570. Gas Cooking Apparatus, E. W. T. Richmond, Liverpool.

24,571. Gear Cases for Cycles, E. Powell, Northampton.

24,572. Stoppering Bottles, T. Cooper and R. Potter, Portobello.

24,573. Clover-making Machines, F. S. Cocks, Peterborough.

24,574. Signalling Railway Trains, R. Wilby, Huddersfield.

24,575. Horseshoes, W. W. Barnes, Harrington.

24,576. Brace Fittings, C. N. Eyland, Birmingham.

24,577. Supports for Electric Conductors, T. Laurie, Falkirk.

24,578. Electric Tramways, D. Urquhart and F. Wynne, Westminster.

24,579. Gulleys, J. D. Cook, Sheffield.

24,580. Lock Mechanism for Fire-arms, C. H. Maleham, Sheffield.

24,581. Cardboard Folding Boxes, J. E. Thornton, Altrincham.

24,582. Ash Guard and Cinder Sieve, T. E. Jones, Oldham.

24,583. Tobacco Pipes, W. Leggett, Norwich.

24,584. Potato Paring Machine, W. Paulson and T. Willoughby, Derbyshire.

24,585. Roofing Buildings, W. Schmitt and E. Kauert, Glasgow.

24,586. Textile Fabrics, L. Schniewind and A. Schmidt, Germany.

24,587. Mail Cart or Perambulator, H. V. Lloyd, London.

24,588. Bracket for Holding Brushes, S. H. Bath, London.

24,589. Floors for Ice Skating Rinks, E. Hesketh, London.

24,590. Protector for Book Corners, B. J. Saunders, London.

24,591. Mechanism of Chronometers, F. W. Engelbach, London.

24,592. Counter for Type-writing Machines, R. T. Haines, London.

24,593. Photographic Printing Plates, G. Poore, London.

24,594. Electric Lifts, J. S. Stevens and C. G. Major, London.

24,595. Method of Extinguishing Lamps, W. Vint, Surrey.

24,596. Manufacture of Tiles, &c., R. Thorburn, London.

24,597. Ladies' Dress Skirts, J. W. Roberts, London.

24,598. Feed-water Heaters, W. Goodbrand, Manchester.

24,599. Rubber Tires for Wheels, C. S. Stone, London.

24,600. Circulation of Air, J. A. Dargue and E. Griffiths, Liverpool.

24,601. Window Sashes, J. Butterworth and H. Clementson, London.

24,602. Doors, J. Butterworth and H. Clementson, London.

24,603. Puzzle Game, H. Golding, London.

24,604. Sheep Dipper and Washer, E. Besent, London.

24,605. Letter Boxes, F. E. Wiggens, London.

24,606. Cigar Cutter and Holder, G. C. Bingham, Waterford.

24,607. Projectiles, H. Stanbridge, London.

24,608. Firebacks for Stoves, S. B. Goslin, London.

24,609. Lift Valves, C. D. Abel.—(*G. Sulzer, Switzerland.*)

24,610. Working Armour-plated Turrets, J. A. Deport, London.

24,611. Heating Apparatus, F. Rotter, London.

24,612. Counting the Number of Bell Beats, E. French, London.

24,613. Cover for Jars, Pots, Bottles, &c., A. Stute, London.

24,614. Intaglio Plates, J. W. Swan and J. J. Waddington, London.

24,615. Production of Essences, M. Woolf, London.

24,616. Beer Engines, H. Scott, London.

24,617. Toy Figures such as Toy Soldiers, H. M. Paget, London.

24,618. Telephony, C. Adams-Randall, London.

24,619. Preparation of Lupines, Max, Baron von Maltzan and G. Bocker, London.

24,620. Spring Clips, F. W. Golby.—(*L. Kanderer, Germany.*)

24,621. Tires for Carriage Wheels, J. U. Burt, London.

24,622. Safety Valve, C. Mackintosh, London.

24,623. Tap, G. Barnes, T. B. G. Zwicker, and A. Tod, London.

24,624. Bilge Syphon, N. Power and P. Braender, London.

24,625. Valves, E. J. Preston and A. T. Cornish, London.

24,626. Cool Safes and Cool Storage, J. G. Lamb, London.

24,627. A Cleansable Sink, J. Christie, London.

24,628. Draught and Weather Excluder, F. G. Groenert, London.

24,629. Punching Eyelet-holes, W. Downs and H. J. Scott, London.

24,630. Dynamo-electric Machines, W. H. Tregaskis London.

24,631. Furnaces for Bakers' Ovens, J. Matula, London.

24,632. Engine Governors, A. S. F. Robinson, London.

24,633. Pipe Coupling, A. Spencer, London.

24,634. Tires, G. E. Lyons and A. Melson, London.

24,635. Tobacco Pipes, A. J. Boult.—(*Société Vuillard and Strauss, France.*)

24,636. Preventing Explosions in Boilers, J. E. Greaves, London.

24,637. Granular Surfaced Paper, E. A. Zuber, London.

24,638. Doors of Dwelling House, A. Mosley, London.

24,639. Device for Tapering Ends of Candles, W Vogel, London.

24,640. Driving Gear for Cycles, W. F. Fremersdorf, London.

24,641. Photographic Lenses, T. R. Dallmeyer, London.

24,642. Stud for Gloves, F. Micheland, London.

24,643. Removing Stains, J. Y. Johnson.—(*The Firm of S. Wallach and Co., and E. Schweitzer, Germany.*)

24,644. Boot Jacks, R. Jacks, London.

24,645. Car Couplings, P. R. J. Willis.—(*W. E. Whiteside, United States.*)

24,646. Rubber Cushioned Lined Wheels, H. Carmont, London.

24,647. Sailing Yachts, A. Sharp, London.

24th December, 1895.

24,648. Lace Fastener for Boots, A. J. Moore, Malta.

24,649. Joints in Cycles, W. F. Taylor and P. H. Clarke, Croydon.

24,650. Door Mats, F. Baggaley and W. J. Robinson, Manchester.

24,651. Cutting Rashers of Bacon, F. J. Burrell and E. Maxwell, Bedford.

24,652. Packing Cases for Goods, J. G. Chadwick, Chadderton.

24,653. Candle Bracket for Mirrors, R. J. Smith, Bromsgrove.

24,654. India-rubber Eraser, R. J. Smith, Bromsgrove.

24,655. Attaching Together Gloves, S. H. Crocker, London.

24,656. Compasses, L. Myers, Birmingham.

24,657. Air-tight Cans, L. Myers, Birmingham.

24,658. Wheels for Perambulators, G. Moore, jun., Birmingham.

24,659. Measuring Fluid, &c., D. L. Hutchinson, Glasgow.

24,660. Window Blind, T. H. Gray and W. J. Loon, Birmingham.

24,661. Double Stench Traps, I. Russell, Birmingham.

24,662. Embossing American Cloth, A. Gray, London.

24,663. Fire Lighters, F. G. Eaton, Manchester.

24,664. Regenerative Furnaces, L. Moyes, Glasgow.

24,665. Affixing Adhesive Stamps, A. Lewis, Liverpool.

24,666. Manufacturing Acetylene Gas, T. Holliday and J. H. Exley, Bradford.

24,667. Ladders and Portable Scaffolds, J. H. Heathman, London.

24,668. Tiles, S. H. Leech, London.

24,669. Protecting Bank Cashiers, &c., N. B. Rees, London.

24,670. Portable Fire-escape, F. M. Quinn, London.

24,671. Folding Wheel-barrows and Carts, R. R. Thom, Kilmarnock.

24,672. Reducing Valves, G. and J. Horrocks, Manchester.

24,673. Cellular Lifebuoy, H. Wall, Stockton-on-Tees.

24,674. Fireproof Flooring and Roofing, F. B. Bond, Bristol.

24,675. Cycle Brake Attachments, C. R. Hall, jun., Birmingham.

24,676. Tobacco Pipes, G. Craigen, London.

24,677. Protecting India-rubber Tires, T. Criswick, Bridgend.

24,678. Type-writers, J. C. Fell.—(*Messrs. Wyckoff, Seamans, and Benedict, United States.*)

24,679. Attachment to Wheels and Pulleys, S. H. Farrar, London.

24,680. Electric Lighting of Cycles, P. H. Emanuel and H. G. Baker, Portsea.

24,681. Universal Music Indicator, J. W. King, Liverpool.

24,682. Manufacture of Parallel Vices, W. Dangerfield, Darlaston.

24,683. Pneumatic Tires for Vehicles, E. Tilston, Manchester.

24,684. Rails for Railways, T. Andrews, Manchester.

24,685. Nursing Nipples, R. L. Shute, Glasgow.

24,686. Shirt Collar Bands, P. R. J. Willis.—(*M. Kyle, Canada.*)

24,687. Stove Pipes, G. B. Barclay, London.

24,688. Nosebags for Horses, G. Wickes, London.

24,689. Clothes Brush, C. Rose-Innes, London.

24,690. Pulleys, L. S. Carr, London.

24,691. Chain Pipe-wrenches, G. Sonnenthal and H. Bamford, London.

24,692. Clothes Washing Machine, J. S. Kingston, London.

24,693. Shafts of Golf Clubs, T. W. Goddard, Waltham Cross.

24,694. Counters for Boots and Shoes, T. H. Donovan, London.

24,695. Box and Dies, H. J. Loney and A. J. Jung, London.

24,696. Decorticating Rhea Grass, J. MacDonald, London.

24,697. Feeding Water to Steam Generators, W. Birrell, Glasgow.

24,698. Lamp Shades for Billiard Tables, H. Nelmes, Glasgow.

24,699. Clamp for Pipes and Rods, R. J. Lockhart, London.

24,700. Securing Soap in Washrooms, J. H. and J. E. Welch, London.

24,701. Embroidery Plate, P. Fournier, London.

24,702. Railway Switch, &c., The Westinghouse Brake Company.—(*J. P. Coleman, United States.*)

24,703. Galvanising, R. Heathfield and W. S. Rawson, London.

24,704. Pamphlet Covering Machine, B. S. Lewis and A. H. Smith, London.

24,705. Hand Stamps, J. H. Gressitt and H. W. Fox, London.

24,706. Electric Telegraphy, G. C. Marks.—(*W. H. Cooley, United States.*)

24,707. Buttons, N. D. Ingram, London.

24,708. Separating Oil from Water, H. H. Lake.—(*Maschinen-fabrik Grevenbroich, Germany.*)

24,709. Sterilising Apparatus, J. L. A. Aymard, London.

24,710. Lightning Arresters, J. Devonshire.—(*W. B. Potter, United States.*)

24,711. Electric Brakes, J. Devonshire.—(*W. B. Potter, United States.*)

24,712. Dress Fasteners, E. J. A. Babbage, H. Friendship, and T. W. Hicks, London.

24,713. Ring Spinning Frames, J. H. Bourry, London.

24,714. Treatment of Fatty, &c., Substances, A. E. Morgans, London.

24,715. Sand-blast Apparatus, J. E. Mathewson, London.

24,716. Switch for Tramways, L. Pritzius and F. Straube, London.

24,717. Fire-lighters, H. Minuth, London.

24,718. Self-acting Hair Brushes, B. P. Olsson, London.

24,719. Wheels for Bicycles and Vehicles, G. Hayes, London.

24,720. Letter Files, W. P. Thompson.—(*W. A. Cooke jun., United States.*)

24,721. Folding Boxes, W. P. Thompson.—(*W. A. Cooke, jun., United States.*)

24,722. Pavements and Steps, G. T. Fuery.—(*G. Martenstein, Germany.*)

24,723. Tramcars, C. Bremer, London.

24,724. Water-tube Boilers, W. C. and A. W. N. Burder and J. M. Newton, Manchester.

24,725. Pyrotechnic Compounds, W. Weiffenbach, Liverpool.

24,726. Rests for Use in Billiards, W. H. Edwards, Liverpool.

24,727. Climatium Japonicum, C. W. Hartung, London.

24,728. New Washing Machine, H. Kramer, sen., Liverpool.

24,729. Anti-nicotine Pipe Cleaner, T. F. Bevan, Liverpool.

24,730. Rag Engines, C. Seybold and W. Schmidt, Liverpool.

24,731. Railway Time Tables, C. A. Bird, London.

24,732. Ball Bearings, A. Hansen, London.

24,733. Cycle Propelling Mechanism, A. Patchett, London.

24,734. Drinking Vessels, W. I. Thompson, London.

24,735. Electric Arc Lamps, &c., W. H. Smith, London.

24,736. Box for Holding Toilet Paper, P. Herzberg, London.

24,737. Photographic Apparatus, B. J. B. Mills.—(*A. Tournier, France.*)

24,738. Clothes Peg, T. H. Prosser and M. Young London.

24,739. Non-fillable Bottles, E. Anderson, London.

24,740. Bottles, G. E. M. Carleton, London.

24,741. Puzzles, C. E. Morrison, London.

24,742. Side Bed-pan, S. C. Wolfskill, London.

24,743. Pipes, J. M. Grau, London.

24,744. Puzzles, C. B. de Camp, London.

24,745. Envelopes, J. J. Lussier, London.

24,746. Non-fillable Bottles, J. L. Wolf, London.

24,747. Pins, L. R. Bisbee, London.

24,748. Non-fillable Bottles, D. Hepp, London.

24,749. Driving Mechanism for Gill Boxes, J. V. Sprangh, London.

24,750. Fire Indicating Apparatus, W. H. Trimble, London.

24,751. Steam Engines, J. S. Raworth, London.

24,752. Paper Cutting Machines, T. B. Kendell, London.

24,753. Steam Engines, C. Sheppard, London.

24,754. Panels for Decorating Houses, W. McLaren, London.

24,755. Horticultural Buildings, H. T. Grainger, London.

24,756. Revolution Counters, A. J. B. E. Darras, London.

24,757. Tobacco Pipe, E. Ropp, London.

24,758. Supporting Bicycles, M. P. M. Collier and W. McArthur, London.

24,759. Horseshoes, A. Falstead and D. A. Davidson, London.

24,760. Bee-hives, K. von Nemesszeghy, London.

24,761. Diving Bells, R. Haddan.—(*J. E. Whiting, India.*)

24,762. Inclinometer and Level, F. Wetzelsberger, London.

24,763. Horseshoe Pads, W. E. Jennings, London.

24,764. Vehicle Wheels, C. Lofmark, London.

27th December, 1895.

24,765. Trammel Compass, R. L. Donkin, Pocklington, Yorks.

24,766. Perfection Skirt and Belt Holder, L. Taylor, London.

24,767. Candlestick, H. N. Shore, Clevedon, Somerset.

24,768. Umbrella and Camp Stool, P. and P. J Weston, Bristol.

24,769. Apparatus for Cleansing Streets, D. Mackie, London.

24,770. Underground Chambers, C. M. Sansom and F. I. Spinks, London.

24,771. Tea Packing Cases, G. F. Dewdney, Cardiff.

24,772. Printing on Underclothing, R. Greenhalgh, London.

24,773. Flat and Tubular Articles, J. T. Pearson, Burnley.

24,774. Condenser Carding Engines, J. D. Tomlinson, Manchester.

24,775. Steam Generators, W. Munro, Newcastle-on-Tyne.

24,776. Cutting Tapered Slots, W. Lister and J. Cardwell, Newcastle-on-Tyne.

24,777. Roofing Tiles, F. A. Krause, Manchester.

24,778. Fishing Reel, J. W. Young, Redditch.

24,779. Colouring Matters, I. Levinstein and Levinstein, Ld., Manchester.

24,780. Pulley Racks for Roller Blinds, G. Hayes, Southampton.

24,781. Weaving Looms, R. L. Hattersley and S. Jackson, Bradford.

24,782. Head Lock for Bicycles, C. W. Burrows, Birmingham.

24,783. Treatment of Spent Oxide, J. H. Paul, London.

24,784. Heel and Toe Tips for Boots, D. A. Berry, Manchester.

24,785. Book Sewing Machines, H. Liebert, Manchester.

24,786. Capstan Lathes, H. Liebert, Manchester.

24,787. Recovering Oil from Waste, G. E. Wright and W. Monk, Manchester.

24,788. Brake Appliances for Carriages, J. J. Broadbridge, Manchester.

24,789. Printing Woven Fabrics, S. Schwabe and Co. and J. Gilbertson, Manchester.

24,790. Mental Telepathic Assistant, E. Mulliner, Southport.

24,791. Cinder Sifter, F. W. Lewis and J. W. Paulton, Wolverhampton.

24,792. Gas and Explosive Vapour Engines, J. E. Rogers, Birmingham.

24,793. Door Bolt, E. G. Hentsch, Sunderland.

24,794. Removable Coal Catcher, P. Jay, London.

24,795. Supplying Water to Spinning Frames, J. Cleland, Down.

24,796. Valve for Pneumatic Vehicle Tires, E. B. Raper, York.

24,797. Machines for Topping Turnips, J. Munro, Glasgow.

24,798. Handle-bar for Cycles, &c., A. W. McMurdo Glasgow.

24,799. Spirit-Vapour or Gas Engine, W. Hewitt, Ayrshire.

24,800. Electric Light Adapters, J. B. Meiklejohn, Glasgow.

24,801. Fire-arms, W. H. Dorman, Stafford.

24,802. Girths for Horses, A. Pottie and J. McCreery, Glasgow.

24,803. Obtaining Metals from Ores, L. Pelatan and F. Clerici, London.

24,804. Rail-aided Cycle, H. J. S. Winslow, London.

24,805. Mangling Machines, W. B. Mair and J. Lindsay, Glasgow.

24,806. Preventing Pocket Picking, B. Strobal and R. Singer, Glasgow.

24,807. Mariners' Compass, H. Florian and H. Schoklitsch, Glasgow.

24,808. Binding Hats, Bradbury and Co. and C. Shaw, Manchester.

24,809. Metallic Bedsteads, T. M. Hewitson, Acocks Green, Worcester.

24,810. Water Heating Apparatus, J. Jameson, Newcastle-on-Tyne.

24,811. Cycle Seats, P. A. L. Pryor and N. G. Thompson, London.

24,812. Metallic Breakwater or Wave Breaker, G. Defosse, Brussels.

24,813. Drop-down Guns and Rifles, J. W. Smallman, Nuneaton.

24,814. Drop-down Guns and Rifles, J. W. Smallman, Nuneaton.

24,815. Bolt-making Machinery, P., S., and J. McFarlane, Glasgow.

24,816. Metallic and Composite Boxes, P. S. Brown, Glasgow.

24,817. Mills, H. Mecke and The Eisenwerk (vorm. Nagel and Kaemp), A. G., London.

24,818. Machine for Measuring Flour, W. R. Clarke, London.

24,819. Baths, A. E. Browning, Birmingham

24,820. Securing Watches, F. W. Hince, Birmingham.

24,821. Finishing Felt Hats, H. H., A., and A. Turner, Manchester.

24,822. Construction of Waistcoats, M. S. Forster, London.

24,823. Coke Furnaces, H. Stinnes, Germany.

24,824. Screening Coals or Minerals, F. Berkley, London.

24,825. Book-binding Operations, W. Wilson, London.

24,826. Gas Burners, T. Holliday, London.

24,827. Cauterising Apparatus, W. P. Thompson.—(*The Actien Gesellschaft fur Feinmechanik vormals Jetter and Scheerer, Germany.*)

24,828. Water Gauge Glasses, W. P. Thompson.—(*J. Pissinger, Germany.*)

24,829. Ventilators for Mines, T. Marsden, Liverpool.

24,830. Utilising Tidal Power, W. J. Roberts and J. R Jones, Liverpool.

24,831. Roller Blinds, Shutters, O. Bayer, Liverpool.

24,832. Transit of Fat, W. and W. W. McNaught and Co., Liverpool.

24,833. Kettles, R. B. Arthur, London.

24,834. Electric Accumulators, C. Théryc and A. Oblasser, London.

24,835. Apparatus for Filtering Liquids, W. Raydt, London.

24,836. Electrically Operated Windlasses, G. Asmussen, London.

24,837. Washing Akali-amalgam, P. Jensen.—(*H. C. F. Störmer, Norway.*)

24,838. Mattresses, &c., B. J. B. Mills.—(*O. Paxcal, France.*)

24,839. Atmospheric Gas Burners, J. Moeller, London.

24,840. Apparatus for Making Oil Gas, J. Moeller, London.

24,841. Separable Boats, H. Lefevre, London.

24,842. Colouring Matters, C. D. Abel.—(*The firm of L. Durand, Huguenin and Co., Switzerland.*)

24,843. Portable Advertising Device, D. Foster, London.

24,844. Shells, G. Kynoch and Co., and E. Jones, London.

24,845. Construction of Ceilings, F. Schweitzer, London.

24,846. Cash Registers, A. J. Boult.—(*The Rochester Cash Registry Company, United States.*)

24,847. Explosives, W. Greaves and E. M. Hann, London.

24,848. Fluoride of Antimony, H. H. Lake.—(*O. O. B. Froelich, United States.*)

24,849. Harness Traces, W. and J. W. Pinder, Lancashire.

28th December, 1895.

24,850. Tires for Cycles and other Vehicles, J. S. Martin, Dundee.

24,851. Telephone and Phonograph, J. E. O. Kumberg, London.

24,852. Material for Electrical Purposes, W. P. Adams, London.

24,853. Saddles for Cycles, L. T. Lewis, London.

24,854. Milk Steriliser, W. Robinson, Wolverhampton.

24,855. Apparatus for Heating Water, A. Foster, London.

24,856. Knitting Machines, R. Challands, F. W. Pare, and J. H. Smith, Nottingham.

24,857. Textile Loop, A. and A. E. Walker, Huddersfield.

24,858. Kiln Hook for Pottery, J. Maddock, Staffordshire.

24,859. Pedals of Cycles, &c., H. Lewis, Birmingham.

24,860. Means for Filling Crates, W. L. Pilkington, Liverpool.

24,861. Cutting Coal, F. J. H. Lascelles, Newcastle-on Tyne.

24,862. Construction of Anchors, J. Donald, Barrow-in-Furness.

24,863. Back for Fire-places, A. Macpherson, Edinburgh.

24,864. Fire-lighters, S. Learoyd, Huddersfield.

24,865. Boots and Shoes, &c., S. Learoyd, Huddersfield.

24,866. Spindles, B. A. Dobson.—(*A. Kirschner, France.*)

24,867. Boilers, W. Cuthbertson, Glasgow.

24,868. Recording Instruments, W. Thomson and B. Kelvin, Glasgow.

24,869. Construction of Lining Tunnels, C. Barlow, Glasgow.

24,870. Joint for Pipes, W. J. Given, Glasgow.

24,871. Brakes, W. Fairweather.—(*O. Quadri, Italy.*)

24,872. Metallic and Composite Boxes, P. S. Brown, Glasgow.

24,873. Valve Instruments, W. Harris, Vermont, U.S.A.

24,874. Handle-bar, C. A. Allison.—(*J. C. Jackman, United States.*)

24,875. Designs upon Carpets, R. J. C. Mitchell, Manchester.

24,876. Erasers, P. Pinckney, Portsmouth.

24 877. Machine for Levelling Roads, J. Heuermann, London.

24,878. Drills and Undercutters, J. A. Derham, Preston.

24 879. Apparatus for Testing Drains, W. H. Temple, London.

24,880. Metal Surfaces, J. E. Mathewson, London.

24,881. Bicycle Rim, J. H. Kydd and J. B. Mitchell, Canada.

24,882. Folders of Printing Machines, B. J. J. Goulding, London.

24,883. Letter-files, Indexes, &c., C. F. Lomb, London.

24,884. Automatic Switch, J. W. and G. Ewart, London.

24,885. Controlling the Supply of Gas, J. R. C. Gale, London.

24,886. Photographic Camera, I. de Balás, Birmingham.

24,887. Asbestos Filters, C. D. Abel.—(*B. Blumenfeld, Austria.*)

24,888. Joints for Electrical Purposes, G. W. Goldring, London.

24,889. Cycle, J. Santiquet, London.

24,890. Ladles for Molten Metal, W. Hainsworth, London.

24,891. Gas Engines, E. Gathmann, London.

24,892. Electric Machines, P. R. Jackson and Co., and J. S. Lewis, London.

24,893. Pneumatic Tires, J. Oliver and L. Fletcher, Liverpool.

24,894. Wringing Machines, J. Barnes, R. W., W. H., and A. Kenyon, Manchester.

24,895. Electric Machines, P. R. Jackson and Co., and J. S. Lewis, London.

24,896. Supporting Scaffolds, J. Edwards and The Coalbrookdale Co., Liverpool.

24,897. Separating Water, J. A. Morris and W. T. Hatch, Manchester.

24,898. Manufacture of Cement, &c., M. Nahusen, London.

24,899. Water-tube Boilers, N. Foley, London.

24,900. Confectionery Coating Machines, J. R. van Derveer, London.

24,901. Boots Soles and Heels, R. Poore, London.

24,902. Dust Excluders, W. T. Hall and W. J. Bayliss, London.

24,903. Breech Mechanism of Ordnance, E. Donn, London.

24,904. Back-pressure Valves for Drains, W. Shoosmith, London.

24,905. Telephone Transmitters, T. J. Rorke, London.

24,906. Necktie Retainers, L. W. F. N. and B. I. Sauer, London.

24,907. Kilns for Burning Bricks, J. Phillipps, Ampthill.

24,908. Paper Fasteners and Label Holders, S. Learoyd, London.

24,909. Pneumatic Tires for Cycles, P. Reidel, Berlin.

24,910. Material for Flooring Rooms, P. Reidel, Berlin.

30th December, 1895.

24,911. Hand Carts, J. E. Neal, Derby.

24,912. Wheels for Warehouse Trucks, A. Dugdale, Manchester.

24,913. Weighing Machine, E. C. Lovell and H. Brecknell, Bristol.

24,914. Moistening Yarn, J. T. Pearson, Burnley.

24,915. Sashes and Doors, A. Rhodes and C. Gill, Keighley.

24,916. Steam Generators, J. J. Tinker, Manchester.

24,917. Mariners' Compass, W. D. Whyte, Glasgow.

24 918. Sights for Fowling Pieces, J. E. Martin, Glasgow.

24,919. Lighting Railway Carriages, J. Mulligan, Sheffield.

24,920. Producing Ammonia, &c., A. McDougall, Southport.

24,921. Apparatus for Inserting Papers into the Folds of Textile Piece Goods, F. Riley and E. O'Connor, Manchester.

24,922. Braking Gear of Cycles, A. E. Hopkins, Chesterfield.

24,923. Manual Pumps, W. Ambler, Bradford.

24,924. Cartridges and Firing of Guns, F. Wynne, London.

24,925. Cycles, W. Woodhead, C. Ford, jun., and J. Wood, jun., Rochdale.

24,926. Hydraulic Machinery, F. Bamford and W. Wadsworth, Manchester.

24,927. Engravers' Chucks, G. Christie, Glasgow.

24,928. Modifying the Transparency of Ivory, C. Raspe, Berlin.

24,929. Cycle Wheels, J. Chaffaud and J. H. Konter, Marseilles.

24,930. Lamp Brackets for Bicycles, F. T. Harrop, Birmingham.

24,931. Parlour Game, E. H. Prew and H. F. Boughton, Barnsley.

24,932. Tobacco Pipe Mouthpieces, &c., J. Y. Fulton, Newport, Mon.

24,933. Roofing Tiles, H. A., G., H. St. R., E., K., and M. S. R. Rumbelow, and G. Hall, Worlington, Suffolk.

24,934. Tobacco Pipes, J. Bush and H. J. W. Raphael, London.

24,935. Scholars' "Acme" Companion, G. H. Pilling, Bacup.

24,936. Gloves for Driving and the like, R. M. Hogg, Glasgow.

24,937. Potato Digger and Sorter, A. J. Macarthur, Glasgow.

24,938. Making Golf Balls, R. J. Hatton, North Woolwich.

24,939. Clip for Holding Wooden Brakes, C. F. Hollis, Shanklin, Isle of Wight.

24,940. "Trilby Puzzle," S. Napper and M. B. Tomkins, London.

24,941. Stay or Corset Busks, &c., L. Kumpfmuller, London.

24,942. Leg Coverings, W. J. Ford, London.

24,943. Sewage Filtering Apparatus, T. B. Jones, London.

24,944. Oil Cans, S. S. Bromhead.—(*F. T. Tolley, Australia, and A. J. Tolley, England.*)

24,945. Carbon Holders for Arc Lamps, H. J. Fisher, London.

24,946. Manufacturing Boots and Shoes, D. Hefferon, London.

24,947. Cistern Valves, E. H. Thornett, London.

24,948. Making Heels for Boots and Shoes, W. Prust, London.

24,949. Electric Arc Lamps, S. S. Allin, London.

24,950. Making Leather, A. K. Y. Anderson and J. Mackintosh, London.

24,951. Flexible Shafting, A. Marotte, London.

24,952. Walking-sticks, F. Bigland and J. Chandler, Liverpool.

24,953. Stopping Engines, A. Spelling.—(*J. S. Yabuley, Japan.*)

24,954. Bicycle Locks, S. H. Patterson, London.

24,955. Puzzles, W. E. Sharp, London.

24,956. Sash Balances, J. H. Bane and L. Brodeur, London.

24,957. Advertising Blocks, O. L. Owen, London.

24,958. Steam Rams, J. P. Randerson and J. M. Seward, London.

24,959. Bottles and the like, J. and E. Stretch, London.

24,960. Sea Signalling, G. J. Pieters and I. Selten, London.

24,961. Angle Joint for Revolving Shafts, S. H. Crocker, London.

24,962. Driving Gear, H. H. Lake.—(*J. Pethely and H. F. Hambruch, Germany.*)

24,963. Safety Device for Perambulators, H. Conitzer, London.

24,964. Yarn Chains, A. G. Brookes.—(*H. F. Straw, United States.*)

24,965. Pulleys, J. G. Lorrain.—(*A. D. Thomas, United States.*)

24,966. Cutting Sweetstuff, G. Prokofiew and M. Streimer, London.

24,967. Producing Marble-like Stucco, M. Hoeft, London.

31st December, 1895.

24,968. Tanning, J. B. Scammell and E. A. Muskett, London.

24,969. Cycle Saddles, C. Creyke, London.

24,970. Umbrella and Parasol Device, J. P. Kinsela, Cork.

24,971. Chain for Reducing Friction, E. Hewer, Eastleigh.

24,972. Pendants for Lighting Purposes, E. J. Shaw, Walsall.

24,973. Dabbing Brushes, J. V. Musgrave and F. Scott, Bradford.

24,974. Engine Governors, W. Swindell.—(*E. Woods, South Africa.*)

24,975. Metallic Travelling Sheet, W. Whiteley, Huddersfield.

24,976. Drying Hanks of Yarn, W. Whiteley, Huddersfield.

24,977. Hubs of Cycles and other Vehicles, W. King, jun., London.

24,978. Driving Gear, L. Callender and A. E. Ragg, St. Helier's.

24,979. Pipes, E. M. Anderson, Glasgow.

24,980. Degerming Maize, W. M., J. A. D., and N. MacG. MacKean, Glasgow.

24,981. Measuring Liquids, J. Hare, Manchester.

24,982. Toe Pieces for Horseshoes, B. Watkins, Birmingham.

24,983. Saucepans, L. J. Painter, Glasgow.

24,984. Pipe, W. Place, Southport.

24,985. Clip Brackets, J. R. F. Flemming, London.

24,986. Tobacco Rolling Machines, B. Hammond, London.

24,987. Railway Carriage Windows, R. Denny, jun., Glasgow.

24,988. Holder and Price Indicator, F. E. Salsbury, London.

24,989. Castors, D. E. Hand, Birmingham.

24,990. Applying Manumotive Force, G. Quick, London.

24,991. Holder for Billiard Cues, A. C. Strains, London.

24,992. Ladders, A. G. Perkins, London.

24,993. Calendars, J. T. Hoare, London.

24,994. Speed Gearing for Cycles, W. H. Miller, London.

24,995. Corset Busks, W. Edwards, London.

24,996. Coin-freed Apparatus, R. T. and J. G. Glover, London.

24,997. Covers for Cleaning Eyes of Drains, G. Hyde, London.

24,998. Oil Stoves, H. W. Wright, London.

24,999. Warp Stop Apparatus, A. G. Brookes.—(*W. F. Draper, United States.*)

25,000. Combustion of Fuel, S. Bender and T. Micoch, London.

25,001. Vapour Condensers, S. G. Merrick and H. L. Washburn, London.

25,002. Electrolytical Apparatus, R. Heathfield and W. S. Rawson, London.

25,003. Bottles, J. Boyd, London.

25,004. Ship's Rudder, W. R. Lawson, London.

25,005. Obtaining Gold from Antimony, W. J. Studds, London.

25,006. Perfuming Articles of Dress, H. J. Dunn, London.

25,007. Machines for Making Cigarettes, J. S. Detrick, London.

25,008. Staple Driving Machines, W. S. Ashbey, London.

25,009. Making Oxide of Lead, H. H. Lake.—(*T. Benfield, United States.*)

25,010. Door Securing Devices, H. H. Lake.—(*F. A. Potter, United States.*)

25,011. Control Mechanism, A. J. Boult.—(*— Stanwood, ——.*)

25,012. Wrenches, S. W. Wardwell, jun., London.

25,013. Plastic Composition, W. L. Woods, London.

25,014. Cash Registers, J. B. Benton and E. B. Hess, London.

25,015. Screw Tipping Gear for Wagons, The Bristol Wagon and Carriage Works Company, Ld., and J. Macdonald, Bristol.

25,016. Lamp Globes, G. C. Marks.—(*C. F. Brown, United States.*)

25,017. Marking Tags, W. P. Thompson.—(*C. J. Weinman and E. E. Eschenhofer, United States.*)

25,018. Mortising Machines, W. P. Thompson.—(*C. Cristadoro, United States.*)

25,019. Massage and Electro-massage, G. Rossbach, London.

25,020. Water-closet Seats, W. S. Wallace, Liverpool.

25,021. Filters, M. Hilton, Manchester.

25,022. Self-oiling Bearings, P. R. Jackson and Co., Ld., and J. S. Lewis, London.

25,023. Purifying Red Oxide of Iron, G. H. Smith, Liverpool.

25,024. Engine Stops, J. Livingston, London.

25,025. Mops, C. Newcome and W. R. Popplewell, London.

25,026. Cane Planters, A. M. Rivero, London.

25,027. Music Holding Appliance, J. R. Collings, London

24,028. Securing Wheels to Axles, A. M. Clark.—(*W. F. McQuivey, United States.*)

25,029. Pneumatic Tires for Cycles, A. E. Sayers, London.

25,030. Trapping Animals, G. Andrews, J. W. and H. V. Briginshaw, London.

25,031. Car Wheels, W. J. Taylor, London.

25,032. Preparing Type or Matrices, O. V. Sigurdsson, London.

25,033. Water-tube Steam Generator, F. G. Hampson, London.

26,034. Valance for Bedsteads, &c., M. I. Major, London.

25,035. Door Bell and Gong, A. Latto, London.

25,036. Sleepers, P. R. J. Willis.—(*O. T. Bedell, United States.*)

25,037. Planer, M. J. Campbell, London.

25,038. Lighting Device for Cigars, V. Lalanne, London.

25,039. New Cycle Bell, M. Weatherhead, London.

25,040. Closing of Preserve Bottles, P. C. Borde, London.

25,041. Scissors, T. Slater, London.

25,042. Fire-arms, C. H. R. Clausius, London.

25,043. Printing Machines, W. M. Rockstroh, London.

25,044. Studs or like Fasteners, J. F. Cornish, London.

25,045. Indicating the Weight of Fabrics, M. H. Tomkins, London.

25,046. Carriage Buffer Couplings, S. J. Warsap, London.

25,047. Hoppers for Casks, J. W. Flower and R. J. Cousins, London.

25,048. Punching Bags, E. A. Hawthorne and H. Sheble, London.

25,049. Rotary Calcining Apparatus, D. A. Peniakoff, London.

25,050. Propelling Aerial Vessels, E. J. Pennington, London.

25,051. Water and Steam Valves, W. Thomson, Baron Kelvin, Glasgow.

25,052. A Gilders' Triple Press, F. W. Vickery, London.

25,053. Portable Electric Lamp, R. T. and J. G. Glover, London.

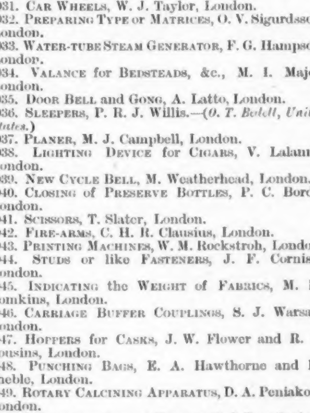
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

547,414. Gas Engine, *J. J. Bordman, Brooklyn, N.Y. —Filed February 3rd,* 1894.

Claim.—(1) A gas engine having in combination a casing provided with a combustion chamber, extending around it a power wheel within the casing, means for igniting the gas and a water jacket, extending around the inner circumference of the combustion chamber, substantially as specified. (2) In a gas engine. the combination with a casing, having an annular combustion chamber, of a power wheel within the circumference of said chamber and having blade-like spokes forming chambers, and ports leading from the interior of the wheel to the combustion chamber, the openings of said ports within the wheel being arranged in different circles, one relatively to the other, whereby the explosive element will be discharged into the combustion chamber, but once during the revolution of the wheel, substantially as specified.

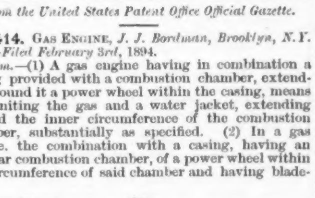
547414



547,441. Electric Bicycle, *H. W. Libbey, Boston, Mass.—Filed October 9th,* 1894.

Claim.—(1) A bicycle consisting of a front driving wheel and a rear double tread steering wheel connected together by a loop frame, an electric battery and an electric motor secured to said frame between the wheels, the motor being under the battery and gears, cranks and connecting-rods to transmit motion to cranks on the axle of the driving wheel, substantially as set forth. (2) In a bicycle the combination with a frame of an electric battery and an electric motor secured to said frame, a longitudinal tube extending from the front to the rear fork and forming a tank to hold exciting fluid for the battery, substantially as set forth. (3) In a bicycle the combination with a frame of an electric battery and an electric motor secured to said frame a longitudinal tube extending from the front to the rear fork for holding the exciting fluid for the battery, an electric controlling device, suitable connections between the battery, motor and controlling device, and suitable mechanism for transmitting motion from the motor to the driving wheel, substantially as set forth.

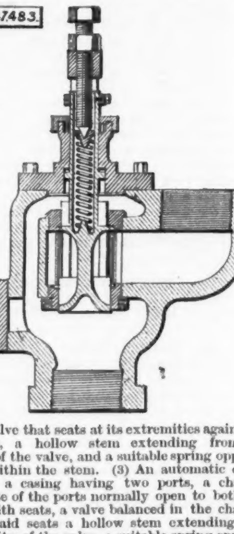
547441.



547,483. Cut-off, *J. H. Dousman, Milwaukee, Wis.—Filed December 19th,* 1894.

Claim.—(1) An automatic cut-off comprising a casing having two ports, a chamber intermediate of the ports normally open to both and provided with seats, a valve balanced in the chamber to oppose said seats but having its extremities of differential area to external fluid pressure, and a suitable spring arranged to exert its power on that extremity of the valve having the least area to said pressure. (2) An automatic cut-off comprising a casing having two ports, a a chamber intermediate of the ports, a cage having one head thereof overlapping the chamber and its other head extended through the same, a clamping ring in screw thread engagement with the latter head of the cage against said chamber, an internally balanced valve that seats at its extremities against the cage heads, a hollow stem extending from one extremity of the valve, and a suitable spring opposing the valve within the stem. (3) An automatic cut-off comprising a casing having two ports, a chamber intermediate of the ports normally open to both and provided with seats, a valve balanced in the chamber to oppose said seats a hollow stem extending from one extremity of the valve, a suitable spring opposing the valve within the stem, and a collar on said stem movable in a recess within the casing.

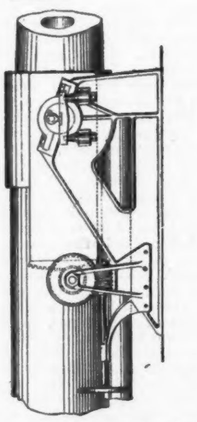
547483.



547,507. Apparatus for Mounting Guns, *J. Strauss, U.S. Navy.—Filed January 4th,* 1895.

Claim.—(1) In a gun mounting, the combination with a gun, and trunnions to stand the shock of recoil, of knife edges secured to said trunnions to sustain the weight of the gun, and supports for said knife edges, substantially as described. (2) In a gun mounting, the combination with a gun, and trunnions adapted to stand the shock of recoil, of knife edges secured to said trunnions, to sustain the weight of the gun, and vertically adjustable supports to said knife edges, substantially as described. (3) In the gun mounting, the combination with a gun, and trunnions to stand the shock of recoil, of knife edges secured to said trunnions, blocks supporting said knife edges, and screws connected to the gun carriage and adjustably supporting said block, substantially as described. (4) In a gun mounting, the combination with a gun, of knife edges which support the same at approximately the point about which the gun is turned for elevating and depressing, and means which limit the longitudinal movement of said knife edges relative to their bearings on the recoil of the gun.

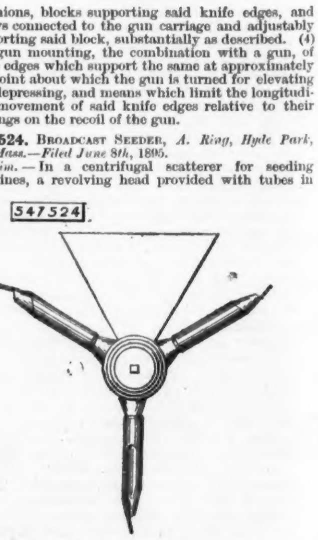
547507



547,524. Broadcast Seeder, *A. King, Hyde Park, Mass.—Filed June 8th,* 1895.

Claim.—In a centrifugal scatterer for seeding machines, a revolving head provided with tubes in combination with adjustable telescoping sections, carrying fan-shaped distributing points, substantially as shown and described

547524



NAVAL ARCHITECTURE.—A FEW PRINCIPLES POPULARLY EXPLAINED.

No. I.—DISPLACEMENT.

FROM time to time numerous inquiries reach us in regard to the meanings of terms employed by naval architects when discussing or describing the qualities of a vessel, and we are often asked to explain how these qualities are determined. For instance, in the answers to correspondents contained in our issue of 11th October last, there will be seen the reply which was given to one of these many inquiries. In this case, as in numerous others, it was impossible to give a complete answer to the question within the limits of space at our disposal for such a purpose. Some of these inquiries relate to abstruse problems in naval science, but the greater number of them are of a simpler character, and admit of a more or less clear explanation in general terms, such as may be understood by the ordinary reader. In view of the demand thus evinced for information of the character we have indicated, it has been thought desirable to present our readers with a few articles devoted to an explanation of some of the common terms employed in naval architectural science, as well as to the methods whereby some of the qualities of a vessel are determined. In seeking to treat these matters popularly we do not, of course, suppose that the articles will be of any service to those already employed in shipbuilding and ship design; but to the apprentice and junior draughtsman they may perhaps serve somewhat to clear the way for further and more exact study. It is, however, for the layman pure and simple, from whom the great bulk of inquiries come, that we intend principally to write.

Let us commence, then, with the question of a vessel's displacement, which was partly answered in THE ENGINEER of 11th October, and discover what further can be said in simple terms in the way of explaining how the displacement is calculated. In our reply to "Shipbuilder"— a *nom de plume*, by the way, adopted by one who never built a ship—we said, "The displacement is obtained by calculating the volume in cubic feet of the immersed body of the vessel, and then dividing the result by 35, which is the number of cubic feet of sea water weighing a ton." Now, if the immersed body were of some regular form, such as a rectangular box or any other figure of which the cubical contents admit of ready and exact computation, the determining the displacement would be a very simple matter indeed. It is because the immersed surface of a ship is not of a regular form, and the volume enclosed by it is not determinable by any of the rules of mensuration, that the task of calculating that volume is so intricate and laborious.

In proceeding to show how the calculation is made, let us begin with a rectangular box—Fig. 1 — floating, with four sides vertical, and therefore with the bottom horizontal and parallel to the plane of the water surface. If this box be 7ft. long, 5ft. broad, and float with a depth of 2ft. immersed, then its displacement will be $7 \times 5 \times 2 = 70$ cubic feet. Suppose it to be floating in sea water, which weighs a ton per 35 cubic feet, then it is evident that the box in question with its contents will weigh $\frac{70}{35} = 2$ tons, and two tons are, therefore, the displacement of the box at a draught of 2ft. This is a very simple case; being simple just because it is so easy to calculate the area of a rectangle, and the volume of a rectangular cube. The only regularity about a ship's form consists in its being symmetrical—or, in other words, both sides being alike. Hence, if we can calculate the immersed volume of one side, we have only to multiply the result by two to get the whole. But that does not help matters much, seeing that the one-half is of so peculiar a form for measuring and calculating.

FIG. 1

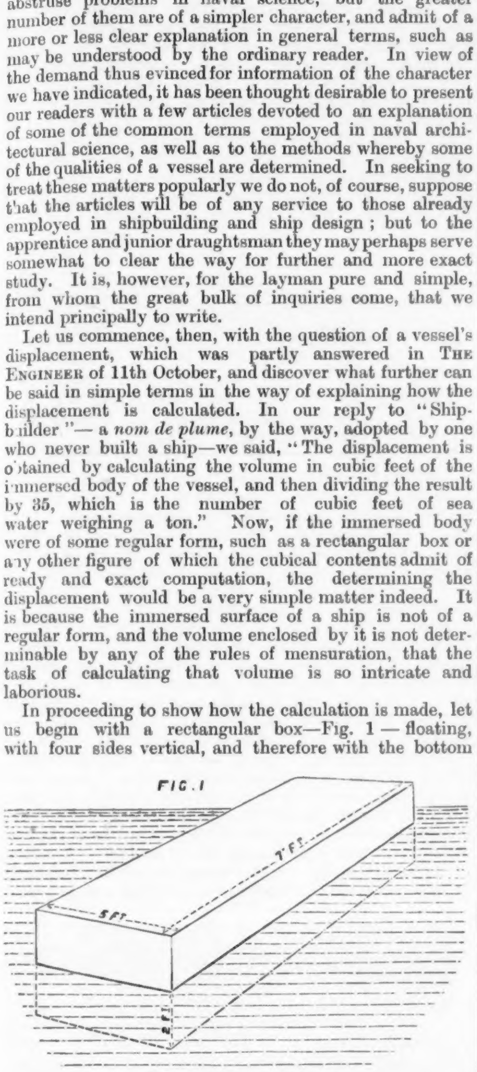


Fig. 2 shows a transverse section of our rectangular box, and within it is the midship section of a ship-shape vessel of the same breadth and depth. The ratio which the area of the vessel's section below water bears to that of the circumscribing rectangle is termed by naval architects the "coefficient of fineness of midship section." That "ratio" or "coefficient" will vary from about ·5 in pleasure craft to about ·9 in cargo carrying tramp steamers. Transverse sections of the vessel and circumscribing box taken at places nearer the bow and stern will show greater differences in the two areas, and, therefore, lesser ratios or coefficients.

FIG 2

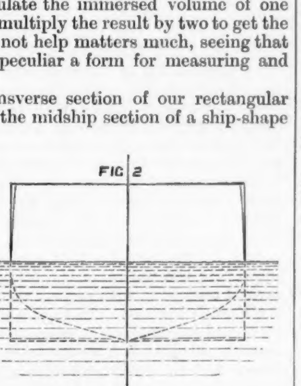

Fig. 3 shows a middle line longitudinal vertical section of vessel and circumscribing box, and there the difference in area between the two below the water surface is very little; but at parallel plane sections further from the middle line the differences become continually greater.

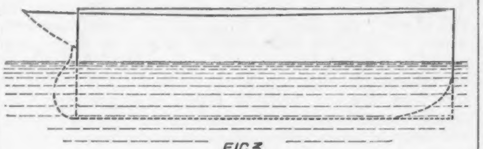

FIG. 3

Fig. 4 shows a horizontal section of vessel and circumscribing box at the water surface, and the ratio between the two is called the "coefficient of fineness of the load water plane." This coefficient will range from about ·85 in a bluff cargo steamer to about ·75 in a steamer of fine form. The parallel sections below the water-line of the vessel, as shown in the figure, become smaller and smaller in area in approaching the keel, and therefore their ratios, or coefficients, diminish in the same way as do the vertical sections towards the bow and stern. The ratio which the volume of the entire body of the vessel below water bears to that of the circumscribing cubical box is called the "coefficient of fineness of displacement," and varies from about ·6 to ·8 in ordinary sea-going steamers. Hence if the coefficient of fineness of a ship-shaped body circumscribed by the box 7ft. by 5ft. by 2ft. be ·75, then 2 tons × ·75 = 1·5 tons, which is the displacement of the ship-shaped body in question, and the fact of floating at a mean draught of 2ft. will show that the weight of the vessel and what she is carrying at that time is 1½ tons.

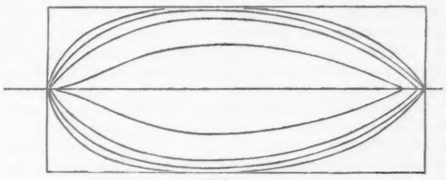

FIG. 4

But the coefficient of fineness cannot be determined until the displacement has been first calculated. Our only reason for referring to it at this stage is to call attention to the fact that a vessel's form, as shown by the three sets of sectional planes, is continuously diminishing towards her extremities in relation to the rectangular outlines of the same plane sections of the circumscribing rectangular box.

Supposing we were to cut up the ship into a great number of thin vertical slices, parallel to the midship slice shown in Fig. 2, making the slices so thin that for all practical purposes their two plane sides would be of equal area. Supposing, also, that we could calculate the area of each such slice. Then in that case the volume of each slice would be obtained by multiplying the area of one of its sides by its thickness, and the volume of the whole immersed body of the vessel would be the sum total of the volume of all the thin slices.

Or, once more, suppose we cut the vessel into a great number of thin horizontal slices parallel to the slices at the water plane shown in Fig. 4. By adding together the volumes of all these horizontal slices we would also get the volume of the entire immersed body of the vessel, and the result would be necessarily the same as was obtained by summing the volumes of the thin vertical slices.

Now this is precisely what the naval architect does in computing the displacement of a vessel; but he goes about it in a way that to the ordinary observer would wholly disguise what he was doing.

Let us see, then, what he does, and why he does it. To do so, we must go back to an elementary curved form, and try to discover a way of getting its area.

Consider the plane surface bounded by the straight line A B, and the curved line A C D E F G B, shown in Fig. 5. This may represent the half water plane of a vessel. Divide A B into an even number of equal lengths—say six—at the points H J K L M, and set up vertical lines or ordinates from these points intersecting the curved line at the points C D E F and G. Join these points by the straight lines AC CD DE EF FG and GB, and it will then be seen that these short lines enclose within them and the line AB a right-lined polygonal figure, the area of which approximates more or less closely to that of the entire figure circumscribing it. Moreover, the greater the number of divisions made in the line AB, and the greater the number of ordinates drawn from the dividing points, the more closely do the two areas approximate.

Let the lengths of the ordinates be represented by the letters *a b c d e f* and *g*, and let the common distance between the ordinates, termed the "abscissa," be represented by x. Then the area of

$$\text{H A C} = \frac{a+b}{2} \times x;$$

$$\text{of C H J D} = \frac{b+c}{2} \times x;$$

$$\text{of D J K E} = \frac{c+d}{2} \times x;$$

$$\text{of E K L F} = \frac{d+e}{2} \times x;$$

$$\text{of F L M G} = \frac{e+f}{2} \times x;$$

$$\text{of G M D} = \frac{f+g}{2} \times x.$$

In Fig. 5, the value of a and g are zero; but in Fig. 6 the end ordinates are shown of a small length. The principles involved, and the methods pursued are, of course, the same in both cases.

Summing these areas we have total area of polygonal figure A C D E F G B

$$= \frac{x}{2}(a + 2b + 2c + 2d + 2e + 2f + g)$$

and this area approximates closer and closer to that of the circumscribing figure bounded by a curved line, just as we increase the number of ordinates and, therefore, diminish the value of x, the common distance between them.

We have thus investigated what is known as the "trapezoidal rule" for the calculation of such figures as that of a vertical or horizontal half-section of a ship; which rule is stated thus:—

Add the end ordinates to the sum of twice the intermediate ordinates, and multiply the result by one half the common distance between the ordinates.

This gives, however, at the best but a rough approximation to the area required, and consequently something closer must be sought. The trapezoidal rule has been stated here because it illustrates the principle underlying the method actually adopted by naval architects, viz., that of close approximation; the result obtained being nearer and nearer the truth, just as the number of ordinates is increased and the length of the common interval between them is diminished.

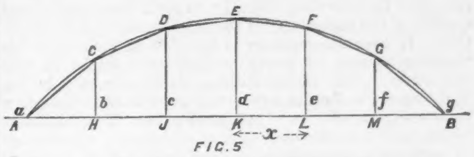

FIG. 5

The properties of the conic sections is a subject too extensive for discussion here; but two statements may be made in regard to it.

In the first place the curved lines of a ship do not depart materially in their character from the curves of the conic sections; and in the second place the areas bounded by curves of the conic sections, and straight lines can be approximated to very closely indeed by the application of a formula or rule, which admits of statement in a manner analogous to that of the "trapezoidal rule." The rule used by naval architects as applied to the case shown by Figs. 5 or 6 is thus expressed:—

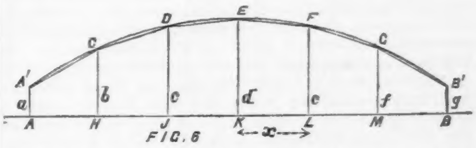

FIG. 6

Area $= \frac{x}{3}(a + 4b + 2c + 4d + 2e + 4f + g)$ and is stated thus:—Divide the base line A B into an even number of equal lengths, from which set up ordinates, which will necessarily be odd in number. Multiply the length of each of the even ordinates by four and that of each of the odd ordinates by two, except the first and last or bounding ordinates, which multiply by unity. The sum of these products multiplied by one-third the common interval between the ordinates will give the area required.

In this way, then, the naval architect calculates the area of each of the equidistant horizontal sections, parallel to the water plane, into which the model or drawing of half the immersed body of the ship is divided. Having found each area separately by this rule, he treats these areas as ordinates and multiplies them by two when even ordinates, by four when odd ordinates, by unity when end ordinates, and finally multiplies their sum by one third the common interval between the water planes and so obtains the entire volume of immersion.

Or, similarly, he may first calculate the area of each of the equidistant sections—see Fig. 7—parallel to the midship section into which the same model or drawing is divided. Taking, for instance, the case of Fig. 7, the common interval between the horizontal planes is y, and the area of the figure A C D E F B is

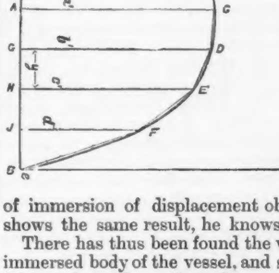
$$\frac{y}{3}(a^1 + 4b^1 + 2c^1 + 4d^1 + e^1).$$

In this instance the value of e is zero.

Having found the area of each vertical section in this way they are treated as ordinates, and the rule applied, as before explained, to determine the whole volume of immersion.

The naval architect calculates that volume in both of these ways, using each as a check upon the other. When the volume of immersion of displacement obtained by each method shows the same result, he knows that it is correct.

FIG 7



There has thus been found the volume of one half of the immersed body of the vessel, and so, on multiplying it by two, we have the entire volume. If the unit of measurement used throughout our calculation has been 1ft., then the result will be in cubic feet, and when the total in cubic feet has been divided by 35, we have the displacement of the vessel in tons. That is to say, we have the weight of a body of sea-water at 35 cubic feet to the ton, equal in volume to that of the immersed portion of the vessel. This is, therefore, the weight of the vessel and all she contains when floating in sea-water at that immersion.

FAILURE OF THE GREAT DAM AT BOUZEY.

The total or partial failure of important hydraulic engineering works of magnitude is fortunately rare, although instances are not wanting, both at home and abroad, which forbid the assumption that they are either unassailable or indestructible. The calamity which so grievously afflicted the inhabitants of the Department of the Vosges in France is a convincing, and, at the same time, a lamentable proof that dams of masonry, as well as those of earthwork, are not exempt from perils of a grave, and sometimes of a disastrous character. Experience has previously demonstrated that the occurrence of a similar catastrophe is not restricted to any particular sphere of action, but constitutes a contingency to which the people of every country in the world are liable. The very possibility of accidents of so terrible a nature, however rare they may be, indicates the urgent necessity for providing liberally, in both the quantity and quality of the materials, for the requirements of construction. If ever an engineer is justified in increasing his working margin of safety beyond what might be considered adequate under ordinary conditions, it is in the building of the dam of a reservoir capable of impounding millions upon millions of gallons of water. English dams, which have hitherto been almost exclusively constructed of earthwork, as a rule have stood well, though a few of the most notable failures, both at home and abroad, will be subsequently referred to. Whether the cause be due to the theoretical or practical conditions—that is, whether to the employment of a better profile, or shape of dam, or to superior workmanship and choice of materials—may be left to experts to decide. The fact remains that the failures of the dams of reservoirs in England have been neither so frequent nor so disastrous in their results as similar accidents in foreign countries.

To find a parallel at home to the destruction of property and the loss of life which was occasioned by the failure of the dam of the reservoir at Bouzey, near Epinal, it will be necessary to go back thirty-one years. A few particulars of this great disaster, in reference to the subject under notice, may not be uninteresting. It was caused by the bursting of the dam of the Bradfield reservoir, in the neighbourhood of Sheffield, on the night of the 11th of March in the year 1864. The suddenly-liberated volume of water swept away with irresistible fury every obstacle and impediment, whether natural or artificial, which opposed its impetuous career, drowned animals in thousands and carried death to 260 human beings. It will be at once apparent that the results of the inundation at Sheffield were precisely the same as those generally described as occurring in the dam near Epinal, but on a scale of greater magnitude. No analogy exists between the two dams themselves, since the one in France was built of masonry, and that at Bradfield was composed of earthwork, with a maximum height of 95ft. At the subsequent inquest held at Sheffield, the evidence of the professional experts, which attributed the failure to the objectionable and unsound practice of laying the naked cast iron outlet pipes through the earthen embankment, was so preponderating as to leave no reasonable doubt on the matter. When pipes are thus laid, the water, in spite of the best puddling and the adoption of all necessary precautions, will "creep" along their outside surfaces, and if the mischief be not checked, which is a very difficult and troublesome operation to effect, the downfall of the dam becomes sooner or later inevitable. *Apropos* to this peculiar "creeping" action of water, an eminent engineer has expressed his belief that where ordinary drainage tiles are laid in a clay, that is, in a puddle subsoil, they drain as much by their external surfaces as by their internal capacity, and that there is a "creep" on every pipe along the outside surface. It is worth mentioning that the result of the inquest led to the general abandonment of the principle of laying naked pipes through an earthen dam. The "Report" of the Commission charged with the duty of investigating the causes which led to the failure of the French dam on 27th April of this year has just come to hand, together with the views of the Department of the Ponts et Chaussées on the whole subject. We shall refer to this Report more in detail presently.

It will be first necessary to recapitulate briefly the principal dimensions of the French dam, not merely for the sake of comparison with other examples, but in order to point out that it was not quite so stupendous a construction as has been assumed. It was designed to form an impounding reservoir, to supply with water the Eastern Canal, and to contain, in round numbers, 7,000,000 tons of water. The length was 1545ft., the height above the bed of the channel 49ft. 3in., and the total height above the foundation 75½ft. At the top the width was 13ft., and at the bottom 39ft., and the façade of the dam was perfectly straight throughout its entire length, or it may be described as straight in plan. The largest dam, or, to speak more correctly, the dam forming the largest reservoir in the world, and thus impounding the largest supply of water, is known as the San Roque dam. It was constructed to furnish a supply of water for the purpose of irrigating the lands in the neighbourhood of the city of Cordoba, in which is situated one of the termini of the Central Argentine Railway. This dam has a height of 115ft., and the water, when it was first constructed, stood at a depth of over 100ft. in it. The reservoir has a storage capacity of 260,000,000 tons, or rather more than thirty-seven times that of the example at Bouzey. As a proof of the comparatively enormous storage capacity of the San Roque reservoir, it may be mentioned that it exceeds by 30,000,000 tons the combined capacity of twenty-four out of the twenty-six largest reservoirs in the world. It should be stated that this dam has not stood as well as it should have done. A year ago very serious defects were discovered in it, and it is not considered safe to allow the water to rise in it higher than 72ft. Even when the water is at this height the reservoir will hold 56,000,000 tons, which is more than double the capacity of any single one of the largest reservoirs either in Europe or in Algeria. As the San Roque dam is situated at no great distance from the city of Cordoba, the bursting of it might lead to an appalling catastrophe, involving the loss of many thousands of lives, and in comparison with which all previous calamities of a similar description would be reduced to very small proportions. It is not at all reassuring—although *absit omen*—for the future of this dam, that one built at Habra in Algeria, and very closely resembling it in height, in shape, bad materials, and inferior construction, collapsed after a brief existence of ten years. A breach in the dam, 330ft. in length by 110ft. in height, was made by the escaping flood, which swept away a large portion of the town of Perregaux, several villages, and destroyed 210 lives. Similar disasters attended the dams at Grand-Cheurfos and Sig, also in Algeria.

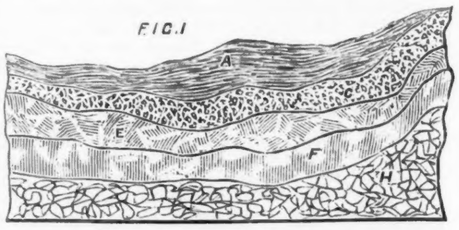
It may be assumed, in the comparison of different dams, that the foundations are adequate in all of them, and therefore the effective relative heights of the dam wall, which will obviously be proportional to the depth of water impounded, constitute the true criterion of this dimension. The effective height of the French dam, judged by this practical standard, is barely 50ft., which is not half that of the similar work at San Roque, which, as will be subsequently shown, is not the highest dam constructed by a good deal. The dam of the Beetaloo Reservoir, built in one of the driest districts in South Australia, has a height of 103ft., and 118ft. was given to the Tansa dam, which impounds 51 million tons of water for the potable and domestic supply of the city of Bombay, and has a length of nearly 9000ft. As an example of the reputed highest dam actually constructed, the Furens dam, situated in the "Gouffre d'Enfer," which supplies St. Etienne with water, may be quoted. It impounds a head, that is, a depth of water, of 164ft., thus completely throwing into the shade not only the dam near Epinal, but all the other examples alluded to. This height, great as it undoubtedly is, will be surpassed by the Quaker Bridge dam across the Croton Valley at New York, to which it is proposed to give a height of 270ft. The stowage capacity of the impounding reservoir formed by it will amount to 31 thousand million gallons.

It should be stated that the French dam was straight, and not curved from end to end, and it has been suggested that the failure might be attributed to this cause. It is, however, a mistake to suppose that the requisite amount of stability and security cannot be given to a straight as well as to a curved or slightly arched dam. It would, perhaps, having regard to the length of the dam at Bouzey, have been advisable to give it a small curvature along the face, and, as nearly all the dams in France are curved, it is not quite apparent why the usual practice should have been departed from. The Tansa dam may be quoted again in support of the statement respecting the security of straight dams, since it is laid out in two straight lines, meeting at a very small angle, nearly at the centre or half way. Each of these separate halves is, therefore, perfectly straight, and the length of each is only a little under three times that of the entire length of the French dam. It is deserving of notice that two of the engineers engaged on the design for the Quaker Bridge dam were strongly against the adoption of the curved form, and recommended a straight line instead. They were opposed by other of their *confrères*, who were equally urgent in their support of a slightly-curved dam. America has not been exempt from failure of works of this character. More than a hundred occurred in a very short period, including those at Danberry, New Redford, Mill River, and Worcester. That at Conemaugh, in May, 1889, about ten miles from Johnstown, in the United States, was a very lamentable affair, closely resembling in its general features the disaster at Sheffield, and the recent failure in France. Probably the most remarkable specimen of construction of the description under consideration is to be found in the Bear Valley dam in California. It is 48ft feet in height above the foundations, only 3ft. thick at top, and 8½ft. at base, and resembles an obelisk far more than a dam. No wonder that an eminent engineer remarked that he would not care to live in any town situated at a lower level in proximity to it.

Nearly all dams are really designed and built on the principles which govern the straight form, and the curvature is added—or "thrown in," as it were—to increase their resistance. There is only one dam in France which acts strictly on the arch or curved principle. It is stated to be 120ft. in height, but of the insignificant length of 200ft. It is called the Zola dam, and was constructed by the father of the present well-known novelist. The Villar dam impounds the water supply for Madrid, and is curved on plan. A terrible catastrophe attended the collapse of the dam of Puentes, early in the present century. It was situated at Sorca, a town on the river Guadalentin, about fifty miles by rail from the seaport of Cartagena, and the bursting of it cost the lives of over 600 of the unfortunate population. The Gileppe in Belgium and the Vyrnwy in England are the first examples of dams constructed of masonry in their respective countries. The Vyrnwy dam is founded on the solid rock, and it has one feature quite unique in such construction, which is that it is the first high dam built to act as a weir. Thus it practically becomes its own weir, and does not require the services of a separate byewash. Both the Belgian and the English dams are generally considered to have an excess of material in them; or, in other words, that they have a superabundant amount of strength. Even so; but, having due regard to the great and important interests involved in the construction and maintenance of these works, and the calamities attending their failure, the right course is to err—if it is erring—on the safe side, and provide *ab origine* for contingent evils, which, should they subsequently occur, are frequently well-nigh irreparable.

Ever since the dam at Bouzey became a *fait accompli* it has not enjoyed a good record. Commenced in 1878, the building of it occupied a couple of years, and during the execution of the works, it was proposed to raise the total height some 6½ft. more than was contemplated in the original design. It should be stated here that the department of the Ponts et Chaussées set its face against this proposition, but it was overruled by the Minister of Public Works, and the alteration was sanctioned. The filling of the reservoir began towards the end of 1881, and even at this incipient stage of future service, springs were discovered on the down stream side of the structure yielding a leakage of 900 gallons per minute. About a year afterwards two fissures made their appearance. From this period until March, 1884, the water was maintained at a height of 2½ft. below what was regarded as its normal safe level. On that date the dam suddenly gave way, and slid on its base horizontally for a distance of 450ft. At the same time the flow from the springs increased to 1700 gallons per minute. Notwithstanding this ominous state of affairs, the water in the reservoir was maintained at the level already mentioned until the following year, when the water was run off, and an investigation into the causes of the slip took place. Before detailing them, we may quote an actual example of the failure of a dam from this very reason. It occurred about two years ago in Texas, when a dam of masonry exceeding 60ft. in height gave way. An inspection of the fractured structure indicated in a manner that left no room for doubt that the water had forced its way through the soft seams of the rock, upon which the dam was founded, and had exerted an upward destructive force that was irresistible. Similarly to the Texas dam, that at Bouzey was not carried down to the solid rock. An examination of the slip of the French dam revealed the existence of a large horizontal fracture extending along a length of 300ft., together with a number of vertical cracks and fissures, and a partial breaking up of the substratum under the foundations to a maximum depth of 10ft.

FIG.1



The accident was due to the fracture of the wall, and the pressure of the water which had found its way underneath. In 1889 the works undertaken to repair and strengthen the dam were concluded, and in so short a period as two months, when the masonry must have been perfectly green, the refilling of the reservoir was commenced, and was carried to a height of 6ft. above the level attained at the time of the slip in 1884, and within 2ft. of the maximum water level possible. The result of this pressure was to cause the down stream face to deflect from the normal straight line to the extent of ⅛in. The circumstances attending the disastrous failure of the dam in last April are well known to our readers. A portion of the central section, 520ft. in length and 35ft. in height, gave way, and in this length was included a large part of the length which succumbed nine years previously. It would appear as if the first accident had established a permanent weak spot in the whole structure. It was also discovered that in those places in which the old stonework had been toothed and racked off, to make a good bond with the new work, there was a considerable amount of disintegration and chipping of the masonry, especially on the down stream face. It appears from the report that the actual pressure per unit of area upon the masonry was considerably less than that obtaining in the dams Gouffre d'Enfer, and in others at Ternay and Chatrain. Two important conclusions were also arrived at. One was that the profile of the dam was so designed that the curve of pressure was not situated in the middle third of the wall, and that the stonework in the up-stream face was subjected to stresses of tension. The report deals lightly with the former consideration, clearly regarding it more as a measure of prudence than an absolute necessity, and there are no doubt numerous retaining walls of many descriptions in which this proviso is either ignored or neglected. There is but one opinion respecting the second point, but it is alleged that in the instance under notice the tensile stresses were so small that they might be neglected with perfect safety.

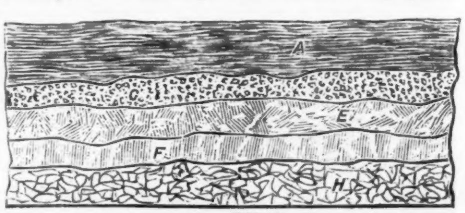


FIG.2

It is a little singular that complete silence is observed respecting the nature of the foundations, the more so as several criticisms with respect to them have appeared in the French journals. In Figs. 1 and 2 are represented a cross and longitudinal section of the valley in which the dam is situated. A peaty layer A forms the top soil. Beneath it lie sandy and alluvial deposits C, and underneath them come the sandstone and schist E. Underlying the last-mentioned is a bed of rough, porous sand and grit stone F, and beneath this a more compact, but by no means a solid stratum of sandstone G, upon which the work is founded. It is not until a depth varying from a minimum of 10ft. to a maximum of 18ft. is attained that the actual solid rock is reached. Under these conditions it is, perhaps, pardonable not to have carried the foundations down to the rock, as the expense would have been excessive. It is certainly a notable feature that the ultimate failure of the structure should have occurred at the exact spot in which was located the previous fracture. The conclusion to which the Commission arrived was the following:—The stonework of the dam was exposed to stresses of tension which exceeded its powers of resistance in consequence of the bad bond made between the old and new masonry work. The same cause gave rise to a long horizontal fissure where the underpinning was executed. The pressures due to the effect of the oblique fissure made at the time of the slip in 1884, and also of the long horizontal fissure, brought about the failure of the dam. The Report concludes with some advice respecting precautions to be taken in similar instances of partial failure, but they are not relevant to the immediate subject before us.

After hearing the opinions of its different members, the Department of the Ponts et Chaussées observes as follows:—It remarks that the raising to a further height of 6¼ft. of the dam and its contents was contrary to the views expressed by the department. It further considers that that circumstance, combined with the influence of the fissures subsequently produced, especially the horizontal fissure arising from the defective bond in the old and new masonry, was one of the principal causes of the catastrophe. The views of some of the members of the department of the Ponts et Chaussées are rather singular. It is put forward by one that the failure of the dam was due to exceptional circumstances which were beyond all human foresight, and that the accident was really owing to a powerful manifestation of that mysterious agent *force majeure*. In addition to the conclusions arrived at, there is very little doubt but that the rapid and decidedly premature filling of the reservoir after the first failure was, at the least, a very injudicious proceeding. As the pressure of water increases, so does the tendency to cause deflection in the face line of the dam, and also to augment the dimensions, the breadth especially, of the fissures. After the French dam was in use, after undergoing repairs, the deflection increased from ⅜in. to ⅞in., and the fissures widened proportionally. One result of deflections in a dam is to cause stresses of tension in the material, and, should they pass certain limits, they may give rise to cracks, or even produce openings at the joints.

Seismic agency, as well as the action of severe frost during the winter preceding the collapse of the French dam, have both been advanced as causes of the collapse. A German scientist suggests that a sudden and exceptionally high tide in the Avière, caused a powerful reflux of a large volume of water into the reservoir, which, conjoined with other causes, might have brought about the failure. It is admitted in the French technical journals that instead of Portland cement, lime mortar, *chaux du Theil*, was used in the actual building of the dam, some parts of the face of which were plastered with the thinnest possible veneer of Portland cement mortar. One French engineer goes so far as to condemn all dams of masonry, and advocates a return to the old method of building them of earthwork, with the orthodox puddle wall in the centre, basing his views upon the success which has attended the general adoption of that material in our own country. Some idea of the extent of the damage and loss caused by the failure of the Bouzey dam may be gained from the fact that £230,000 are needed to replace all that it is possible to replace.

STEAM LOCOMOTIVES ON COMMON ROADS.

By W. FLETCHER.

THE following paper is a sequel to that concluded on page 315 of the last volume of THE ENGINEER:—

In this article separate locomotive engines intended for drawing an omnibus for passengers, and one or more light vans for goods, will be described. I believe there is a great future for this system of road locomotion, to act as feeders to the railways in our Colonies and foreign countries, where no laws are in force such as we have to contend with in England. As soon as these laws are modified, the same means of communication between the village and town, and between the farm-yard and the nearest railway station, will be used in England also. In this place I shall omit all reference to purely historical examples, but shall describe a few road engines and trains that have been put to actual work in comparatively recent times.

A brief description is given of a small road steamer made by Messrs. Perkins and Son, Regent-square, London. This road engine is of very novel design, and possesses several features of interest. From the engraving Fig. 23,[1] it will be seen that the engine, boiler, and driving gear are mounted on a circular frame, above the single driving wheel; this machinery turns with the wheel in the act of steering. It is claimed for this arrangement that the machine pulls in the direction that it is steered. The engine is coupled to a carriage upon which an atmospheric condenser is placed. The condenser is composed of a number of small pipes, through which the exhaust steam is passed as it leaves the engine, the lower part of the wagon being used as a tank for catching the condensed steam. The following are some of the dimensions of the engine and boiler:—Engines are of the double-cylinder compound type; two high-pressure cylinders, 1⅛in. diameter; two low-pressure cylinders, 3⅛in. diameter; stroke of each cylinder, 4½in. Diameter of the driving wheel is 25in., and 12in. on face. Section of india-rubber tire, 10in. by 5in. thick. The vertical boiler is constructed entirely of thick wrought iron tubes, with welded ends, and is perfectly free from any liability to explosion. The boiler is 26in. high, 15⅝in. wide, and 20⅜in. long. Fire grate area ¾ of square foot. The working pressure is 450 lb. per square inch. These engines have been run at a speed of considerably over 1000 revolutions per minute. The engine only weighs 32 cwt.; the condenser, wagon, and passengers, 52 cwt. It runs on the road at eight miles an hour, without emitting any smoke or steam into the atmosphere, and is practically noiseless. The consumption of coal is only 2 lb. per ton per mile. This high-pressure high-speed minature engine developed 20-horse power when running full speed under a load.

Mr. Thompson's road steamers must not detain us, as these were referred to in Mr. Head's paper.[2] The inventions of Mr. Thompson, undoubtedly promoted steam locomotion on common roads. A considerable number of road steamers were made by Messrs. Burrell and Sons, Thetford; Messrs. Ransomes, Sims, and Head, Ipswich; Messrs. Robey and Co., Lincoln, and others. Many of these were shipped to foreign countries for passenger service. Some particulars of four road steamers made by Messrs. Ransomes are given in a paper read in 1879, by Mr. Crompton, on "The Working of Traction Engines in India," before the Institution of Mechanical Engineers.[3]

Soon after Messrs. Burrell took up the manufacture of Mr. Thompson's road steamer, they very wisely discarded the "pot" boiler, because of the trouble it gave; and substituted in its place the more reliable locomotive type of boiler. The engines were entirely rearranged to suit the altered conditions, and numbers of engines of this type were sent to various parts of the world, mostly for running passengers and light goods at fairly high speeds. An engine of this design was made for the Turkish Government, and described by THE ENGINEER as "one of the best designed road locomotives up to that time constructed."

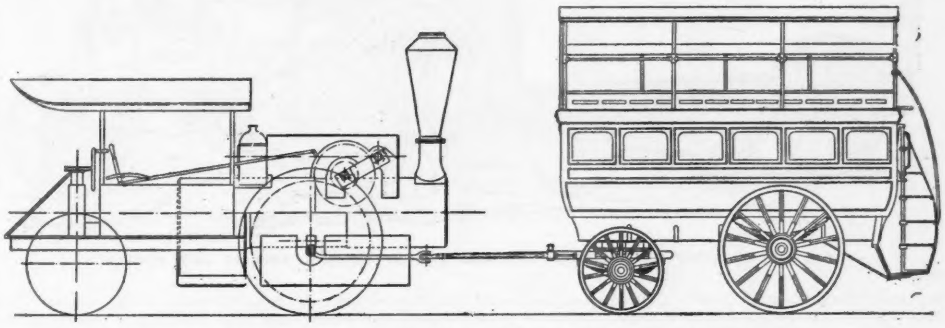

Fig. 24—ROAD STEAMER AND OMNIBUS BY MESSRS. CHAS. BURRELL AND SONS

Fig. 24 shows an outline drawing of a large passenger engine of this class connected to a well constructed omnibus intended for forty passengers. This engine was fully tested in England, and sent to Greece. It will be seen that the engine is mounted on the top of a locomotive multitubular boiler; the cylinders are placed at the fire-box end of the boiler. The coal bunkers, steering column, and boiler are mounted upon a wrought iron frame as shown. This end of the engine leads, the two leading wheels are placed inside the wrought iron frame, and are, like the driving wheels, provided with india-rubber tires properly protected. The driving axle is situated about the middle of the boiler, the chief weight of the engine, boiler, and water tank resting on the driving wheels. Spur driving gearing is employed for transmitting the motion from the countershaft to the wheels. The main axle is fixed, the driving wheels revolve on it, so that no power is transmitted through it. It will be seen that a pinion on each end of the intermediate shaft gears into a spur ring bolted near the periphery of the drivers, by which means the weight of the driving wheels may be reduced. The following are some of the dimensions of this engine:—The two steam cylinders are 7¼in. diameter, and 10in. stroke; the two driving wheels are each 6ft. diameter, and the leading wheels are 4ft. diameter. Two speeds are provided, the ratios arranged for running at four miles or eight miles an hour, according to the nature of the roads. A cab is erected for protecting the driver and steersman from the heat of the sun, or from rain. The engine work is all neatly closed in, so that the working parts are not seen, and are also kept free from dust. The working pressure was 130 lb. per square inch. Several engines of this type were made for quick running; in some instances smaller engines are used, and slight modifications in the arrangement of the parts took place, but in the main the engines were all similarly equipped, and were successful.

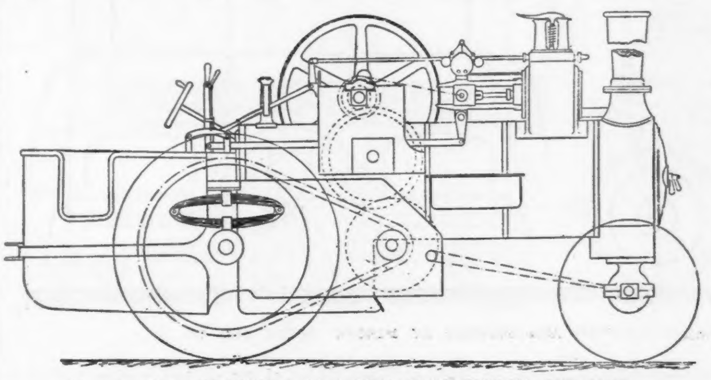

Fig. 25—ROAD LOCOMOTIVE BY MESSRS. CHAS. BURRELL AND SONS

An outline drawing is given of a special road locomotive, recently made by Messrs. Chas. Burrell and Sons. From the illustration, Fig. 25, it will be seen that the countershaft is placed in a line with the main axle, to admit of chain driving, and an efficient method of mounting the heavier part of the engine on laminated springs. The countershaft under the boiler barrel is provided with compensating gear; a chain pinion is attached to each end of this shaft; therefore two driving chains are employed, and the engine answers to the steering wheel, both driving wheels doing an equal share of work when passing along a straight road or when turning sharp corners. This engine was not built for particularly quick travelling, but the silent running driving chains and excellent arrangement of springs render it worthy of note. If a pair of elastic wheels were added, this type of engine would run smoothly on common roads at six miles an hour or more.

The showman finds it to his advantage to adopt a road locomotive for working his steam circus—lighting up the show by electricity, and also as a means of drawing the entire paraphernalia from town to town, the same engine performing the three duties efficiently. Messrs. Chas. Burrell and Sons have constructed some fine compound spring mounted engines for this work, with a dynamo erected over the smokebox. It is well known that the showman has often to cover a good many miles of road during the night and early morning, in order to fulfil his printed engagements. The road locomotives travel well at high rates, irrespective of Acts of Parliament, and do more work than horses could possibly achieve.

Messrs. Aveling and Porter, of Rochester, have manufactured a large number of road locomotives for all manner of purposes. They have been favoured with orders from several European Governments for a number of quick-speed road locomotives for military purposes—the transport of troops and materials. As these road engines and trains are suitable for passenger service, and have been employed in a similar capacity, a few particulars of results achieved may not be without interest. It is twenty-five years since Messrs. Aveling and Porter built the steam sapper No. 1, when a committee of the Royal Engineers made a thorough trial of it. From that time to the present no adverse report has ever been made by the authorities in charge, but an additional engine has been brought every year since the trial took place. Experiments were made during the end of 1893 with some of these steam sappers in Paris, when a speed of twelve miles an hour was reached on ordinary roads.

Lieutenant-Colonel Templer says:—"At present a train of wagons can on the best roads only traverse fifteen to twenty miles a day, while a traction engine would in the same time reel off sixty to seventy-five miles a day."[4] Road locomotives are used in the Italian Army, and by the Swiss Government. In an official report on the employment of road engines in the Russian Army it is stated:—"The road engines, although only a part of them were employed, did not only completely reimburse their purchase money and the cost of maintenance, but brought an actual profit. The road locomotives have received in the military department the right of citizenship, and will, there is no doubt, render great services to that department in future."

"During the Berkshire manœuvres of 1893, eight steam sappers were employed in taking stores and material to Uffington, Idstone, Liddington, and the different rest camps *en route*, being a total tonnage of 356 tons, a distance of 150 miles, and although the engines were of different patterns and age, this service was accomplished without accident and at small cost, which I venture to say fully proves that steam transport by road locomotives for the army and reserve forces would render most valuable service, both in peace and war, and effect an enormous saving to the country." Lieutenant-Colonel Templer goes on to say: "The steam horse consumes only cheap coal or wood, while animal muscles must be renewed with expensive hay and oats. At the halt the engine ceases to require fuel and water, whereas horses require forage and water in the same quantity as when on the march. When the engine does not work it does not eat, and is costing nothing. Again, the horses would be very much harassed with a continuous march, whereas the capabilities of the steam locomotives are at least an average of fifty miles per day, for month after month. The steam sapper Queen came from Chatham to Aldershot—viz., seventy-two miles—in twenty-six hours, and went to its regular work the next morning." It is interesting to note that the modern road locomotive is being advantageously used for many purposes, and are equally successful when applied to the requirements of the army. Some of these road trains are illustrated in Lieutenant-Colonel Templer's pamphlet. A compound traction engine drawing a food van is reproduced by Fig. 26. Messrs. Aveling and Porter's spring arrangement will be illustrated in due course.

Messrs. Robey and Co., of Lincoln, have made a considerable number of road steamers for passenger service in foreign countries. Fig. 27 shows one of these road locomotives, and a two-wheel omnibus. The engine is of the vertical type, as introduced by Mr. Thompson, but Messrs. Robey have carried out many improvements in the details of the engines, suggested by a twenty years' experience. There is certainly something to be said in favour of this type of engine for running light loads at brisk speeds. The chief drawback of the original Thompson road steamer was the "pot" boiler, which was a constant source of annoyance; this has been replaced by Messrs. Robey's patent tubular boiler with satisfactory results. The engine is mounted on three wheels with india-rubber tires 5in. thick, protected by bands of steel plates. Most of the weight is placed over the driving wheels; the single leading wheel is lightly loaded; the engine is steered with ease. An experienced driver can manœuvre these engines with the utmost facility. The engine carries a large water tank. All the working parts are neatly boxed in. A canopy is provided for the driver and steersman. The engines run silently, and very little trouble is experienced in meeting horses on the road when running at eight miles an hour. Messrs. Robey and Co. have supplied some of these engines recently to customers who have had engines of their make in use for nearly twenty years, which is an excellent testimony in their favour.

[3] See "Steam Locomotion on Common Roads," E. and F. N. Spon.

[4] "Steam Transport on Roads, by Lieutenant-Colonel Templer.

The india-rubber tires act as an excellent spring, and are placed where the spring should be situated; that is, in the nearest point to the road, thus saving the machinery from a great amount of wear and tear. The enormous cost of the tires is a great drawback; we may, however, be able to scheme a good wheel possessing the advantages of the rubber tires at much less expense.

Messrs. John Fowler and Co., Leeds, have made a large number of road locomotives that are available for a variety of purposes, and a no inconsiderable number of engines have been sent to the Colonies, suitably equipped for making long journeys at high travelling speeds. Much might be said respecting the success of Messrs. Fowler's engines, but I have only space to give a few particulars. Reference must be made to an 8-horse power compound road locomotive in use in Australia; the owner of this engine resides forty miles away from the nearest township, the locomotive hauls wood and other produce across country without any roads whatever. At one time a river was crossed by the engine and its load; the banks were about 50ft. deep. Journeys of 300 miles are accomplished at good speeds. These engines are provided with an extra tank for carrying a good supply of feed-water; a few sacks of coal or wood can always be thrown on the wagons. The engines are mounted on springs, so as to allow of accelerated speeds on indifferent roads. In a previous paragraph reference is made to the employment of the modern road locomotive by the up-to-date showman.

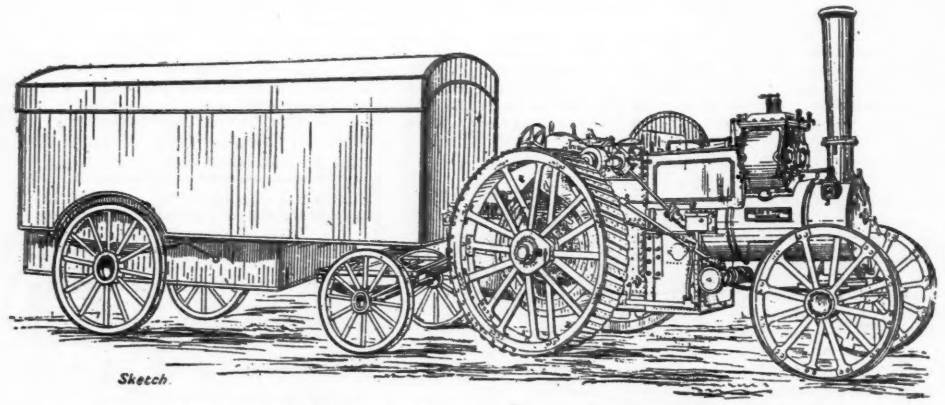

Fig. 26—COMPOUND ROAD LOCOMOTIVE AND VAN BY MESSRS. AVELING AND PORTER

Messrs. Fowler have supplied a large compound road locomotive, which hauls five large vans containing the nameless paraphernalia for a steam circus or roundabout. The engine drives the apparatus during the day time, at night it also keeps the machine in full swing, and drives a dynamo for lighting up the whole show. On the road the engine hauls the five vans and watercart at a good speed up some of the steepest hills in Kent, Surrey, Berks, Bucks, and Oxon. A considerable number of road locomotives are used in many districts for hauling huge boilers, machinery, and other commodities that the railways are unable to carry.

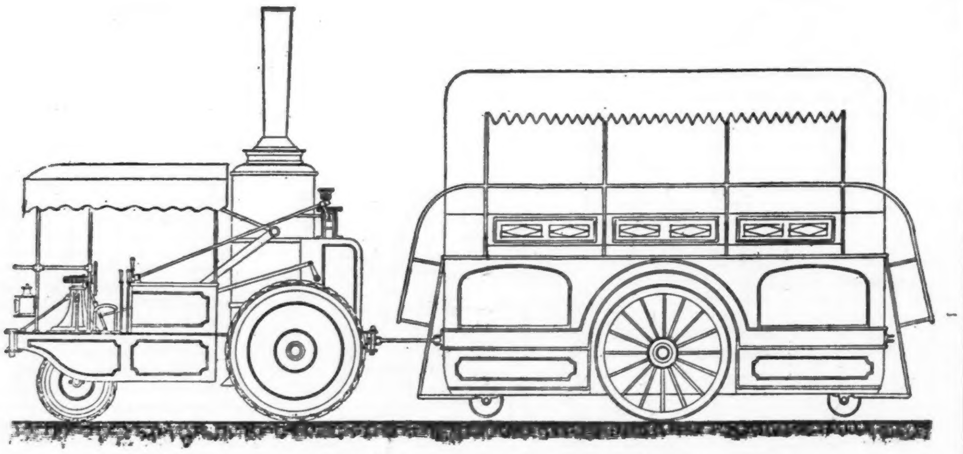

Fig. 27—ROAD STEAMER AND OMNIBUS BY MESSRS. ROBEY AND CO.

By the employment of these road trains some traders are practically independent of the railway companies, and the economy of steam haulage is proved beyond doubt. THE ENGINEER recently remarked:—"Hitherto the transports for the Dover and Canterbury manœuvres have gone by rail; they are now being taken by road by traction engines. It is suggested that traders and farmers might adopt the same system by judicious co-operation. Many classes of merchandise would suffer nothing from the longer time spent in conveyance. The military authorities reckon that they are making a saving of 50 per cent." As an instance of the economy secured by the employment of road locomotives, I may mention the removal of a large boiler which cost £1 15s. If horses had done the work this would have cost over £5, occupying a much longer time and taking up considerable more room. Messrs Fowler's latest form of spring arrangement will be given presently.

Messrs. J. and H. McLaren, of Leeds, have supplied road locomotives and coaches for passenger and light goods service in India, France, &c. In the next article I shall be able to give a side elevation of an engine and train for running a parcel service in France, as described in Mr. John McLaren's paper.[5]

It only remains for me to give some further particulars of the trains, three of which ran regularly between Lyons and Grenoble, which are about seventy miles apart. The parcels were collected and packed into the van during the day; one engine started out of each town in the evening, and delivered its load at the other end the next morning. As the journey has to be made in the night over a very rough and dangerous road, it was important that the engines should be fitted with ample brake-power, a reliable steering gear, and an efficient system of lighting. They were therefore fitted with a steam brake as well as the ordinary hand brake. The steering gear was of the worm-and-rack type. The engines were fitted with an arrangement for burning ordinary gas. One charging of gas was sufficient to give a brilliant head light, and supplied the signal lights for the round trip of 140 miles. These are favourable examples of quick-speed road trains. In addition to the engine of this type, Messrs. McLaren have many other engines doing rather remarkable work.

The Cliffe Hill Granite Company, Leicester, have had two engines at work for several years; these engines make five trips each per day from the quarry to the railway siding, a distance of nearly three miles, carrying 14 tons to 16 tons each trip. They are seldom allowed to stand for half a day. They consider this to be a hard test at continuous working that will be difficult to beat. Another engine at work in Yorkshire on steep hills may be named. The ruling gradients are 1 in 10; one short pinch varies from 1 in 4½ to 1 in 6. The engine takes itself and two empty wagons up this incline easily, and brings down two loaded wagons with 16 tons of stone. It is fitted with an arrangement in the front for raising the smoke-box end of the engine by steam pressure to something like the horizontal position, when descending the hill. It is not only fitted with a powerful brake, but the wagons have double brakes on each set of wheels both back and front. The New Zealand engines for wool-carting continue to give excellent results, but as these engines were dwelt upon in Mr. McLaren's paper, I need not enlarge on this part of the subject. Instances can be given where this maker's engines have more than saved their total cost in one year. In one particular case the use of one of these engines enabled the owners to dispense with fourteen horses. As a rule the use of road locomotives will effect a saving of from 30 per cent. to 70 per cent. as compared with the cost of the same work when horse-power is used. In ordinary circumstances the cost of transport has been reduced to 2d. per ton per mile, and this economy would be still further increased if the engine could be provided with a load both ways.

Enough has been said to show the immense advantage of the employment of the road locomotive for all kinds of work, on all kinds of roads, for slow speeds with heavy loads, or quick speed with lighter roads. Wherever the traction engine has been put to work by competent makers it has always given a good account of itself.

(*To be continued.*)

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.—The annual general meeting of this Association was held on Saturday evening, the 4th inst., at the Cannon-street Hotel, when the balance-sheet was read and approved of, which showed the society to be making continuous steady progress, both in members and funds. The total amount of the funds was stated as £4971, the increase during the past year having been £103. Mr. William Royal was elected president, and Mr. A. K. Douglass vice-president for the present year. The retiring president, Mr. R. J. Cook, gave an address reviewing the proceedings of the past year, and giving some suggestions for future improvements, and a vote of thanks to the retiring officers closed the proceedings.

THE ALBERT RAILWAY BRIDGE AT INDOOROOPILLY, QUEENSLAND.

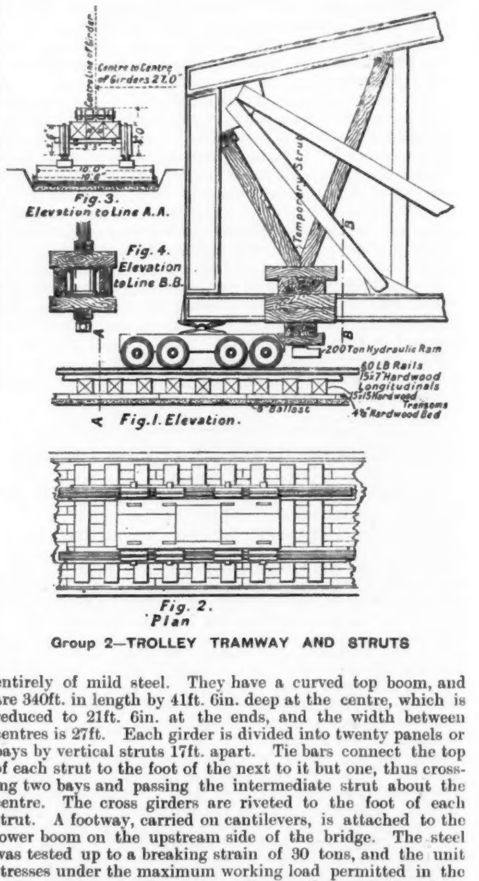
THE Albert Bridge, which we illustrate on page 53 and on page 60, crosses the Brisbane River at Indooroopilly, five miles out of Brisbane City. The river here runs with great force when in flood. In February, 1893, after the phenomenal rains which then fell, all record flood levels were eclipsed, the water covering places which had hitherto been considered well above flood level. Farms, houses, bridges, were all alike swept away before the rushing torrents, and the devastation will long be remembered by the hundreds of ruined inhabitants of Queensland.

Among the many bridges destroyed was the Albert Bridge, and until a new bridge could be built, Brisbane and all the northern parts of the Colony were cut off from direct railway communication with the southern Colonies. The destroyed bridge consisted of eight spans—one of 160ft., six of 80ft., and one of 40ft. The four southern spans were not carried away, although two of the supporting piers collapsed, causing the girders to be balanced on the two remaining piers. Piles were driven to replace the two piers, and this part of the old structure was afterwards used as staging whereon to erect the new southern span.

To cause as little obstruction as possible to the *dèbris* which is down the stream on the flood waters, it was decided that instead of having seven piers in the river as formerly, the new bridge should consists of two spans having only one pier in the river. This pier was built of concrete encased in an iron caisson to low-water mark, then masonry facework with concrete hearting to the bearings of the girders.

The wrought iron caisson was provided to reach the foundation for the centre pier. It was elliptical in shape—see page 53—51ft. across the major axis, and 21ft. 6in. across the minor axis, by 74ft. in height. It has an outer and inner shell of plating 4ft. apart, and well braced together by angle irons. The lower 6ft. of the inner shell was bevelled outwards, meeting the outer shell at the base and thus forming the cutting edge. The space between the two shells was water-tight, and this provided the buoyancy chambers. Concrete was put in these chambers as required to sink the structure. Two cross walls were also provided, which divided the caisson into three wells through which dredging operations were carried on.

The girders for the superstructure—see page 53—are built entirely of mild steel. They have a curved top boom, and are 340ft. in length by 41ft. 6in. deep at the centre, which is reduced to 21ft. 6in. at the ends, and the width between centres is 27ft. Each girder is divided into twenty panels or bays by vertical struts 17ft. apart. Tie bars connect the top of each strut to the foot of the next to it but one, thus crossing two bays and passing the intermediate strut about the centre. The cross girders are riveted to the foot of each strut. A footway, carried on cantilevers, is attached to the lower boom on the upstream side of the bridge. The steel was tested up to a breaking strain of 30 tons, and the unit stresses under the maximum working load permitted in the various members will vary according to the work they have to perform, from 4·5 to 7 tons per square inch.



Group 2—TROLLEY TRAMWAY AND STRUTS

Erection.—Immediately the contract was let the contractors imported new machinery from London, and erected workshops on the river bank, where the whole of the ironwork was manufactured, the raw material only being imported. The first 20ft. of the caisson was built on a slip at the water's edge, from whence it was launched, the remaining portion being built up as the caisson was sunk. Guide piles were driven to keep the structure in its correct position, and so well did they answer their purpose that on completion it was found that the caisson had deviated from the centre line only 2in. From highest flood level the depth of water is 89ft., but at ordinary mean tides it is 42ft. After the caisson was placed between the guides, 33ft. of gravel was dredged out before the rock was touched, and then 3ft. of rock was removed, leaving an even bearing for the caisson. The rock was taken out by divers, the air being supplied by a small compressor. Removing the rock proved a very tedious and hard work, but an excellent foundation was formed. The weight carried on the foundation is between seven and eight tons per square foot.

Launching the girders.—The most important part of the undertaking was the method adopted for building and launching the northern span, as illustrated on pages 60 and 53. It was built partly on shore and partly on piles, see—page 60—it being necessary to build the outer end on piles in order that it might be extended over the water sufficiently to allow the hulk to be floated beneath it. The shore end of the span was carried on two trollies—Group 1, Figs. 1 and 3 of the an-

GROUP 3—STAGING TO CARRY NORTH SHORE GIRDER

nexed engravings—each formed of eight cast iron wheels 2ft. 6in. diameter running loose on 6in. steel axles. The body of each trolley was built with three iron bark timber baulks 18in. × 18in. × 14ft. long, between which were inserted two 18in. × ¾in. wrought iron plates, the whole being securely bolted together and clamped to the axles. These carried the load—140 tons on each trolley—without deflection, and distributed it over 14ft. of the road. On the trollies were placed pivoted bearings for the ends of the girders to rest upon; this allowed for the vertical movement to take place with the rise and fall of the tide. The girders were built high enough to allow the trollies to be placed in position, but as it would be necessary to ease the weight off the trollies to remove them, timber struts—Group 2, Fig. 1—of 20in. diameter iron bark, having their base in front of the trolley, and 8ft. from the end post, were inserted to transmit the load to the various members, and under these struts 200-ton hydraulic jacks were used to free the trollies, and eventually to lower the span the 4ft. necessary to place it on its permanent bearings. The road laid down to carry the trollies—Group 2, Figs. 1, 2, and 3—was over a foundation of clay. It was dug out 10ft. 6in. wide. Six inches of ballast was first laid down, on top of which was laid, breaking joint, sleepers 9in. × 4½in. On the sleepers were 15in. × 15in. transoms 15in. apart, and on the transoms the longitudinal bearers 15in. × 7in. There were two 60 lb. rails on each bearer bolted together, and dogged down every 2ft.

The outer or river end of the span was carried into place on the old barque Jennie Parker, which has a tonnage of 1600 tons, the weight carried by her being about 320 tons, in addition to the weight of the staging and 200 tons of ballast. The ballast was limited to 200 tons on account of the shallow water on the north edge of the river, but to assist in steadying the vessel four booms, weighing ten tons each, and which just floated, were hung to the sides of the ship, and the vessel was braced to the girders by the four steel ropes—1¼in. diam.—as shown, Group 3, Fig. 1. Strong timber towers were built up on the barque, the centre members being carried down to the keelson—Group 1, Fig. 2. The centre of the lifting power was placed under the third strut, or 34ft. from the end of the girders, the thrust being distributed to the second and fourth struts by means of four piles 20in. diameter, and well braced and fixed at the heads similarly to those shown on Group 2, Fig. 2. It was necessary to allow the outer bay to overhang in order that the end pillars would reach their permanent position when the vessel reached the pier. The height of the towers was fixed so that they would reach the under side of the girders at quarter tide. On the day of the launch there was a 4ft. 2in. tide, and when the water had risen 3ft. 6in., it was found that all the temporary packing pieces were free, and that the span was carried on the ship and the trollies only. The outer tiers of piles were thrown over into the river, the operation taking about an hour, and everything was then ready for the span to be moved forward. The barque was moored up and down stream by two cables run out 600ft. and attached to 3-ton anchors, a second cable being run out up stream and attached to two trees, to be available in case of a westerly wind springing up. Four quarter lines were also laid out to help keep the vessel in a correct position. These cables and wires were controlled by winches on board. The hauling power was supplied by a 20-ton hand winch placed on the opposite span and connected to the moving span by a 1in. diameter flexible steel wire rope. A second wire, 1¼in. diameter, attached to the rear end of the girder, to which was rove a six-fold flexible wire tackle hauled by an 8-horse power steam winch, was also provided in case of necessity, but it was not required. The barque was placed under the span at low water 11.30 a.m. on June 29th, and at 4.25 p.m. the launch was commenced, and 90 minutes later the span was landed on the centre pier. At 10.55 p.m. the tide had fallen sufficiently to allow the barque to be removed. The weight of the span as launched was 600 tons.

The southern span was built on the top of the remaining portion of the old bridge, and consequently 5ft. 6in. too high. After completion the chocks were removed except at the two extremities, and the old girders cut away and lowered into punts. The new span was then lowered to its place by means of two 200-ton hydraulic jacks. When the permanent level was reached the span was 5in. too far south. A dozen turned rollers, ¾in. diameter, were then placed between the sole plates of the end pillars, and the bearings and the span were then readily moved forward the required distance by heaving on two 6-ton union screws, the whole operation occupying but 2¼ hours.

The bridge is the largest in Australia which is wholly of colonial manufacture, and it is exceeded only by the Hawkesbury Bridge, which was built in Great Britain. The bridge has given general satisfaction to all concerned, and proves that as good work can be done in Australia as in European countries. The principal quantities of material used are:—Steel in superstructure, 1200 tons; wrought iron in caisson, 250 tons; Portland cement concrete, 3400 cubic yards; masonry, 52,000 cubic feet. The contract price was £66,061. The bridge was designed by Mr. H. C. Stanley, Chief Engineer for Queensland Railways, and the methods of erection, including the launching of the north span, were planned by Messrs. John McCormick and Son, the contractors, under whose personal supervision the entire work was carried out.

On August 17th, before opening the bridge to traffic, it was tested. Each span was built with a camber of 6in. The first test consisted of placing two trains upon each span, each train weighing 260 tons, or 520 tons in all. Under this stationary test the deflection was 1·95in. Secondly, the two trains were run on to the bridge from opposite directions, at a speed of thirty miles an hour, and timed to meet in the centre of the span. Under this test the deflection was 1·68in. When the loads were removed it was found that the deflection was removed also.

MECHANICAL ROAD CARRIAGES.

AMONG the many applications of mechanical road carriages it is expected that the carriage of farm and market garden produce will be one of the most important. and that this is thought probable may be gathered from the article by Mr. F. S. Courtney, M.I.C.E., in the current quarterly journal of the Royal Agricultural Society. Referring to THE ENGINEER offer of prizes and the conditions of trial, Mr. Courtney says:—

> These trials should prove of the utmost interest, as the conditions under which they will be made conform more nearly than those of either of the Paris trials to the requirements of this country. All the most successful petroleum motors in the Paris trials used a light oil with low flashing point. In the above conditions, however, the regulations of the Royal Agricultural Society with regard to petroleum motors are confirmed, and only heavy oils will be permitted. This will necessitate considerable modifications, and it is to be hoped that some of the English manufacturers who have given such attention to working with heavy oil may, before the trials take place succeed in arriving at an efficient and simple combination of carriage and motor. Racing, moreover, is precluded by the regulations as to speed, and this should result in more attention being given to other essential requirements, and in the carriages produced being of a stronger and more useful type than those which might be built merely to run a race over a 200-mile course.
>
> There being no restriction as to the type of motor, it is to be hoped that steam, petroleum, electricity, and compressed air or gas may all find representatives. Though for use in towns, where arrangements might easily be made for re-charging, electricity offers so many advantages in the absolute freedom from smell, noise, and heat, and is so very easily handled, yet in country districts at present it cannot be generally used, since the difficulties as to re-charging would necessitate an excessive weight in the accumulators. This difficulty of re-charging also affects the question of using compressed gas or air in the ordinary way. It would seem, therefore, that for country or agricultural purposes the contest must rest between steam and petroleum, either of which may provide us with a self-propelled vehicle superior to anything yet produced, which shall travel along the roads noiselessly at a speed of not less[*] than ten miles per hour, and shall be under perfect control. Both engineers and carriage builders are busying themselves with its production, and we may be assured that the vehicle will be forthcoming so soon as the restrictions as to its use are removed. To obtain their removal, all interested should be agreed as to the precise nature of the regulations they consider necessary for the reasonable safety of the public, which should, as far as possible, be enforced by the central authority rather than by the various Councils throughout the country.

We may mention that with the object of helping towards a repeal of the existing legal restrictions, the proprietor of the *Autocar* has followed our example and is circulating for signatures a petition to be presented to Parliament.

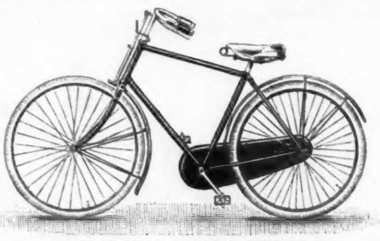
ELECTRIC LIGHTING BY LOCAL AUTHORITIES IN THE METROPOLIS.—The advisability of the establishment of public electricity supply works in the Metropolitan districts is a question that is now being prominently pressed forward by the various local authorities. Works are in operation at St. Pancras, Hampstead, and Ealing, and the Islington Vestry Works are announced to be ready for opening on March 4th. The latest local authority which has decided to undertake the duty of providing a public supply of electricity for its parishioners is the Battersea Vestry, and they have taken the novel course of offering premiums to consulting engineers and contractors for the best schemes, reports, designs, plans, and estimates, for lighting the parish, the schemes to be submitted to an engineer of eminence for an independent report. In response to the invitation, 21 schemes have been sent in and they are now under the examination of Mr. Robert Hammond, M.I.E.E., of London, who has been appointed the Vestry's electrical adviser on the subject.

---

[*] Mr. Courtney probably meant to say at speeds up to ten miles per hour.—[Ed. E.]

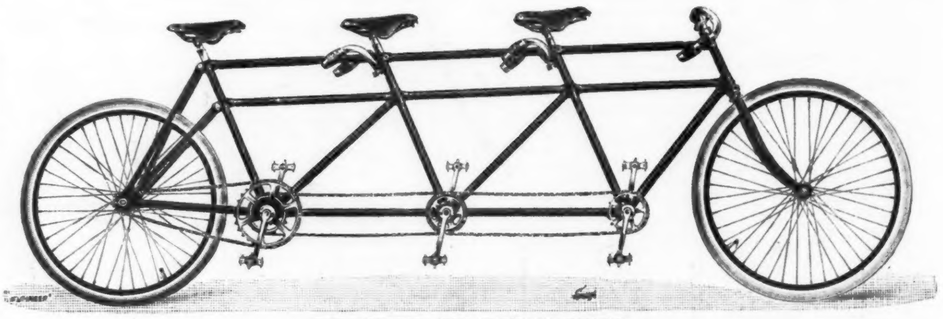
RECENT CYCLE EXHIBITIONS.

IN our impression of the 29th November we mentioned some of the cycles and cycle details as exhibited at the Stanley Club Cycle Show at Islington. This show was followed by the National Show at the Crystal Palace, and by several special shows by makers who did not exhibit at either of these. The latter include the Humber Company, as representing its Coventry, Wolverhampton, and its Beeston Works; and the Coventry Machinist Company, whose exhibition was held at the show rooms in Holborn. Several of the makers who had been important exhibitors at the National were absent this year, either by re-attendance at the Stanley or at the special exhibitions. Visitors looked in vain for any very striking novelties, but a large proportion of the machines exhibited were of better workmanship and finish. The greater uniformity in design is apparently the result of the gradual elimination of unsatisfactory detail, and the general concensus of opinion as to the superiority of the safety form of bicycle over all others.

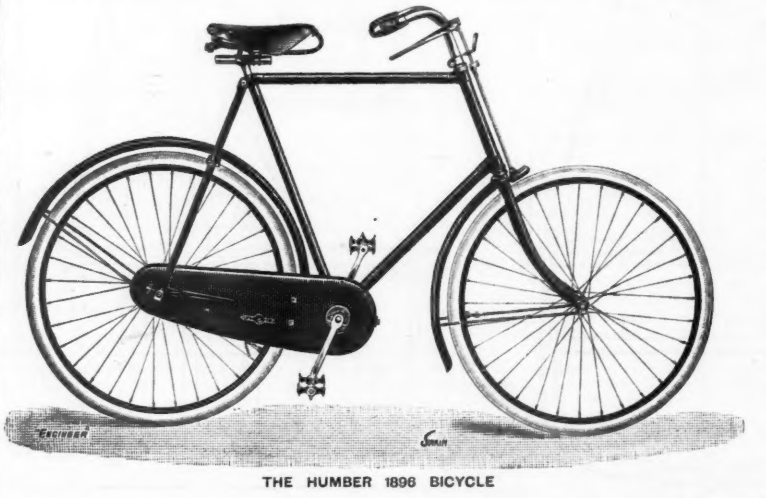


STARLEY'S "ROVER COB"

No one now exhibits any of the once general type of bicycle with the high front wheel and small back wheel, known as the "ordinary," but a few machines were shown of the front driver type, some of them having the very small front geared wheel which is used in the machine known as the "Bantam," all these front gear machines being made by the Crypto Cycle Company, and fitted with the Crypto hub gear. The Safety type, however, originated in its modern form by Messrs. J. R. Starley and Co., who, rather more than ten years ago, brought out the "Rover," is the type which, with, the modified form of frame known as the "Humber" pattern, is the favourite the world over. The Humber machines have in this respect, and in matters of detail, provided the essentials of the best designs now adopted in what one might call the consolidated pattern of the 1896 bicycle. The honours in these matters are pretty equally divided among several of those who are deservedly known as the best makers. Recent modifications do not excite much notice, although on numerous points to which the more intelligent cyclists pay particular attention, much might be said.



THE HUMBER 1896 TRIPLET BICYCLE



THE HUMBER 1896 BICYCLE

In the very large collection of machines lately exhibited one thing was particularly noticeable, the very large number of machines now made for female riders, the main difference between these and the machines for men being the absence of the top bar of the diamond frame; to make up for the absence of this important strut member, various designs of frame are adopted. One of the best patterns for the ladies' machine is that originally brought out as the "Psycho" pattern, but modified and improved in the Coventry make of the Humber machine. In this form one large curved tube forms the nearly vertical portion carrying the seat pillar and the member which grasps the head, this tube being curved downwards and receiving the crank bracket at the lower part of the curved loop. The next most satisfactory pattern is the Humber ladies' machine as made at the Beeston Works. In some of the frames for these machines, the designers' unsuccessful struggle with straight tubes to make a frame which is satisfactory from the mechanical and æsthetic points of view, is amusingly obvious, and there is room yet for improvement in design in this respect.

One of the causes of the success of the Crypto Cycle Company with the Bantam type of machine is the facility with which riders can mount the saddle while one foot still remains on the ground, and correspondingly can touch the ground with the foot when it becomes necessary to stop, this advantage being more particularly prized by those who learn to ride or continue to ride late in life. This advantage may, however, be easily secured by suitable proportion of the ordinary safety frame, and many riders have had frames made with the object of getting a low crank bracket and low seat pillar. Messrs. J. K. Starley and Co. exhibited the machine designed with this object, which we illustrate by the annexed engraving. It is known as the "Rover Cob," and enables those riders who find mounting by the step, or dismounting from it, attended by some risk, to throw the leg easily over the saddle and push off from the ground. In other respects this machine is similar to the usual pattern of "Rover," and no doubt Messrs. J. R. Starley and Co. will find this a favourite machine, more particularly for the elderly riders, so many of whom now have to learn to use a machine so as to accompany their cycle-riding youngsters. Many, however, do not require this excuse, for every year adds many hundreds, and probably many thousands, to those who late in life are finding that the bicycle provides the most enjoyable means of health-giving exercise.

At the special exhibition of cycles at the Aquarium, the Humber Company showed a number of tricycles of the rear driving pattern, and some new patterns of tandem machines, one of them from their Coventry works being an open front tandem bicycle with a ladies' seat in front. They also showed a new type of the tandem machine for three riders, as shown in the annexed engraving, machines of this class being much sought by athletic riders who like to cover great distances in a short time. The wheels of these machines are slightly heavier than those used in the single rider bicycles, and their success, and that of the pneumatic tires on which they run, affords valuable evidence as to loads that can be carried by such very light structures when well made.

The Humber roadster machine of the 1896 type is shown by the engraving below. These machines are remarkable illustrations of the evolution of a successful machine by very minute attention to the dictates of very extensive experience. Great strength is given where this is necessary, but the material is paired down to the last quarter of an ounce, where the purpose can be effected without weight. The Humber Company also exhibited a number of machines with spring frames, but without trial of this type of machine it would be unwise to express an opinion. Spring frame machines with considerable range of spring have in very small numbers been made for years, but most riders find sufficient spring movement in the saddle and pneumatic tires, and do not favour frames which need in their construction several moving parts. All the machines we have illustrated have wheels the spokes of which are of the tangent pattern; in fact, very few makers are now using the direct or radial spoke, experience having shown that the stress upon the spoke is much less severe with the larger hub flange from which the spoke is tangent.

Among the steering locks to which attention may be drawn is a very simple one used in the new Humber machine, consisting of a pin which, when inserted in the lugs on the fork collar and frame head, is fixed there by a small key carried by the user, the pin itself being also carried when the machine is in use, so as to avoid all possibility of the lock accidentally coming into action. The Premier Cycle Company still use the helical tubing for their frames, and the Raleigh Cycle Company has to some extent modified its designs, which are now very similar to those of the Humber Company. Some machines exhibited had wheels the hubs of which were exceedingly narrow between the spoke flanges, a great defect, inasmuch as the wheels either easily buckle or great stresses are thrown on the spokes by comparatively light side stresses at the tire. The Centaur Cycle Company uses for the back wheel a hub which is particularly well designed, with a view to placing the ball races at a maximum distance apart, thus reducing the pressure upon them and the balls under side stresses on the wheels and under the pull of the driving chain.

A very important part of the National Show was that in which the very numerous forms of pneumatic tires were displayed. Amongst those tires which are apparently designed with a view to novelty and freedom from infringement of the two or three leading patterns, and which have some points which recommend, are those known as the Grappler and another named the Humber. In the former the outer cover is provided with closely placed hooks very slightly raised above the surface of the material, and these very easily catch into the inwardly turned over edge of the rim, the rim not being dovetailed in form but a complete hook. The tire named the Humber has within it an aluminium ring which sits upon the edges of the outer cover, and when the inner tube is filled with air it bears upon the aluminium ring and the latter keeps the outer cover in its place.

Several noticeable forms of brakes were exhibited, amongst others of Mr. Terrell, Q.C., in which a segment of several inches in length is brought into action on the hind wheel by hydraulic pressure from a little cylinder on the handle bar, connected to a similar cylinder on the brake by means of an india-rubber tube. Erskine's brake, which acts on the rim of the front wheel and does not touch the tire, was also exhibited, and is very favourably spoken of.

The manufacturers of machine tools used by cycle manufacturers were represented on a large scale, but to these we must refer on a future occasion.

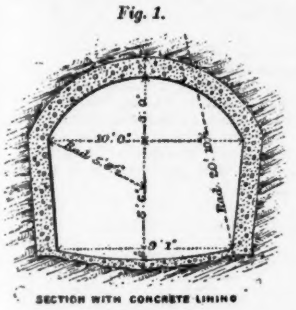
OBSERVATIONS ON THE FLOW OF WATER IN THE NEW AQUEDUCT FROM LOCH KATRINE: GLASGOW CORPORATION WATERWORKS.*

By ALEXANDER FAIRLIE BRUCE, M Inst. C.E.

THE object of the following notes is to give the results of some observations made by the author on the flow of water in the new aqueduct connecting Loch Katrine with Glasgow, with the view of determining the value of the coefficient of friction *n*, in Kutter's formula,[1] for such channels, and of ascertaining the comparative value of velocities obtained by the use of floats.

For about 53 per cent. of its length the aqueduct is lined with concrete—Fig. 1—which was built in the usual way, in 12ft. or 15ft. lengths, generally the former. Open frames of 6in. by 2in. battens were first placed in position, and ¾in. tongued and grooved boards, smeared with soft soap, nailed to them horizontally as the concrete was filled in. Every possible precaution was taken by working with spades, to obtain a good face, and except where some defects showed themselves, no rendering was afterwards necessary. The whole of the invert was concreted, and floated with a steel float, whether lining was required or not, and, as shown in Fig. 2, the unlined portions are made 2ft. wider than where lining is required in order to allow for the additional friction. This increases the available area, when the aqueduct is running full—*i.e.*, a foot above the springing level of the arch—from 64·866 square feet to 78·280 square feet, and the hydraulic mean radius from 2·869 square feet to 3·106 feet; or 21 per cent. and 8·25 per cent. respectively. These increased values were fixed upon by Mr. J. M. Gale, in designing the works, on the basis of the values of *n*, found by him experimentally for the lined and unlined portions of the old Loch Katrine aqueduct, which proved to be 0·0184 and 0·025 respectively. The part of the aqueduct selected for experiment is perfectly straight, extending from the access chamber at High Lettre to that at the Blairgar aqueduct bridge, a distance of 1921 yards. Rather more than half of it is lined, and the gradient is 1 in 5500. The depth of water flowing in the aqueduct was measured on the gauge rods in the chambers, and the true mean velocity was arrived at by dividing the quantity of water measured over the gauge weir at Mugdock reservoir[2] by the area of flow in the aqueduct. The results are given in Table I. in the Appendix.

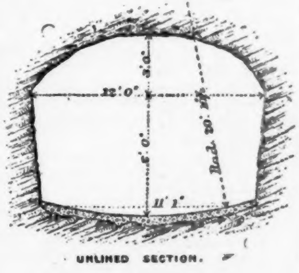
Fig. 1.



SECTION WITH CONCRETE LINING

Scale, ⅛in. to 1ft.

Fig. 2.



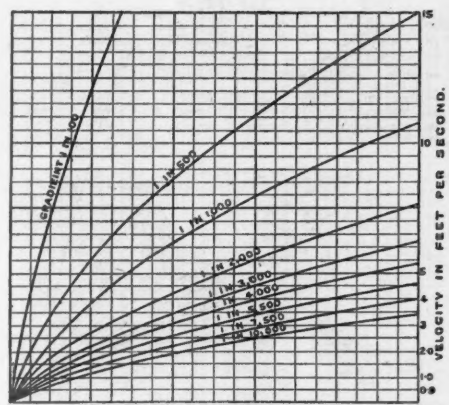
UNLINED SECTION.

Scale, ⅛in. to 1ft.

For comparison with the above experiments surface floats were used, made of circular pieces of wood 1¾in. diameter and ¾in. thick, and rod floats 1in. diameter and 2ft. 2in. long, weighted with lead, so as to be immersed to the extent of 1ft. 9½in., and painted white; hooks were screwed into the top to enable them to be more easily recovered, and each set of floats was numbered from 1 to 10. The floats were placed in the water, at intervals of between 30 seconds and 45 seconds, in the middle of the chamber, and timed as they entered the tunnel. Five or six of each series were usually between one minute and two minutes slower than the mean, owing, probably, to their having been caught and detained in eddies in the unlined portion. These were rejected, and the results given in Table I. are the means of the four or five remaining, which usually came within thirty seconds of each other.

It would appear from these experiments that velocities obtained by the use of the surface floats are, in such cases, unreliable; those in the present instance giving a result, if Darcy's formula[3] be applied to calculate the mean from the surface velocity, about 18 per cent. less than the correct figure. On the other hand, though the velocities obtained by the red floats fluctuated somewhat, they gave a mean result of only about ¾ per cent. less than the true mean, which is a sufficiently close approximation for most purposes.

Fig. 3.



The values deduced for *n* vary between 0·0119 and 0·0129, the mean being 0·0124, except in one or two cases, where, perhaps, there was some slight uncertainty in reading the quantity flowing over the gauge weir, the variation being generally only about 0·0001 on either side. This value is half-way between those given by Kutter, for "unplaned planks," and "ashlar and brickwork," and agrees with Mr. W. J. B. Clerke's figures for the aqueduct in connection with the Tansa Waterworks for the supply of Bombay.[4] The large value obtained by Mr. Gale, in his experiments on the lined portion of the old aqueduct, is no doubt due to its being lined with masonry, the joints of which are very open, all the mortar having been washed out of them. This causes the formation of eddies, thereby greatly increasing the surface friction. The velocities of discharge have been calculated for various values of *m* and *i* when $n = 0·0125$, and the velocity curves—Fig. 3—have been plotted from them.

Some observations on the discharge of the syphon pipes across the Blane Valley are given in Table II. in the Appendix. There are two lines of 48in. pipes, 3557ft. long, which, at the date of the experiments, had been laid between two and three years, and charged with water four months, so that they had been exposed to a certain amount of corrosion. The volume discharged was measured at the gauge basin, as in the case of the aqueduct experiments, and the levels of the water, both at the valve chamber where it enters the pipe, and at the basin where they deliver it again into the aqueduct, were carefully measured. The quantity delivered by the pipes for various hydraulic gradients is given in Table II., and is practically identical with that obtained by calculation, using Professor Unwin's modification of Darcy's formula, for new pipes coated with pitch;[5] viz., $v = 69 \sqrt{di}$, where *v* is the velocity of the water in feet per second, *d* the diameter of the pipe in feet, and *i* the hydraulic gradient.

In conclusion the author desires to express his indebtedness to Mr. Gale, chief engineer to the Glasgow Corporation Waterworks, for the facilities granted him for making the above experiments.

The paper is accompanied by two tracings, from which the figures have been prepared.

THE INSTITUTION OF CIVIL ENGINEERS.

THE SANITARY WORKS OF BUENOS AYRES.

AT the ordinary meeting on Tuesday, the 14th January, Sir Benjamin Baker, K.C.M.G., the President, in the chair, the paper read was on "The Sanitary Works of Buenos Ayres; Sewerage, Drainage, and Water Supply," by the Hon R. C. Parsons, M.A., M. Inst. C.E.

The city of Buenos Ayres, situated on the western shore of the Rio de la Plata, where it was 30 miles in width, was described as being built upon a bank rising abruptly to a height of 60ft. above the river. Above and below the city were extensive marshes, the soil of which was composed of running silt, whilst the bank upon which the city was constructed was of hard clay. The annual rainfall averaged 33½in., but the district was subject to violent storms, during which 4in. of rain frequently fell in one hour, the wind attaining a velocity of 100 miles. The water supply for the city, amounting to 20,000,000 gallons per day, and drawn from the river 3½ miles above the city, although very turbid, was found, when filtered, to be in every way suited for domestic purposes. For the intake in the river a shaft was sunk, about 1000 yards from the shore, communicating with a tunnel 3½ miles in length of which the first mile was under the river-bed, and which terminated at a point on the outskirts of the city, where the water was pumped into settling-ponds. These ponds, each intended for the treatment of 4,000,000 gallons per day, consisted of continuous channels, 3100ft. in length, through which the water flowed slowly, depositing during its transit a considerable quantity of the suspended alluvial matter. It then flowed on to sand filters, 2ft. in thickness, and passed downwards into covered storage reservoirs constructed beneath them. Subsequently the filtered water was pumped to a height of 162ft. into a large service reservoir in a central position in the city. This reservoir consisted of a series of wrought iron tanks, supported on cast iron columns above the surface of the ground, the whole being enclosed in a building of elaborate architectural design, faced entirely with terra-cotta manufactured in England. The author gave a detailed description of the construction of this reservoir and of the precautions adopted to prevent damage to the structure arising from the expansion and contraction of the ironwork, due to the great variations in temperature which occurred in Buenos Ayres. The tanks were arranged in three tiers, each tier supplying the corresponding zone of the city, according to their respective levels. The capacity of the entire reservoir was 15,888,000 gallons. In addition to the pressure resulting from the levels of these various tanks, arrangements were made by which the water could be pumped at a higher pressure direct into the mains whenever desirable.

The water was distributed through the city by means of five main pipes, varying between 36in. and 24in. in diameter, from which branch pipes passed to each separate block of houses. A uniform arrangement of piping was repeated throughout the city, and a definite position assigned to each valve and hydrant. The internal services of both water supply and drainage were carried out in such a manner as to fulfil modern sanitary requirements.

The sewering of the town was on the combined principle, the collecting sewers being capable of discharging a rainfall of 1½in. per hour, which had been found amply sufficient to carry away the rain which fell during the heaviest storms. The sewers were ventilated by a pipe carried up the front of each house to a height of 6ft. above the roof. This pipe was connected with the branch sewer immediately outside the syphon-trap which cut off the sewer gas from the house. Air was admitted into the sewers by the gratings of the street manholes. The area of the city was divided into separate drainage districts, in each of which the collecting sewers formed an independent system converging to the lowest point, and there communicating with the intercepting sewers. The capacity of these latter was sufficient to carry off a rainfall of ¼in. in twenty-four hours, the difference between this quantity and that conveyed by the collecting sewers during storms being removed by large conduits discharging directly into the river in front of the city. The sewage passed from the collecting sewers of each district to the intercepting sewer over a trough, the capacity of which was limited to the quantity to be conveyed by the latter, so that any larger quantity was forced to overflow into the storm-water conduits. The capacity of these troughs was regulated by means of a valve, and corresponded in each case with the discharge from the district, so that the quantity of storm-water conveyed to the pumping-station was reduced to a minimum. The conduits were for the most part 14ft. wide by 12ft. high, and the total quantity of water conveyed by them was about 9000 cubic feet per second. Over the greater area of the town the sewage found its way by gravitation into the intercepting sewers, pumping being resorted to only for the low districts near the river. In two of the smaller districts the sewage was lifted by steam pumps; but in the large one lying to the south of the city an entirely different method was adopted, consisting of short pipe sewers, 6in. and 9in. in diameter, laid in shallow trenches, the rain water being entirely excluded from them. Over this area the sewage was raised at seventeen points by means of small pumps actuated by hydraulic motors worked automatically from one central power station. The pressure employed was 750 lb. per square inch in the accumulator, and the pressure water was distributed to the motors through about eight miles of hydraulic-pressure piping varying between 6in. and 3in. in diameter. The pumps, which were in duplicate, were placed in wells sunk beneath the roadway, and were started and stopped automatically by floats actuated by the rise and fall of the sewage. The pressure-water was admitted into a ram placed in the centre of the plunger, the return stroke being performed by two small push-back rams, constantly open to the hydraulic pressure. The pumps were 30in. in diameter, some being of 3ft. and others of 4ft. stroke. The area provided for in this portion of the scheme was about 1600 acres, and the ultimate population 200,000. In this district automatic self-closing manhole covers were adopted to exclude the floods, which frequently inundated it. Self-acting valves were provided for flushing the sewers by water supplied from the mains.

The sewage was discharged into the river twelve miles below the city at a point where no trouble was caused by its being washed back. The outfall conduit on leaving the city passed beneath a tributary of the Rio de la Plata, 200ft. in width, by an inverted syphon, consisting of three tubes of cast iron 5ft. high by 2ft. 3in. wide, embedded in concrete and supported on cylinder foundations sunk into the bed of the river. To avoid obstructing the river during construction, these tubes were put together inside large horizontal cylinders of wrought iron, which, after being built on shore, were floated out and sunk into position. The space between the casing and the tubes was then filled with concrete, in which were embedded strong wrought iron lattice girders with the object of giving sufficient strength to span the intervals of 50ft. separating the cylinder foundations, and thus rendering the tubes independent of any support from the soft mud upon which they rested. The abutments of the syphon were also upon cylinder foundations, the body of the abutment being constructed within an annular cofferdam of 14in. piling. As no solid foundations could be obtained for this work, reliance had to be placed upon the depth to which the cylinder foundations were sunk into the soft material of the river-bed. To secure the fall necessary for discharging the sewage at the outfall, a pumping station was erected on the line of the conduit where the whole sewage was lifted a height of 43ft.

The paper was accompanied by tables of the daily consumption of water for the last twenty-one years, and also of the comparative death-rates for the years preceding and of those following the inauguration of the sewerage works, which afforded conclusive evidence that the annual death-rate of the city had been reduced from 32 to 24 per 1000. Details of the cost of the works were given, and showed that about 2½ millions sterling had been expended on the water supply, and 3 millions sterling on the sewerage and drainage, equivalent to £5 10s. and £6 respectively per head of population served. There was also appended a brief account of the political and financial vicissitudes to which the works had been subject since their inception in 1871, which prevented them from being completed until twenty years after their commencement.

THE objects and work of the Electrical Standardising and Training Institution are explained in the *Faraday House Journal* of this month, which includes articles on bitumen conduits, electric light engines at Newport electric welding, and on a Ferranti slow-speed alternator.

AMERICAN ARMOUR PLATES

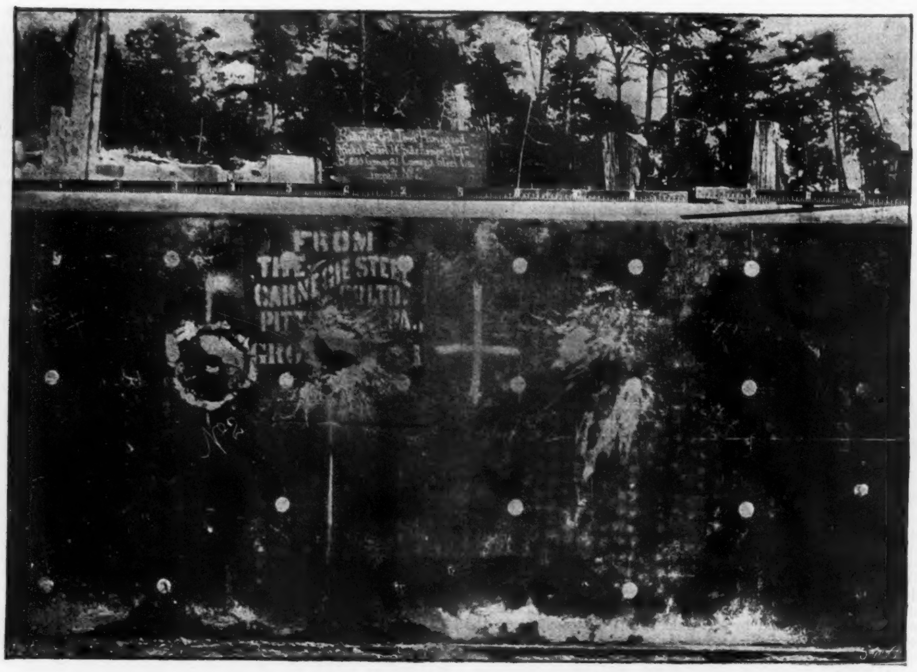

Fig. 1—CARNEGIE DOUBLE FORGED HARVEY 14in. PLATE

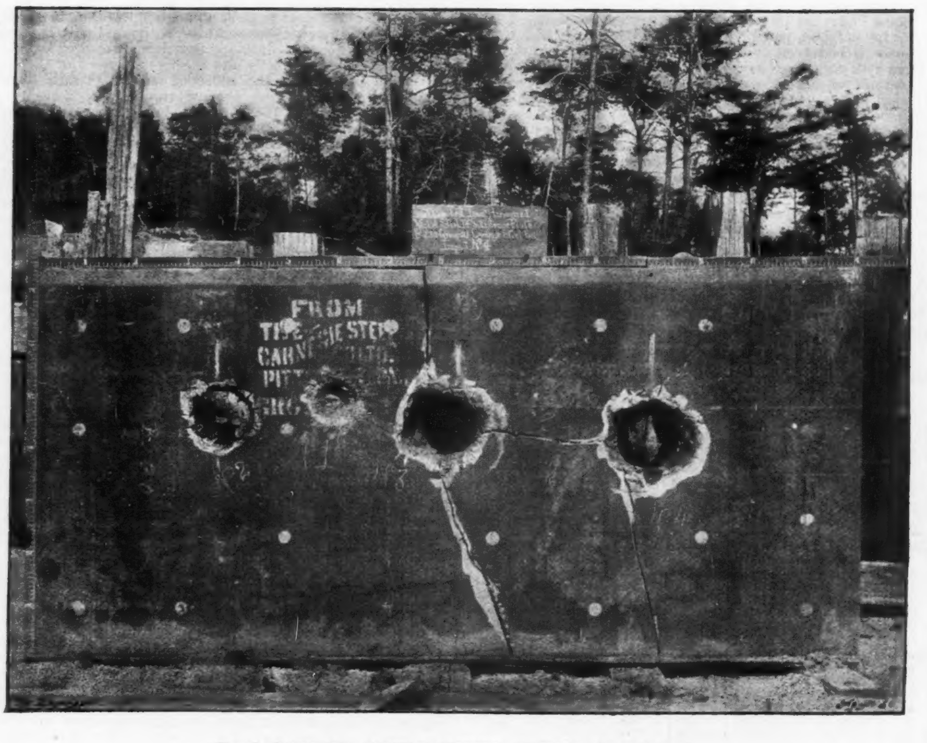

Fig. 2—CARNEGIE DOUBLE FORGED HARVEY 14in. PLATE

DOUBLE FORGED CARNEGIE ARMOUR.

In a paper read before the United Service Institution, Captain Jaques gave the details of a trial of a double forged 14in. plate made by the Carnegie Company. We have now received copies of the four official photographs of this trial. Two of these, however, are sufficient to illustrate the account, one—Fig. 1—being taken before the plate began to crack, and the other—Fig. 2—at the end of the trial. We think it best to give Captain Jaques's account just as it stands, adding a few remarks at the conclusion.

"Ballistic Test of Iowa's Side Armour-Plate.

"On September 4th, 1895, at Indian Head, Md., the Iowa's 14in. side armour ballistic plate was tested. The plate was mounted on backing, and a structure representing a section of the ship's side. The 10in. breech-loading rifle, with Carpenter armour-piercing shell, weighing 500 lb. each were used in the test.

"The left-hand end of the plate as mounted was the bottom end with reference to the ingot. The first point of impact was taken at a point about 10in. above the line of the bevel, and about 2ft. to the left of the middle of the plate. The shots were fired through the screens; the striking velocity as measured was 1482 foot-seconds, the contract velocity being 1472 foot-seconds. The shell broke up on the plate, leaving the point embedded in the face of the plate to a depth of about 3½in.; there were no cracks. The second point of impact was taken about 8in. above the bevel line, and 29in. to the left of the first point of impact. This distance should have been 35in., but as the plate showed no disposition to crack the shot was placed nearer. The velocity on this round was 1856 foot-seconds, the contract velocity being 1859 foot-seconds. The shell broke, leaving the ogival, much distorted, buried to a depth of about 9in. in the plate. There were no cracks. The plate thus passed the contract test with a large margin to spare.

"The third round was fired with the 12in. breech-loading rifle. A Wheeler-Sterling shell, weighing 850 lb., with a striking velocity of 1800 foot-seconds, was used. The point of impact was taken about 30in. to the right of the first point of impact, and about 8in. above the bevel line. The shell broke across the forward part of the body, about two-thirds of the body of the shell being found in one piece in front of the target. The point of the shell penetrated to about the back of the plate, which was cracked across from top to bottom through this impact.

"As the contract velocity for the second shot against a 17in. Harvey plate is 1858 foot-seconds, and as the additional 58ft. would not have caused this shell, although a very good one, to have perforated the plate and backing, it appears that this plate, after having stood the test of a 14in. plate, has passed the test of a 17in. plate. This is a better record than any other thick plate heretofore tested. The 14in. re-forged plate, tested in February last, was perforated by a Wheeler-Sterling shell with 1858 foot-seconds, although it kept out a Carpenter 12in. a.p. shell with the same velocity. This plate, therefore, although a bevelled one, stood a better test than the 14in. experimental re-forged plate of last February.

"A fourth round was fired at this plate later, the point of impact being taken on the right-hand portion. A Wheeler-Sterling 13in. a.p. shell weighing 1100 lb. was fired with a striking velocity of 1800 foot-seconds. The shell perforated the plate, backing, and structure, and was recovered unbroken. The plate was cracked comparatively little."

The excellent resistance of this plate will be better understood if we recall that the second, or higher velocity shot, for an 18in. Harvey plate, with the 13in. gun, requires a velocity of 1810 foot-seconds.

These tests justify the conclusion that the forging after carbonisation, as practised by the Carnegie Company, benefits very materially the body of the plate, while at the same time it does not appear to impair the efficiency of the carbonised surface.

That Captain Jaques' remarks are justified we think the following figures will show. The calculated perforations through iron due to each of these rounds are shown in the table below:—

	Projectile.		Striking velocity.	Perforation.		
				Iron.		Steel.
	Calibre.	Weight.		Maitland or Fairbairn.	Tresidder.	Tresidder.
	inches.	lb.	f.s.	inches.	inches.	inches.
Round 1 ..	10	500	1482	16·0	15·4	12·3
Round 2 ..	10	500	1856	20·4	21·6	17·3
Round 3 ..	12	850	1800	23·5	24·4	19·5
Round 4 ..	13	1100	1800	25·8	26·7	21·4

This 14in. plate then defeated, without cracking, two projectiles, the calculated perforation of the second being 17·3in. of steel untreated. It kept out but broke under the third with 19·5in. calculated perforation. The last round outmatched it. This for a plate of this great thickness is a great feat. We especially lay stress on the thickness, because we have before said thin plates have still greater resisting power, a first-rate 6in. double-forged plate keeping out a 6in. projectile.

The official particulars are as follows:—Fig. 1, official number 424. Ballistic test of Iowa's 14in. double forged face-hardened side armour plate, B-230, group No. 21; the Carnegie Steel Company. Impact No. 2: Striking velocity, 1856 foot-seconds; striking energy, 11,954 foot-tons. Carpenter 10in. A. P. shell, lot No. 11, penetrated about 11in. and broke up; no cracks in plate. Effect on target structure very slight.

Fig. 2, official number 426. Ballistic test of Iowa's 14in. double forged face-hardened side armour plate, B-230, group No. 21; the Carnegie Steel Company; mounted on experimental target structure, representing framing behind the belt armour of the Iowa. Impact No. 4: Wheeler-Sterling 13in. A. P. shell, lot No. 2. Striking velocity, 1800 foot-seconds; striking energy, 24,736 foot-tons; penetration, through plate, backing, framing, target structure, and into sand of butt. Projectile recovered entire.

TEST OF A STEAM ENGINE.

It will be remembered that some time ago we illustrated an engine constructed for Sir Titus Salt, Bart., Sons, and Co., by Messrs. Cole, Marchent, and Morley, Prospect Foundry, Bradford. Since these engines were made the firm have constructed another exactly similar, which has recently been tested by the National Boiler Insurance Company. Below we give the results of the test, which we consider to be very good. Boiler, 30ft. long by 8ft. diameter, having total heating surface of 965 square feet, and a grate surface of 38 square feet; a Green's economiser of 1440 square feet area of heating surface. Engine, high-pressure $15\frac{17}{32}$in., low-pressure $32\frac{3}{32}$in., stroke 3ft. 6in.; cylinder ratio 1 to 4·5. There is a horizontal air pump 11in. diameter of the same stroke as the engine; the ratio of the air pump bucket displacement to low-pressure displacement, 1 to 8·6.

The test was made on November 19th, 1895, with a flying start and a flying finish. The duration of the test was three and a-half hours in the morning and three and a-half hours in the afternoon:—

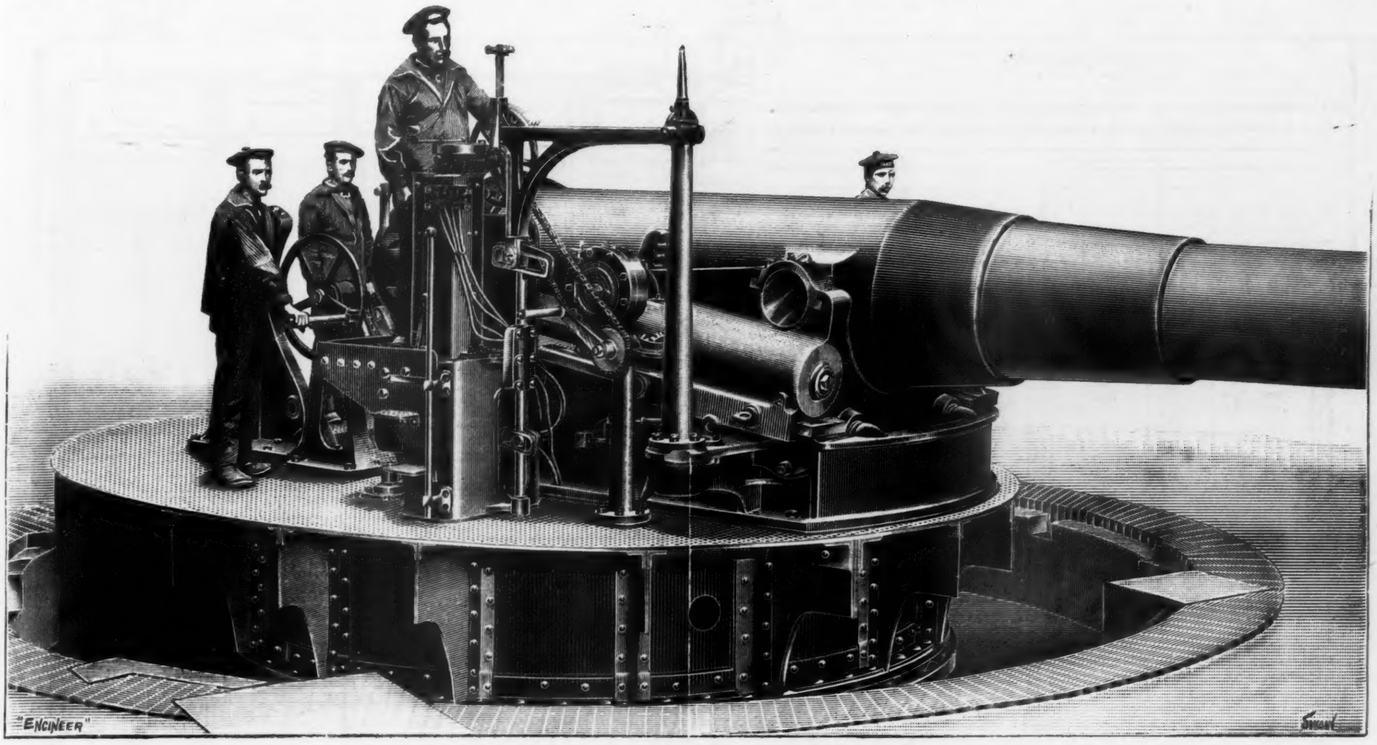
Mean revolutions per minute	83·4
Mean boiler pressure above atmosphere	137
Atmospheric pressure	14·5
Vacuum in condenser, per gauge	12 lb.
Vacuum in low.pressure cylinder, per indicator	10·8 lb.
Mean temperature of injection water	71 deg.
Mean temperature of hot well water	106·5 deg.
Mean temperature of feed to economiser	107 deg.
Mean temperature of feed to boiler	254 deg.
Mean total indicated horse-power	344·6
Mean weight of steam used per indicated horse-power per hour	14·25
Evaporation of water per pound of coal	9·18
Evaporation of water from and at 212 deg.	10·6
Weight of coal per indicated horse-power per hour ..	1·55
Weight of coal per square foot of grate per hour, in lb.	17

The insurance company report as follows:—"Throughout the test the running of the engine was highly satisfactory." The figures given above are the mean of the morning and afternoon test.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet Engineer: Richard S. Hamm, to the Endymion. Staff Engineer: Richard G. Willby, to the Northampton. Chief Engineer: Edwin C. Carnt, to the President, additional, for service at the Admiralty. Engineers: Wm. H. Wood, to the Victory, additional, as assistant to chief engineer in charge of drawing-office, Portsmouth; Arthur R. Grant, to the Pembroke, and Ernest Haves, to the Victory. Assistant Engineers: Walter Stokes, to the Majestic; Henry M. S. Tuckwell, to the Repulse; and Percival R. T. Brown and William P. C. Spriddle, to the Endymion. Mr. E. Carnt, chief engineer, who has been employed for some time in the chief engineer's office in the dockyard, having been transferred to the Admiralty, his place in the yard has been taken by Mr. Wm. N. Wood, engineer, serving in the Majestic.

Electric Lighting of Stone Quarries.—Electric lighting for outside industrial concerns has not up to the present made any great headway, but a noteworthy application of the modern illuminant is that just carried out at the Ballochmyle Stone Quarries, Ayrshire. Owing to the amount of work on hand, and the large demand for stone which he found himself totally unable to supply during the hours of daylight, the lessee of the above quarries, Mr. Bain, decided to introduce the electric light. The order for plant and machinery was placed with Messrs. Paterson and Cooper, of London and Glasgow, and the installation has been successfully completed under the superintendence of Mr. E. George Tidd, M.I.E.E. The area at present being worked is the largest that has ever been operated upon since these quarries were opened. Five powerful steam cranes are kept constantly at work, raising to the bank large blocks of red sandstone, and, that the work may proceed night and day, six arc lamps, each giving a light equivalent to 2000 candles, have been hung over the workings. The light is thrown down into the farthest depths of the quarries—in some places 200ft.—enabling work to go on uninterruptedly.

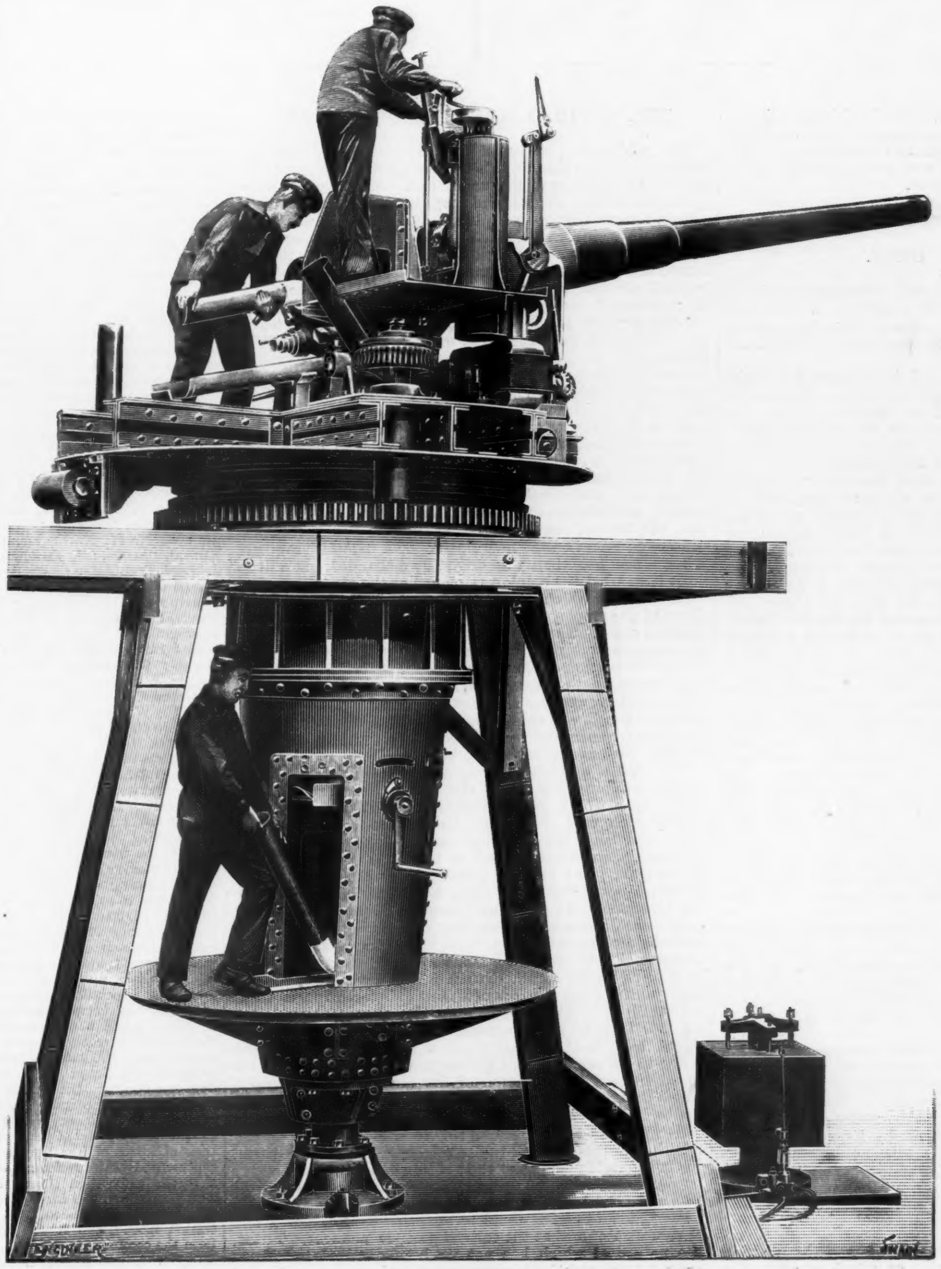
CANET ELECTRIC TURRETS FOR THE DANISH WARSHIP SKJOLD



CANET ELECTRIC TURRETS.

We may say in introducing the following brief description of the newest patterns of Canet electric worked turrets, which we have obtained from the manufacturers, that the general principles said to characterise the working of French turrets are alternative hand gear, the provision of automatic return of all lever handles to their original place directly they are released, by means of counterweights; and the provision of safety gear, so as to guard against all mistakes and accidents as far as possible in action. In the hydraulic working the rotation of the turret is generally effected by a simple application of chains and hydraulic cylinders. It may be seen that the same general principles are kept in view in the electric system of Canet, in which the French Government has taken the lead of England. Our own Powerful and Terrible have barbette mountings for 9·2in. guns worked by electricity, which appear to be excellent, but the ships will not be in commission for some time to come.

The Société des Forges et Chantiers de la Méditerranée have turned out or have now in progress nearly forty turrets worked by electricity for the Latouche-Tréville, the Jaure'-guiberry, the d'Entrecasteaux, the Pothuau, the St. Louis, the Captain Prat, the Skjold, and the Carlos V. Those last completed, which have embodied in them the newest improvements, are for the Danish coast defence ship Skjold. The work supplied includes (1) one Canet turret for a 24 cm. gun, (2) three Canet turrets for 12 cm. guns. These are closed turrets, and, as in all others of the same type, the electric gear is supplemented by alternative hand gear, with provision for instantly changing by means of switches from one system to the other. In the 24 cm. gun turret electric working is applied to laying the gun and also to raising the ammunition. In the 12 cm. turrets it is applied only to laying the gun. In the latter, hand gear provides such efficiency and speed that there is no necessity for having recourse to an electric motor.



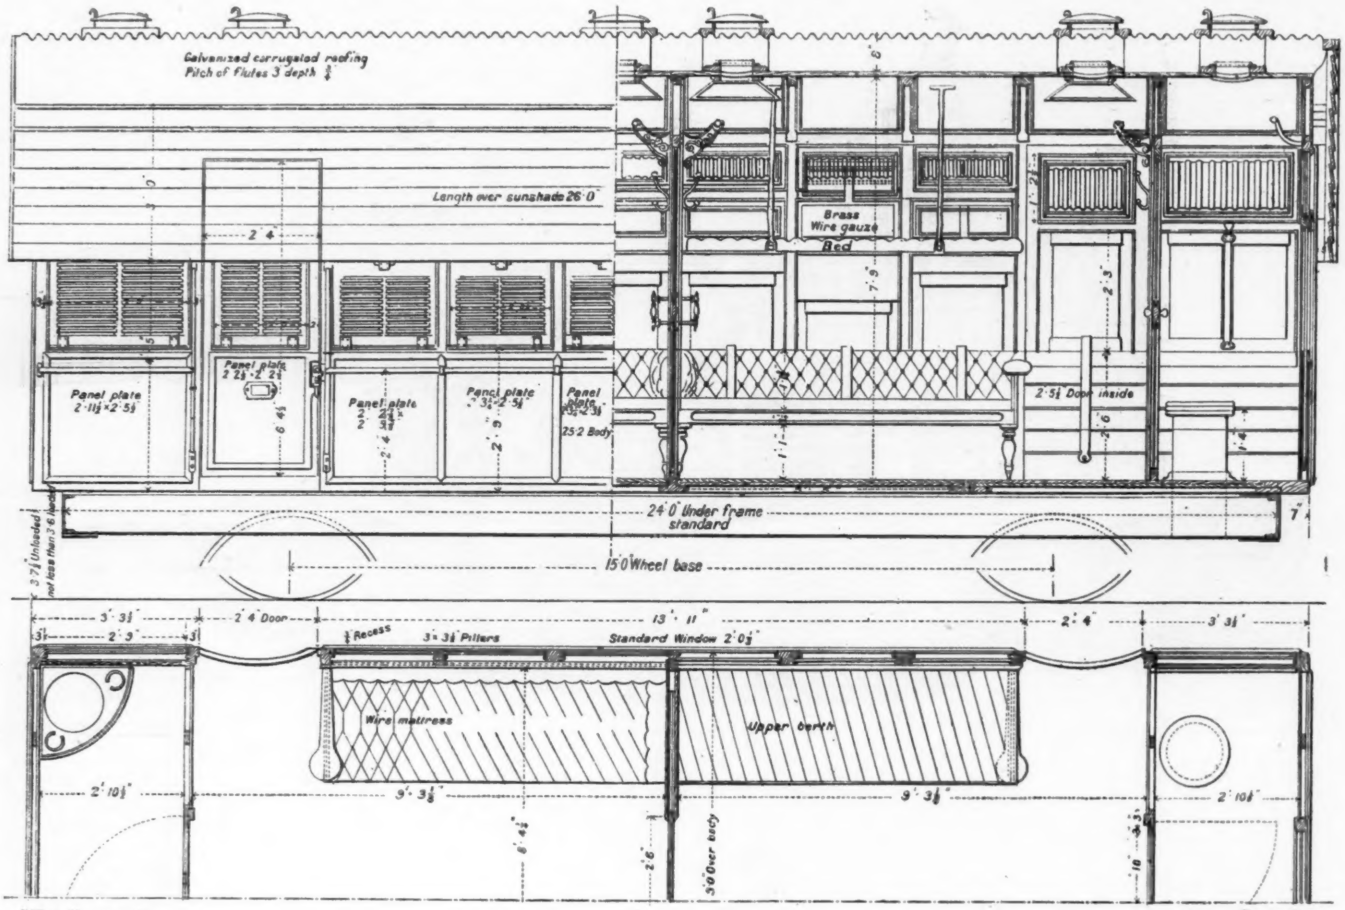
The electric apparatus for laying the gun is of the type known as the "cartouche électrique type." Excellent results, we are told, were obtained with this system on the Latouche-Tréville, and these have been entirely confirmed by trials which took place at Havre in the presence of the Danish Commission, and which have given prominence again to the great accuracy with which laying can be performed by the use of the "cartouche électrique," identified with the names Canet, Hillairet, and Hugnet. Not only has the captain of the gun complete control throughout, whatever may be the velocity of rotation of the turret, so that he can stop it dead, but also in laying he can at will, in either direction, make corrections less than the fortieth of a degree. These trials have been repeated many times before a great number of officers.

Thanks to the special arrangements which characterise the Canet turret system, and to the adjustment of weight, the work necessary to give rotation to the running weight is reduced to a minimum. Thus for the motor for rotation of the turret of the 24 cm. gun, the nominal power is 15-horse power, and hardly two-thirds of this amount is ordinarily required. For the rotation of the turret of the 12 cm. gun a motor of 3-horse power is sufficient.

The ammunition hoist of the 24 cm. gun turret is worked by a motor of 8-horse power. It is controlled by a commutator of a special kind, provided with automatic return to either end of its range, and with special safety arrangements to prevent the possibility of accident.

The engravings show the general arrangements of the turrets. No attempt is here made to give a lengthened description in detail. A report on these turrets has been made at the request of M. Neilson, formerly director of construction, and now director of the dockyards of Bur-

CONTRACTS OPEN—FIRST-CLASS CARRIAGES, OUDE AND ROHILKUND RAILWAY



"THE ENGINEER" SWAIN ENG

meister and Wain at Copenhagen. The Danish Commission entrusted with the testing and acceptance trials at Havre consisted of MM. Schwanenflügel and Rasmutten. The President of the French Republic was present at the trials, and himself worked the 24 cm. turret.

CONTRACTS OPEN.

THE illustration shows the general arrangement of the first-class carriages for which the Secretary of State for India in Council is now—amongst other rolling stock—asking tenders, and are intended to run on the Oudh and Rohilkund Railway.

The carriage is 25ft. 2in. long, and to accommodate eight passengers with a bed each. A partition with a sliding door shuts off one half of the carriage from the other. There is a lavatory and a water-closet at each end, also a looking-glass, 18in. by 18in., set in teak frames. There is a liberal allowance of light, and of hat pegs and light luggage racks. The roof is double, consisting of an inner wooden roof and an outer one of corrugated iron, with an air space of 8in. between the two. There is a wooden sunshade running all round the carriage, extending 3ft. downwards from the corrugated iron roof, thus leaving a free air current space from side to side of the carriage. The top bed frame is made of wrought iron piping, with solid gun-metal corners, brackets, and washers; the ends of the corner pieces turned to fit the piping, and secured by ½in. rivets. All the ironwork for the bed fittings not turned or otherwise fitted must be filed up to a smooth surface, and then black japanned. One side of the bed is attached to the carriage by brass hinges, and the other side, when let down for use, is suspended from the roof by chains encased in leather. The lavatory fittings are to be of the best gun-metal, ground perfectly tight, the ends fitted with union screws. The piping is to be the best wrought iron, with bends and unions to match. The wash basins are of cast iron, with gun-metal union screw and plug with chain. The flanges, top and interior of the basins, and all the front flange or bead, are to be enamelled white with the best glass enamel; the exterior is to be glass enamelled grey. The commodes are to be of wrought iron, No. 14 B.W.G. thick, and provided with a French-polished teak lid, 1in. in thickness. The steel wire mattresses for the carriage seats are to be of the best quality and finish, made by the Longford Wire, Iron and Steel Company.

The roof sheets are to weigh, before galvanising, 1¾ lb. per square foot, and after galvanising 30 oz. per square foot. These sheets are to be corrugated to a pitch of 3in., and ¾in. deep, after they are galvanised. After the sheets are finished they are to be stacked in the contractor's premises for a month before they are inspected; the sheets must also be perfectly free from spangle.

Every delivery is to consist of the ironwork and other materials complete for a given number of vehicles. No delivery of incomplete parts will be accepted. The name of every maker from whom it is proposed to obtain any of the materials to be submitted to the consulting engineer for approval before the work is commenced. Every piece of iron or steel must be interchangeable without dressing of any kind. Tests, specifications, and conditions are all as usual. Tenders to be in by 28th inst.

AT the last meeting of the Civil and Mechanical Engineers' Society, a paper was read on "Lock-nuts and Nut-locking Devices," by Mr. E. H. G. Brewster, A.M.I.C.E.

THE CLYDE ENGINEERING DISPUTE.

THE engineering wages dispute on the Clyde and at Belfast, although thrown into the background somewhat by the "excursions and alarums," and warlike sensations sprung on us from abroad, still drags its weary length, without, on the one side or the other, any definite indications of terminating. Mr. Sellicks, the president of the Associated Society of Engineers, has returned to London, and the informal and private negotiations carried on during his sojourn in the Clyde district have been continued since. The game of "see-saw," however, has been kept up in respect of rumoured "near prospects of a settlement," followed closely by "no progress has been made towards an arrangement of differences." It is at least safe to infer that one result of Mr. Sellick's visit was to show the executive of the men's society the hopelessness of expecting the employers to take the initiative in any proposed modification of their offer made at the Glasgow conference.

Some informal proposals, emanating from the men's side, made since Mr. Sellick's visit, go to show that a disposition has set in amongst them—or has for some time existed, though not openly declared—to fall away from the "no surrender" attitude and spirit so long maintained. Lord Provost Bell, of Glasgow, has been the intermediary in these half-hearted advances on the men's part. The modified overture is for much less than was originally demanded, but a little more than what the employers offered at the conference, and for an advance which should take effect at once. The disposition of the employers on this issue has, so far, been of the negative order. The date fixed by them for the concession of the advance was arranged with a view to the completion of the major portion of the work which had been undertaken at a low contract price, and the intervening period they estimated at eight weeks. This contract work has not since been advanced much, and the employers now are disposed to postpone any advance that may be decided on until the intention of their original stipulation has been met.

This, and a number of other stubborn circumstances, at present combine to persuade the men of the futility of any longer maintaining an uncompromising attitude. It is being clearly recognised that while the apprentices continue at work, and have the assistance of the few men who have returned, the masters will not be forced to concede further. Then, again, great pressure is being put upon the engineers by the shipyard workers to effect a settlement, as otherwise the associated industries must come to a complete standstill very soon. Practical illustrations are not wanting to show that the prolonged deadlock is having injurious effects on the securing of fresh orders. Instances of orders being postponed or of being placed elsewhere than on the Clyde, owing to the uncertainty of delivery, are of almost daily occurrence. Well-known Clyde builders entirely lost the chance of tendering for four torpedo boat destroyers, which but for the strike might have been secured; and a strong fear exists that owing to the same cause, Clyde firms who might be expected to secure a fair proportion of the ten third-class cruisers which the Admiralty has just arranged to contract for, will not be in a position to tender, more particularly as speedy delivery is said to be a leading condition in the tenders.

Although there is still the usual uncertainty about them, the latest statements as to the position of affairs wear a very hopeful aspect. Through their intermediaries, Lord Provost Bell and Lord James, both sides, it is said, are quietly making arrangements to bring about an amicable understanding and have work resumed at the earliest possible moment. Terms, the nature of which has not yet been divulged, have been arranged and practically agreed upon by both employers and employed, though there yet remains some little difference of opinion as to when the advance is to come into force. Matters, apparently, being now so well in train for settlement as regards the amount of the advance, the hope may be expressed that the employers will not insist upon adhering to an uncompromising, though perhaps justifiable, position as regards the date at which such advance shall take effect. Yesterday a joint meeting of the employers on the North-East Coast and those of the Clyde and Belfast was held at Carlisle, but whether the business considered had direct reference to the present position of the dispute or not is uncertain.

THE DELEGATES OF THE IRON AND STEEL TRADES, who, under the auspices of the British Iron Trade Association in the summer visited various German and Belgian works in order to inquire into the subject of foreign competition, have at last agreed upon their report, and this interesting document will be issued in a few days.

ASSOCIATION OF WATERWORKS ENGINEERS.—At the Exchange Hall, Nottingham, on Saturday afternoon, a meeting was held for the purpose of taking into consideration the advisability of forming a British Association of Water Engineers. The chair was taken by Alderman Sands, and on his left the Sheriff—Mr. J. Wright. Those present were Mr. D. M. F. Gaskin, engineer (Nottingham Waterworks); Messrs. R. H. Swindlehurst, Bolton; H. Roberts, Ipswich; T. A. Simpson, Kettering; A. F. Bowker, Mid-Kent; W. G. Pierce, Richmond; A. F. Bryant, *Journal of Gas Lighting*, &c.; S. Moore, Nottingham; C. H. W. Biggs, London; H. J. Kilford, Ilkeston; J. Radcliffe, Todmorden; W. Watts, Oldham; J. Lees, Tonbridge; E. Sandeman, Plymouth; T. W. Dent, *Bradford Observer*; H. Ashton Hill, South Staffordshire; E. A. B. Woodward, Wolverhampton; W. Matthews, Southampton; H. C. Marks, Dewsbury; R. O. Wynne Roberts, Oswestry; E. W. Dixon, Harrogate; E. Sainty, Eton; T. V. Ritson, Kendal; W. Millhouse, Scarborough; J. B. Fenwick, Retford; T. L. Hughes, Wigan; R. Kennedy, Kilmarnock; W. J. Wane, Maidstone; I. Carr, Widnes; T. Raynes, Birmingham; J. Deas, Warrington; A. Graham, Mansfield; C. H. Priestley, Cardiff; H. W. Pearson, Bristol; W. Terrey, Sheffield; W. A. Richardson, Birkenhead. The town clerk, who was unavoidably absent, was represented by Mr. F. B. Harris. In opening the proceedings Alderman Sands said it was singularly appropriate that the first meeting should be held in Nottingham, because the town was the birthplace of one of the first engineers whose attention was directed to waterworks and water undertakings generally, and he might now be looked upon as one of the fathers of works of that nature—Mr. T. Hawksley. Mr. Gaskin, who was received most cordially, remarked that he thought the inauguration of such an institution would benefit not only themselves, but also the consumers and the public generally. As the meeting was aware, they were at present an isolated body—that was to say, as compared with other bodies, such as gas and electrical engineers. He would like to make himself clearly understood that they were not departing from the parent institution in Great George-street. It was one of the finest in the world, but the meeting would know that the association in Great George-street could not take up in detail many questions with which the proposed new association wished to deal. For instance, the diversity of regulations between different towns. He was convinced that combined action would effectually dispose of the inconvenience. He thought a strong argument in favour of the formation of an association of the nature contemplated was the issue, a month or so ago by the Board of Trade, of a circular having reference to domestic boilers. Mr. Gaskin proposed—at the suggestion of Mr. Biggs—that an institution to be called the British Association of Waterworks Engineers should be formed, and the first members should be composed of those present, and those who had signified their attention of becoming active supporters. Those gentlemen represented waterworks all over the country. It was proposed that the association should consist of members and associates. This proposition was carried, and at the suggestion of Mr. Gaskin, Mr. Macintyre, London, was elected provisional secretary. Mr. Gaskin moved, and it was agreed, that the following gentlemen form the committee:—Messrs. J. Parry, A. F. Bowker, N. Ashton Hill, W. A. Richardson, I. Carr, C. H. Priestley, W. Matthews, H. Roberts, E. A. B. Woodward, W. Terrey, W. Watts, and W. Leggatt.

RAILWAY MATTERS.

In addition to orders for locomotives recently announced as having been placed with Glasgow houses, it may be stated that Messrs. Sharp, Stewart, and Co., Atlas Works, Springburn, have secured an order to build seven powerful passenger engines for the Midland Railway.

A tramcar dining car is the latest innovation proposed by an enterprising Brooklyn caterer, who thus proposes to furnish a good breakfast to men going early to business. He would also serve a luncheon to shoppers in the daytime and dinners to theatre parties in the evening.

Some new Post-office cars on the Erie Railway are 65ft. in length, and are carried on two six-wheeled bogies, each with a wheel base of 10ft. 6in. The width of the cars is 9ft. 8⅜in. over the sills. They are lighted by eleven Pintsch gas lamps supplied by four gas reservoirs 8ft. 6in. long, and 20in. diameter.

A colossal group representing engineering, which is to surmount and adorn the central gable of the new Bombay, Baroda and Central India Railway offices in Bombay, now being erected from the designs and under the supervision of Mr. F. W. Stevens, C.I.E., F.R.I.B.A., is the work of Mr. E. Roscoe Mullins, sculptor, of London, who has been commissioned to execute it in Bath stone. The *Indian Engineer* says, Mr. Mullins has also instructions to execute large medallion heads of the late Colonel French and General Kennedy, the pioneers of this railway, to be placed in the circular panels over the outer arches of the central carriage porch of this building.

In mentioning methods of making joints with locomotive fire-box crown stays, the *Railroad Gazette* remarks concerning stays with a washer placed under the head, that when this was first tried copper washers were employed; but this metal has been abandoned, unless the road ordering the locomotive specifies copper washers. The reason for discontinuing the use of copper washers is that they do not last. Either a galvanic action takes place which destroys the washer or they do not stand the heat. In the place of copper charcoal, iron has been substituted, and it is the present practice of the builders to use this style of washer on their latest engines.

Reports from the car building companies of the United States show that car building has taken an upward turn, the output of the contracting shops being 31,893 freight cars. This is in comparison with 17,029 freight cars built in 1894. When we say that car building has taken an upward turn, we limit the phrase to a comparison with the previous year. The total of cars built this year is not a large record by any means, and makes the number built in the years immediately preceding—51,000 in 1893 and 93,000 in 1892—appear extraordinarily large. It seems probable that railroad managers have continued the use of much equipment, not in good condition, and which ordinarily would be replaced. In this fact lies the hope of the car builders.

In addition to the very extensive terminal arrangements for goods and coal already possessed by the Midland Railway Company at St. Pancras, Somer's Town, and Kentish Town, the company now finds it necessary to increase its coal depôt at Somer's Town by about six acres, having more wagon accommodation than at any existing depôt. Already large blocks of once important but recently neglected houses have been removed, and new blocks of model dwellings have been erected to provide for those who will be displaced by the removal of houses to make room for the new depôt. Messrs. Howell and Co., Westminster, are the contractors for the new buildings and depôt works, which will be erected from the plans prepared under the chief engineer of the Midland, Mr. J. A. M. McDonald, M. Inst. C.E.

The Secretary of State for Foreign Affairs has received from her Majesty's Minister at the Hague an extract from the *Staatscourant* of the 4th inst., announcing that the Technical Office of the Colonial Department at The Hague will receive up to noon on the 22nd inst. tenders for 16 bridges and 18 turntables for the State railways in Java, and also for iron plates for the Marine Department of the Netherland Indies. Full particulars can be obtained of Martinus Nijhoff, 18, Nobelstraat, The Hague, on payment of 50 cents (10d.), 1 florin (1s. 8d.), and 50 cents (10d.) respectively. It is also announced that the Intendant of the 1st Division of Infantry will up to noon of the 22nd inst. receive at 106, Breadstraat, The Hague, tenders for 90,000 kilos. of hard wheat, and for 30,000 kilos. of soft wheat. Full particulars may be obtained from Gebroeders van Cleef, The Hague, on payment of 10 cents (2d.).

All of the thirteen locomotive building companies in the United States, except one, built more locometives in 1895 than in 1894, and the total number of engines built foots up 1109, against 695 in the previous year. This is something of an increase, and a very good record so far as it goes, but that it does not represent a normal increase seems evident from the number of engines built in the five previous years, when never less than 2000 locomotives were built in any one year. That this is a safe deduction the large orders for locomotives which have been placed in recent weeks give additional evidence. Two of the companies reporting locomotives built in 1895 did not build any in 1895, and one other company did not report in the latter year. The *Railroad Gazette* says the larger locomotive works seem to have been in a better position to profit by the large increase of orders, and several of such works built more than twice their output in 1894.

The Bengal-Assam Railway Company has addressed the Liners, inviting them to make Chittagong a port of call to pick up tea to be brought direct from Assam, without passing through Calcutta. The proposal represents a scheme that has no doubt long agitated the promoters of this line, to set up a rival port to Calcutta, to which they should have the exclusive privilege of carrying produce. Apart, however, from the additional run that this would involve, and the somewhat important fact that none of the large liners could ever get up the Chittagong river in safety, the proposal is a visionary one, for water carriage for tea is far cheaper than carriage by rail, and the natural route lies *viâ* Chandpore and Goalundo by the Eastern Bengal State Railway to Calcutta. To facilitate carriage, the Indian General Steam Navigation Company have recently started a much improved line of boats from Chandpore to Goalundo, and there is, says the *Indian Engineer*, no reason to suppose that the present current of trade will be changed.

A correspondent writes on the proposed London and South Wales Railway, to the *Times*:—"The promoters have considered it desirable to withdraw this scheme, and an arrangement has been made by them with the Great Western Railway Company. The promoters have been influenced in this matter by the projection of the new lines of the Great Western Railway Company from Wootton Bassett to Patchway and the advantages which South Wales would obtain by their construction. They have also been influenced by the want of support and the threatened opposition on the part of large interests in Cardiff and various landowners and local bodies along the route. They have protected the public interest as far as they can by arranging that the Great Western Railway Company are to maintain all the facilities recently given to South Wales, to use their best endeavours to get their new lines authorised, and vigorously to proceed with the construction of the same; to make Cardiff an open station; on July 1st next to reduce their passenger fares to South Wales, and to run passenger trains on their Ely and Garw Valley branches; to reduce the coal rates to Southampton, and to use their best endeavours to reduce the cost upon South Wales coal sent to London for bunkering purposes."

NOTES AND MEMORANDA.

The gas obtained from cleveite freed from hydrogen by passing it over red hot cupric oxide, and from nitrogen by means of magnesium, has a density of 2·02 as compared with hydrogen.

The pig iron output for the year 1895 in the United States is estimated by the *American Manufacturer* at 9,387,639 gross tons, which exceeds that of 1890, the year which has hitherto held the record for largest production, the output in that year being 9,202,703 tons. The production during the last two months has been at the rate of about 11,000,000 tons per annum.

In a recent paper read before the Academy of Sciences in Paris, on the presence of sodium in aluminium prepared by electrolysis, by M. Henri Moissan, it is shown that electrolytic aluminium contains in general from 0·1 to 0·3 per cent. of sodium, and that the presence of this impurity renders the metal easily attacked by water. Aluminium should always be used alone and pure, as it readily forms electric couples with every other metal, and is then easily attacked by water.

In a paper on the origin of argon and of helium in gases disengaged by certain sulphurous waters, by MM. L. Troost and L. Ouvrard, it is shown that, though argon is generally present in waters, helium is only found in certain mineral waters, and does not probably owe its origin to the atmosphere, but to the rocks through which the waters have percolated. M. Bouchard added some remarks on the therapeutic value of helium and argon, and supported the view that these gases have no action on the economy, but admitted that the metals present in helium containing minerals might have medical action when present in minimal amounts.

Silica volatilises readily in the electric furnace under the influence of the arc from a current of 1000 ampères and 50 volts, and if the action of the arc is stopped before volatilisation is complete, crystals of silicon, like those described by Senarmont, are sometimes found in the lower part of the crucible. M. Moissan finds that when a mixture of rock crystal and carbon is heated in the electric furnace in a carbon tube closed at one end, the open end of the tube becomes full of flocculent volatilised silica, below which are crystals of carbon silicide, whilst still lower in the tube is a ring of crystals of silicon mixed with some carbon silicide. It follows that silica is reduced to silicon by carbon under the influence of the electric arc.

When electric sparks are passed through a mixture of nitrogen and carbon bisulphide vapour at about 20 deg. sulphur and carbon are precipitated, and the nitrogen is slowly absorbed. A small quantity of mercuric thiocyanate is formed, but the greater part of the nitrogen is converted into more highly condensed products. With the silent discharge in place of sparks, there is no precipitation of carbon, and after some time the nitrogen is completely absorbed. There is no fluorescence, such as is observed in the case of argon and benzine. If the product is heated, some carbon bisulphide is regenerated and nitrogen is liberated; but, according to M. Berthelot, the volume of the latter is much smaller than that of the original gas.

According to the discoveries of Zsigmondi, it is possible, says a contemporary, by the addition of small quantities of protoxide of iron to produce glass which possesses sufficient transmission for rays of light, while allowing the passage of a small quantity of heat only. Such glass is especially adapted to the manufacture of protective shades against radiating heat, which would be of great value to many industries as well as to the single lighting bodies. Of similar importance are these discoveries for the production of good window glass, as well known window glass may show a rather strong green colouring without its being noticed much or disagreeably when put in the windows. By using glass containing protoxide of iron it would, therefore, be possible to detain to the greater extent the radiant heat produced in the interior of the room, as well as the caloric rays of the sun falling from the outside upon the windows. This, however, already happens to a very considerable extent with the every-day glass of commerce.

A remarkable discovery in photography has been made by Professor Roentgen, of Wurtemburg, by means of which, with the light from a Crookes tube, some things which absorb the light may be photographed, while others enclosing these things are unnoticed. Thus he is able to obtain pictures on a photographic dry plate which was enclosed in a wooden case. He also varied the experiments, as by enclosing in wooden cases the objects he wanted to be reproduced, or by wrapping them up in other materials. He also photographed the hand and a larger part of the human body than the hand, and according to the Vienna correspondent of the *Standard*, obtained pictures of the bones only, without their fleshy covering. The light from the Crookes' tube is absorbed by metals and bones, but goes through wood and other organic substances, just as ordinary light goes through glass. Aluminium, however, forms an exception to the rule. The rays which produce the effect are not refracted by glass lenses. Professor Roentgen has sent rays of the new chemical light through aluminium plates of 1½cm. in thickness, and they went as clean through as if the substance had been wood. The same was the case with two sets of books, including many volumes. These he placed between the Crookes tube and an ordinary compass; behind them was the wooden case with the dry plate, and the result was as complete a photograph of the compass as possible. It is, perhaps, not strictly a photograph in the ordinary sense, because no lenses are used.

Making a calculation according to the Ihering-Slaby figures to see how the useful effect of the consumption of coal, liquid acetylene and carbide of calcium compare in operating a 1000-horse power ship engine for a period of 600 hours—twenty-five days—the following figures are obtained:—*a*. Coal. For 600,000-horse power hours are required, at 0·7 kilos. each, 420,000 kilos. = 420 tons of coal, which well packed would occupy a space of 420—430 cubic metres. *b*. Liquid acetylene. According to the concurring statements of Ihering and Slaby 0·18 kilos. per horse-power hour are necessary for large engines, or for 600,000-horse power hours 108,000 kilos. = 108 tons, for which—spec. gravity at 0 deg. = 0·451, at 35·8 deg. = 0·364. In view of the higher temperature of the hold, vessels of at least 270—300 cubic metres volume would have to be provided, which would afford absolute safety at a pressure of fifty atmospheres or more. *c*. Carbide of calcium. To produce 0·18 kilos. of acetylene required for 1-horse power hour from 90 p.c. carbide of calcium, 492 grammes or about 0·5 kilos. of carbide are required, or for 600,000-horse power hours 300,000 kilos. = 300 tons, which with a specific gravity of 2·22 require a space of about 131 cubic metres, which by adding the sheet covering above referred to would not be increased to more than 150 cubic metres. The material necessary then to supply a 1000-horse power engine for twenty-five days would be in case of first coal 420 tons net, requiring a space of 420 cubic metres; in case of compressed (liquid) acetylene 108 tons net, requiring a space of 280 cubic metres, excluding vessels, and in case of carbide of calcium 300 tons net, requiring a space of 135 cubic metres. In making this comparison it must be considered that the operation with steam engines requires a large and expensive boiler arrangement, and that for liquid acetylene two large storage vessels are necessary, while by using carbide of calcium but a few simple and light apparatuses would be needed. Dr. Adolph Frank, of Charlottenburg, writing on this in the *Journ. f. Gasbel and Wasservers*, says: "Such projects, as well as others connected with the production of acetylene, may, as the *American Manufacturer* remarks, appear to some like phantastical music of the future, but they can gain importance very quickly, as soon as the next problem, the cheap production of carbide of calcium on a large scale, is once solved."

MISCELLANEA.

At the Home-office on Tuesday, Mr. Jesse Collings, M.P., presided at the eighth meeting of the committee of inspectors and manufacturers appointed at the conference held in the council chamber, Birmingham, to devise means to remove the anomalies existing under the Weights and Measures Acts.

Mr. A. Cooper, of the North-Eastern Steel Works, and the Acklam Ironworks, Middlesbrough, has been elected President of the Cleveland Ironmasters' Association for the year, vice Mr. F. A. E. Samuelson, of the Newport Ironworks. Mr. George Ainsworth, of the Consett Ironworks, has been elected vice-president.

We have received from Mr. W. S. Hipkins, of Coseley, Bilston, some samples of hammer handles, including a handle of 38½in. length for a flogging hammer, and one of 16½in. for a bench hammer. They are made of excellent straight-grained tough ash not too close-grained. They have defied our attempts to break them; they will take a bend but will not break, and would evidently stand a lot of the jarring of hammer handle work.

Mr. Alfred E. Beach, editor of the *Scientific American*, died in New York on Janvary 1st. He was a man of remarkable energy, and excelled in ideas for improvements in engineering and mechanical arts. Among his inventions were a typewriter and schemes of pneumatic mail transmission, and a pneumatic railway. In the construction of a short section of this road in New York city, use was made of a hydraulic shield for excavating without disturbance of the street surface.

The Cunard steamer Cephalonia, which went on the rocks near South Stack Lighthouse on New Year's morning, and was afterwards grounded in Holyhead Harbour, was successfully floated on Saturday night. The operations have been conducted under the supervision of Captain Watson, marine superintendent of the Cunard Company. Three tugs lay alongside taking off the cargo, while powerful pumps were brought from Cardiff and other ports. The Cephalonia will be temporarily fitted up, and will proceed to Liverpool in about a week.

An American inventor who advocates the use of electricity for propulsion of ocean-going steamers is, it is said, about to equip a steamboat on the following lines:—He will put in his boat a powerful engine of the slow-speed type, connected to a multipolar generator transmitting current to electric motors attached directly to the propeller shafts. The motion of the motors being rotary, a very high speed could be attained with comparatively little vibration, while the reciprocating part of the propelling machine—the engine—could be run at a comparatively slow speed. The further advantage of better regulation in rough weather, when the propellers lift, would be secured.

An important scheme is in progress for further developing the Warwickshire coalfield. A company is being formed with a capital of £150,000 for developing and working the minerals under the estate of Mr. F. A. Newdegate, M.P., at Astley, and other adjoining properties, containing an area of between 2000 and 3000 acres. The valuable coal seams of the district have been proved to exist on the north-east and south sides, and a borehole has lately been put down near the centre of the estate, proving the principal seams of coal to be over 20ft. thick at a depth of nearly 500 yards. The estate is in close proximity to the London and North-Western and Midland Railways, and is likely to prove of much importance as being the nearest coalfield to the London market.

A new lamp, the invention of Mr. Ludwig Durr, of Bremen, is being tried by our military authorities. "The light is originated by evaporation and superheating of the vapours from ordinary petroleum. Air is drawn into the lamp between the gasifier and an external cylinder, and a smokeless flame of great brilliance is produced. In short, vapours are produced by intense heat and converted into gas, which, upon being burned, yields a light ranging from 3500 to 14,000-candle power. The apparatus is self-acting and does not necessitate the employment of compressed air. It is so constructed that a lamp and reservoir capable of holding 10 litres of petroleum, and supplying a 3500-candle power light, can be strapped on to the knapsack of a soldier. The lamps can be carried about when burning or may be fixed in any position."

The application of machinery to glass bottle manufacture has formed the subject of a correspondence between the Duke of Devonshire and Mr. A. Greenwood on behalf of the glass bottle manufacturers. Speaking on technical education in Birmingham last month, his Grace, quoting from the prospectus of a company to be formed for making glass bottles by machinery, spoke of the machine as "producing bottles at 3d. a gross against 3s. 6d. by the hand-blowing process, and its producing eighty gross a day by boys without men, and a saving of 33 per cent. waste," &c. Mr. Greenwood has written to the Duke to state that "up to the present time the invention referred to has never been taken up by a single glass bottle manufacturing company in the United Kingdom, except the original one, which collapsed, and that not a single machine is now in operation in the kingdom." The Duke of Devonshire, in acknowledging the communication, states that his remarks had references to the advantages claimed at the time for an invention, among others, which illustrated the application of science to industry, but his Grace's information did not then show that the particular process had proved unsuccessful.

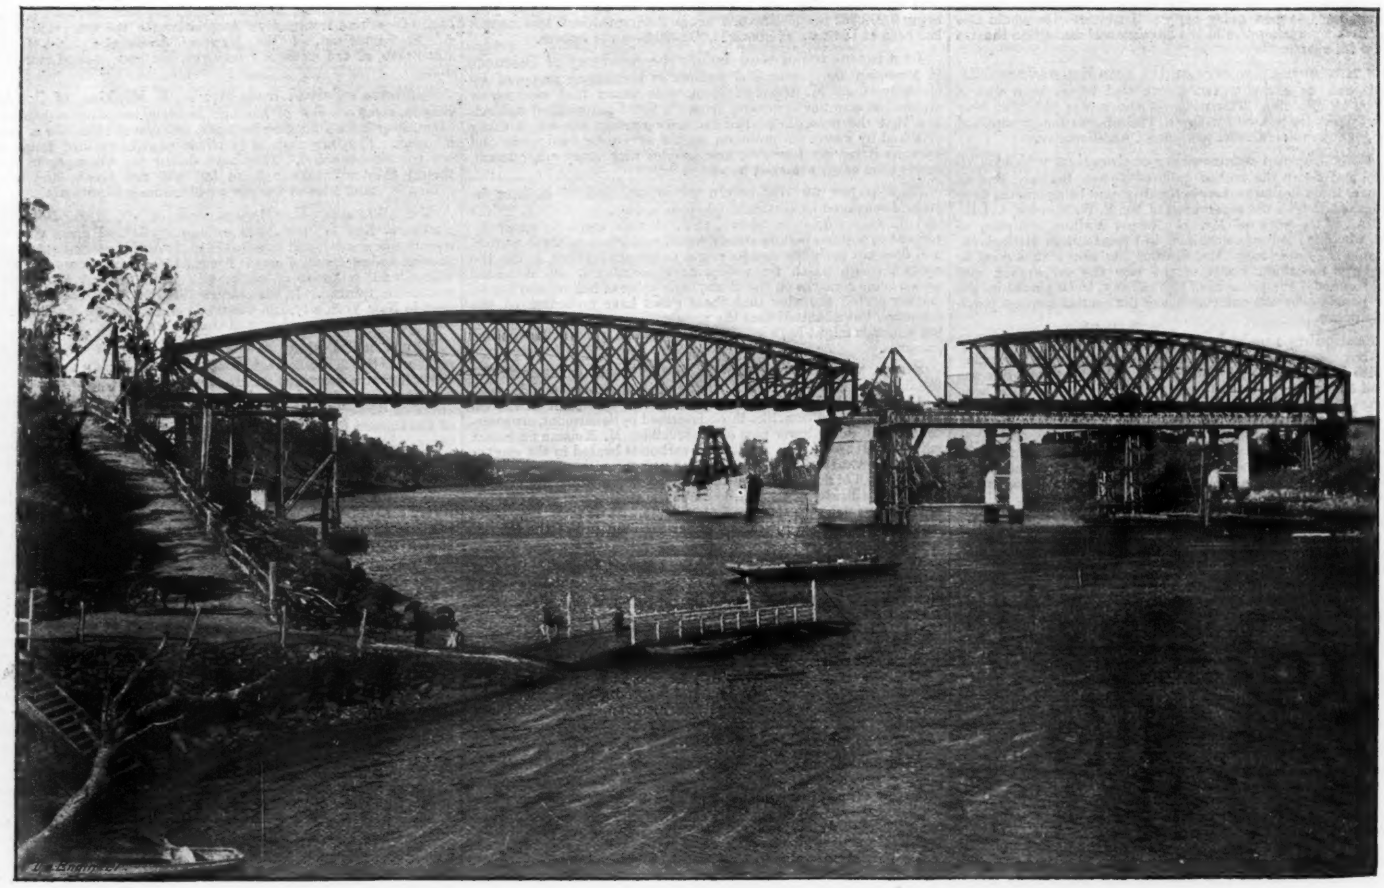
The report of the Yorkshire coal trade with Hull, issued by the Hull Chamber of Commerce and Shipping, shows a very large increase in the business done during the month, and a decrease on the twelve months. There were sent to Hull last year 2,190,016 tons, as compared with 2,256,824 tons in 1894, or a decrease of 66,808 tons. The amount forwarded in December reached 184,496 tons, as against 159,128 tons in the same month of 1894, an increase of 25,368 tons. Denaby Main again heads the list with 25,368 tons, as compared with 31,480 tons in December of 1894. The same colliery occupies the lead for the year with 328,888 tons, as against 256,968 tons, or an increase of 71,920 tons. Manvers Main comes second, Carlton Main third, and Aldwarke Main fourth. Sixteen South Yorkshire pits sent to Hull last month 110,760 tons, as compared with 41,248 tons from the same number of West Yorkshire collieries. In the exports to foreign countries, Sweden and Norway are again at the top of the list with 22,944 tons in December; 297,661 tons in the twelve months. North Russia comes second with 192,648 tons on the year, and 3117 tons on the month. Germany took 12,899 tons last month, and 134,728 tons during the year.

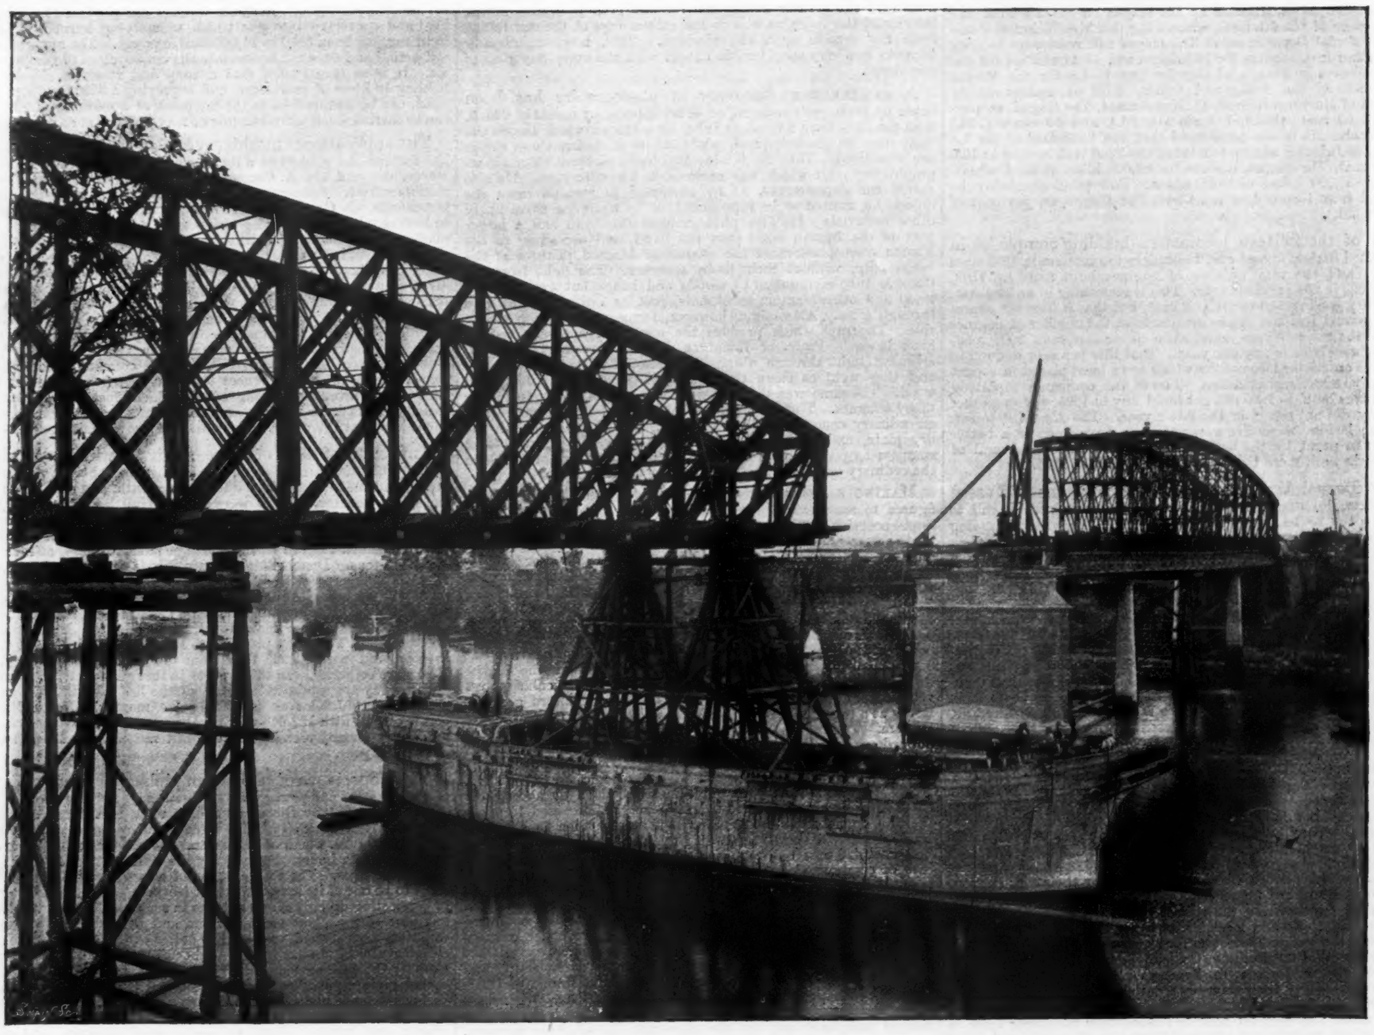
The importance of safe steam piping in central stations of electric light and power plants is again, says a recent *Engineering News*, illustrated by the accident last week in a Brush arc light station in New York city. The bursting of an 8in. cast iron elbow ruined 3000 dols. worth of belting and put the station out of service for twenty-four hours. Fortunately the station attendants escaped with their lives. The steam piping of a large central station has come to be one of its most important features, owing to the practice of connecting up boilers and engines in such a manner as to permit any part of the plant to be cut out, and the attempt to provide duplicate pipe systems to a greater or less extent. It is worth considering whether better results might not be secured by striving to simplify the pipe systems so far as possible, and instead of duplicating piping, putting sufficient additional expense into the single line of piping to make it absolutely safe. In many cases it is likely that the expenditure of more intelligence in the design of the piping and greater efforts to secure good drainage, and avoid strains due to expansion and contraction, would result in great improvement. It should be understood by the builders of such stations that the design of the steam piping is too important a matter to be left in the sole charge of an ordinary steam-fitter.

THE ALBERT BRIDGE, INDOOROOPILLY, QUEENSLAND

MR. H. C. STANLEY, M. INST. C.E., ENGINEER; MESSRS. J. McCORMICK AND SON, CONTRACTORS

(*For description see page* 52)





FOREIGN AGENTS FOR SALE OF THE ENGINEER.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, January 21st, at 8 p.m. Paper to be discussed: "The Sanitary Works of Buenos Ayres: Sewerage, Drainage, and Water Supply," by the Hon. R. C. Parsons, M.A., M. Inst. C.E.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, January 21st, at 3 p.m. Lecture: "The External Covering of Plants and Animals: Its Structure and Functions," by Professor Charles Stewart, M.R.C.S., F.L.S. Thursday, January 23rd, at 3 p.m. Lecture: "Dante," by Philip H. Wicksteed, Esq., M.A. Friday, January 24th, at 9 p.m. Discourse: "Ludwig and Vitalism," by Professor Burdon Sanderson, M.D., D.C.L., LL.D., F.R.S. Saturday, January 25th, at 3 p.m. Lecture: "The Valley of Kashmir," by Walter R. Lawrence, Esq., I.C.S., C.I.E.

SOCIETY OF ARTS.—Monday, January 20th, at 8 p.m. Cantor Lecture: "Alternate Current Transformers," by Dr. J. A. Fleming, F.R.S. Wednesday, January 22nd, at 8 p.m. Paper: "Supply of Sea Water to London," by Frank W. Grierson.

DEATHS.

On the 9th inst., suddenly, at Upper Norwood, HUMPHREY CHAMBERLAIN, M.I.C.E., late of Montevideo, eldest son of the late Humphrey Chamberlain, Barnsley, Yorkshire. Friends kindly accept this, the only, intimation.

THE ENGINEER.

JANUARY 17, 1896.

THE MINERS' CONFERENCE.

AMID the troubles which perplex English people abroad, we must not lose sight of a gathering which may mean an industrial conflict at home. At the annual conference of the Miners' Federation of Great Britain, held at Birmingham this week, there were delegates from Yorkshire, Lancashire, Midland Federation, Derbyshire, Notts, Leicester, South Derbyshire, North Wales, Cleveland, South-Western Section, and the Scottish Federation—in all forty-one delegates, representing 159,331 persons in different unions, out of a total of 298,269 miners employed in the districts covered. It will be noted that several important localities are here unrepresented, viz.:—Northumberland, Durham, and South Wales. Interest mainly turned upon the address of the President, Mr. Picard, who, when he rises, rises like the Nile and spreads himself over pages of space. His presidential address on this occasion, as reported in the Yorkshire papers, extends to over four columns. At the point where the public look for information and guidance they will find it hard to discover any. The Rosebery arrangement terminates in June, and the question which everybody is asking is this—Is that arrangement to be continued, or are we to have another coal war on its expiration? Some months ago Mr. Pickard was asked for an answer to this inquiry, and his reply was:—"Wait till the Miners' Conference in January." The Miners' Conference has been held, and the public is no wiser. We gather, however, from the drift of Mr. Pickard's speech, that in spite of the downward trend of coal values, the increasing difficulty of working any but the large mines, and the gradual absorption of the coal workings by huge concerns, there are to be no concessions whatever from colliers. There is something plausible in what Mr. Pickard puts down as the miners' watchword for the future, "Men must live by their labour, and a living wage must be paid where coal is got." There is no desire to dispute the right of the miners to a living wage; the only point is whether Mr. Pickard and his Federation are going the right way to get it. He and his colleagues have laboured during the reign of the Rosebery Agreement to reverse the economic law that values govern wages. They have sought to establish during that time the theory that coal values need not fall if coalowners make up their minds that they shall not fall, and that whether they fall or not a certain wage must be paid to the coal getter. This theory, of course, is against all well-established economic principles; and although the wages have been paid, the values of coal have not been maintained. The result, as we have said, has simply been that the smaller collieries have gone to the wall, while business has accumulated in the hands of the larger coalowners, with every prospect that this tendency will be acutely accentuated in the future. Mr. Pickard himself expects that the collieries in course of being opened out will produce, when in full play, an additional output of about one-third. He must know that that production will be in the hands of the great colliery undertakings, and that as no concession is to be had in regard to wages, increasing efforts will be made to obtain an enormous output at proportionately less price per ton in the getting. We say nothing at present as to the points emphasised by Mr. Emerson Bainbridge in regard to existing Continental competition, which is already cutting off some of our northern markets, and the almost certain development of the coal fields in the Far East. The first is already an ascertained fact, and it is coupled with eqully certain data, which prove that the Continental miner—in Germany, Austria, Belgium, and France—works for nearly one-half, and in some instances quite one-half, less wages than the British miner. These are facts which cannot be talked away, and it is no answer to say that "the British coal producers can more than compete with any nation in the world, even in their own markets." It is simply shutting our eyes to an immediate danger to say, as Mr. Pickard says:—"All the information we possess in regard to the exportation of coal from this country leads us to infer that British coal fears no competition with foreign markets, and it is quite clear that those who sell the coal to the foreigner know well that it pays, otherwise they would not go on exporting it to the extent they do." Every person conversant with coal mining knows that contracts must be taken to keep the pits going a certain number of days per week. It is not always possible to get a paying price, but many a coalowner takes less than he would like to have, so that when the opportunity offers for more favourable prices, he may be able to take advantage of it to spread the cost of production over a greater output. That is not, we admit, the most desirable condition of affairs, but it is inevitable, and as a fact must be fairly faced. Mr. Pickard alludes to collieries which, he says, have made handsome fortunes for their owners. No one denies that money has been made out of coal, but why not put the debit as well as the credit side of the account? For every colliery which, during the last half dozen years, has made a huge profit, there could be named half-a-dozen which have made none at all, and many worked at a loss are now completely laid aside. No one denies the right of the collier to a living wage. Everyone wishes he may get it and a good one. But is there no such thing as the right of a living dividend? A large portion of the colliery undertakings of the country are now in the hands of limited companies. Limited companies are composed of shareholders, many of whom are dependent upon their dividends for their existence, quite as much as the collier is upon his wage at the week's end. Have those who advance the money which keeps collieries going and find colliers work, no claim whatever to a reasonable return upon their capital? Mr. Pickard makes no mention of them. He talks wildly of a "millennium of greed," about workmen being "fair game for the heartless speculators," whom he describes afterwards as "greedy horse leeches." The hardship, however, is not with the speculator but with the *bonâ fide* owner, who has put his money down a pit and expects a return for his capital on quite as honest grounds as the collier expects his wages for his work. The public, too, have surely some right to be considered. If protection spelt with a big "P" is to be resolutely maintained in the coalfield with a view to making the public pay more for the coal than it is worth in a fair market, why are these very Miners' Societies opposed to protection in other industries? The argument is that they must draw a ring fence around coal, otherwise the getting of it will not pay the getter. But has not this been the case for a long time in agriculture? Farmers have found it impossible to farm at a profit; farm labourers have been dismissed in thousands, and land, miles upon miles of it, in every agricultural county, has gone derelict. Yet Mr. Pickard and his people do not propose a living wage for the agricultural labourer, or seek to secure it by giving him the protection which they demand for the collier. Were he but to think a bit he could have a convincing argument in favour of ranking farm labourers in the favourable industrial treatment which he claims for the collier, for when the farm servant leaves the land where does he go? He goes straight down the pit, where he competes with the collier, and tends to make that over-abundance of labour which is the chief cause of there being more workers than work in the coalfields of England. The farm servant's presence there is not only diametrically opposed to the wage interests of the miner, but is in a measure a menace to his safety at work, for he is not, and he cannot be expected to be, so thoroughly acquainted with the conditions of coal seams, fiery and otherwise, as the man who has spent his life from a boy upwards in the bowels of the earth.

It has been suggested to Mr. Pickard that one of the first steps to "steady" wages at home would be to utilise some of these International Miners' Congresses to "level up" the Continental miner to something like the British standard. That would cut off one form of keen competition. But he cannot see his way to a crusade of this sort, and, meanwhile, there are grave inequalities at home by which one coalfield, by cheaper labour, is able to undersell another. That is not the fault of the employers, and it proves that, after all, the Miners' Federation, though powerful enough as was painfully proved by the last coal war, cannot even command uniformity in wages throughout the coalfield at home. So long as one district is able to bring its product to bank under wage conditions 10 to 15 per cent. lower than another, there must be a loss of trade to the handicapped localities, which, by the way, are those in which Mr. Pickard himself, from the labour standpoint, is the most potent factor.

ADMIRALTY CONTRACTS.

OUT of evil good may be wrought by those who know how to profit by opportunity; and the difficulties and alarms which disturb the nation may suffice to silence for a time, if not for all time, those who preach economy in naval expenditure, who tell us that ships of war represent waste, and that all the rest of the world is full of peace and charity and the other gentle virtues. We do not doubt that large additions will be made to our naval strength. Indeed, it is not only possible, but right and proper, that our shipbuilding programme for the next half-dozen years should represent a very large expenditure, and the occasion seems to us fit and suitable for the discussion of the system on which we obtain our warships, and the relations prevailing between the Admiralty and the great shipbuilding and engineering firms of this country. It may be said, perhaps, that the moment is not opportune for criticising Admiralty policy; we hold, however, a contrary view. Nothing that we are about to say can in any way hamper those in authority at Whitehall, and it is of extreme importance that at the conclusion of one programme and the beginning of another, the system, or want of system, adopted in spending very large sums of money should be criticised, that the facts should be made known, and desirable changes effected.

For a long time past the relations of the Admiralty and contractors have been strained. Complaints reach us from many different directions. In some cases they refer to very large matters indeed, in others to comparative trifles; but great or small, they all tend to prove that between the Admiralty and contractors there is friction, and this friction is not for the good of the country, and might be easily avoided by the exercise of tact, and a recognition of the truth that "red tape" may be a very objectionable thing. Let us consider what the system is. If a new vessel is required, certain firms on the Admiralty list are asked to tender, and tenders are sent in. This is all straightforward, and as it should be; but, instead of the Admiralty accepting or declining particular tenders with an evident intelligent perception of what the tenders mean, a system of bargaining commences. "A's" tender is used as a lever to reduce "B's" tender, and the result again is used to cut down "C's" prices. All this is very undignified in a great public department. It may be urged, however, that as the Admiralty have to spend national funds, of which they are in a sense trustees, no other course is open than to try to buy as cheaply as possible. To this we reply that the duty of the Admiralty is to obtain the best possible ships, engines, guns, &c., that can be had; and that those who have to consider the tenders ought to know when a tender is too high or too low. In a word, they ought to know the value of what they propose to buy. Whether the knowledge does or does not exist in the Controller's department, we are unable to say; apparently it does not. The actual method of obtaining ships is strictly analogous to that adopted by a man who, totally ignorant of what a dwelling-house ought to cost, first gets drawings from an architect, and then advertises for tenders. Having obtained them, he proceeds to pit the tenderers against each other, assuming that in this way he will get the best value for his money. The mere mention of this method of doing business will be enough to condemn it in the eyes of our readers. But there is ample evidence available that the Whitehall people do not know what is the proper price to pay for work or materials, and to this ignorance on the one hand, and on the other to a fear of being cheated based on that ignorance, is no doubt due the bargaining and bartering which during the last few years have gone on at Whitehall, and have at last become so vexatious that it is matter of common talk among those firms who have laid themselves out to execute Admiralty orders. The following little incident may be cited as an example of what we mean. The sums concerned are insignificant; the lesson taught is no less suggestive and important. Messrs. Yarrow and Company provided certain additional parts in one of their vessels, and made a charge for them as an extra of £20. Whether this was a fair amount or not we have no means of judging. The Admiralty offered the firm £7 10s. This was refused. Then the Admiralty offered £10. This was declined, and the firm wrote to say that having made a proper charge in the first instance, they could not accept less, but that, as the Admiralty thought differently, they would make a present to the country of the additions; thereupon the Admiralty sent the full amount claimed. Now, if the work was really only worth £7 10s. the authorities certainly did not do their duty when they offered £10, and still less did they do it when they paid £20. If, on the other hand, £20 was the proper price, why in the name of honesty did they offer the contractors £7 10s.? In another case, with a different firm, certain work was, we are informed, passed by an inspector. Subsequently this work was condemned by another inspector—not, be it observed, because the contractors were held to be in fault—and constructive changes were introduced representing an outlay of some thousands of pounds. When the bill was sent in the Admiralty offered half the sum demanded, and then went on offering more and more, and finally, we believe, the whole question was referred to arbitration. We could cite many instances of the same kind. A policy and a system lending itself to such transactions cannot but be bad for the country. The general result is that contractors accept what the Admiralty offer, and are now protecting themselves by asking a great deal more than they expect to get. In some cases this is done directly; in others it is done indirectly by allowing in the terms of the tender a larger margin for contingencies than would otherwise be needed.

It must not be forgotten that there is a clause in the Admiralty contracts to the effect that in case of dispute the sole arbiter is the Controller of the Navy. A little reflection will show that although in the old days of sailing ships such a function might be properly discharged by a seaman, an admiral is not the right man in the present day. To the ordinary business mind it appears that the proper person to arrive at a decision on vexed points would be one having some personal knowledge of work — the time it represents, the value of labour, &c. &c. Now, the Controller of the Navy is an admiral, and never, of course, received any training in his life of the kind needed. He cannot possibly of his own knowledge say whether a charge is or is not too high, and he must place himself in the hands of subordinates. It follows, therefore, that the Controller is only the mouthpiece of departmental officials, and that in so far as this question of the cost of work is concerned, the theory that a very high and impartial official will weigh the interests of the contractor on one hand, and those of the nation on the other, has no foundation in fact. But it may be conceded at once that the Controller of the Navy ought to be an admiral. It follows, therefore, that on some one else should devolve the duties of arbiter—on whom we shall not attempt to determine, but obviously one who by his training and experience possesses the necessary qualifications. It is, we may add here, a noteworthy fact that neither the Assistant Controller and Director, nor the Engineer-in-Chief of the Navy, has anything to do with this question of prices, all the financial work connected with contracts devolving on another department. The functions of the Controller as an arbiter are quite subordinate to those of another kind for which a seaman's knowledge is indispensable, and we have no doubt that he would gladly be relieved of a troublesome duty. But waiving for the moment this aspect of the question, we come to another of perhaps greater importance,

It ought to be clear that the relations prevailing between the Admiralty and the shipbuilding and engineering firms of this country ought to be of the most cordial description. If we trace the history of the progress of the Navy, it will be seen that it has been the result of the labours of the great engineers and shipbuilders of the nation, and not of the Lords of the Admiralty. On the contrary, it is not too much to say that up to a very recent period successive Boards of Admiralty did all that in them lay to retard progress, and we cannot call to mind a single instance in which they originated anything. A Board of Admiralty opposed tooth and nail the use of steam, another Board opposed the screw propeller. It was only with the greatest difficulty that the compound engine was forced on a reluctant body of sailors by the efforts of chief constructors and engineers-in-chief. Armour was opposed. In short it is matter of common knowledge that the Navy as we have it has been built up to its present perfection in spite of Whitehall. But the proper policy for the nation to pursue is to encourage those who, not content with what they have done, continue to do better and better. Instead of this, the Admiralty policy has been mean to the last degree. It is a fact which admits of easy proof that it is dangerous to the interests of a contractor to devise an improvement. Here is an instance: the Russian torpedo destroyer Sokol was the first vessel of its type built in Great Britain of nickel steel; she was to a large extent experimental, and her builders accepted the risk. The Sokol has been a great success. The Admiralty will ask for nickel steel in future, but they will be very unwilling to pay an extra price for it. If Messrs. Thornycroft build for a foreign Government a boat faster than ever was built before, the Admiralty will insist on having equally fast boats, but they will higgle over the price, and obtain tenders from other firms who can profit by the experience of those who have done all the experimental work. Nor is it to be supposed that one firm is better treated than another. The Admiralty are always prepared to utilise the information supplied by one firm to cut down the tenders of another. Statements such as these ought to be substantiated, and there is no difficulty in doing this. Sometime since we had occasion to allude in very strong terms to the action of the Admiralty in distributing Messrs. Yarrow's detailed working drawings of the machinery of the Havock among a large number of firms who were, for the first time, attempting the construction of this kind of vessel, and this was done without first consulting or gaining the sanction of the firm whose designs were thus dealt with—designs, as is well known. arrived at by long experiment in this special class of machinery. A more unfair proceeding it is impossible to imagine. The injustice of making use of the Yarrow designs in the manner described was strongly condemned by some influential Members of Parliament at the time, and it led to a statement in the House by the Secretary of the Navy, which although probably considered by the outside world as a compliment to the Poplar firm, was practically a public apology on the part of the Whitehall authorities for the wrong they had done. But this is not all. On examining the last published Navy Estimates, we find that the average price paid for the destroyers built in the North was several thousand pounds more than that paid to the London builders for the first vessels of this type, in spite of the fact that many of the firms in the North had Messrs. Yarrow's designs furnished them as a guide. In the Navy Estimates the Havock and Hornet are put down as costing £33,174 each, while the vessels ordered from three of the firms on the East Coast, at Newcastle and Sunderland, averaged between £37,000 and £38,000 each.

It must not be assumed that we wish to convey the impression that Messrs. Yarrow have been treated with exceptional injustice. The Admiralty seems to be ubiquitous in doing just that which ought not to be done, and doing it with a very high hand. It may be admitted that the Controller's department has difficult cards to play, but the difficulty is not by any means insurmountable, and is augmented by the department. But there is a higher interest at stake than that of the engineers or shipbuilders of Great Britain. It is the welfare of Great Britain herself. Foreign Governments compete with our own for the work of such firms as Thornycroft and Yarrow, Armstrong and Humphreys, and they get it. Ask where we will, in what port we may, alike on the Thames and the Clyde, the Tyne or the Mersey, we get the one answer: "It is better to deal with a foreign Government than with the Admiralty." This should not be. Instead of building for foreigners, our private yards should be full of work for England. Orders for 30-knot destroyers have recently been placed. It is worth comment that none will be built at Poplar—why, we may perhaps explain at another time; but Messrs. Yarrow, although they have not taken orders from our own Admiralty, are building for foreign Governments. Comment on such a fact, at such a time, is needless. We have said enough, we think, to show that some change for the better in the Admiralty contract system is imperative; and we trust that the attention of Parliament will be directed to the subject soon after it meets.

A writer obviously well informed, in the pages of one of our daily contemporaries, commenting on Admiralty policy, says:—"It is nothing but a breach of trust, and is resulting in what any one with any forethought would have expected, namely, in the disgust of firms of contractors who have in past times been the best friends of the naval authorities, and of the Navy, and in their no longer caring for British Government work, and laying themselves out to supply foreigners, and to send their best productions abroad." We cannot think that the public will regard with favour a policy that permits England to be outbidden for the fastest craft in the world, or makes it better worth the while of Armstrong or Laird to build for a foreign Government than for England. We do not advocate waste; we have no desire to see private firms paid exorbitant prices, nor, it is fair to say, do they want them. What we urge is that the Admiralty is not quite in the position of a limited company. There are national interests to be considered. The building of warships for ourselves should be encouraged. The building of warships for other nations should be discouraged. The relations of employer and employed would be improved, both at Whitehall and outside it, and the chance of the occurrence of labour troubles would be diminished by the display of a little more liberality on the part of the Admiralty. There is such a thing as being penny wise and pound foolish. We have no desire to attack anyone. We express the opinion of all the important shipbuilding and engineering firms in the kingdom, when we say that the existing Admiralty contract system is faulty, and that reform is urgently needed. In what that reform shall consist it is for Government, which is superior to the Admiralty, to decide. To us it appears that nothing more is needed than the adoption of broader and sounder views as to the relations which should exist between the State and engineers and shipbuilders.

A QUESTION OF TRAIN RESISTANCE.

IN this country, when an individual or a newspaper makes a statement which is contrary to or beyond experience, it is customary to regard the statement with doubt, and to ask for a proof of the matter. Nor is offence taken. The maker of the statement understands that being outside experience, and in a manner quite new, it will have to be substantiated by evidence which must be the more exact, complete, and trustworthy, as the statement to be confirmed is more difficult of general or special acceptance. In nothing is this proposition more true than in technical or scientific affairs. In the United States, however, they manage matters differently, and we are bound to accept every statement made, or run the risk of being considered impertinent and offensive. The latest example is supplied by an editorial article in the *Railroad Gazette* of December 6th, 1895. The point at issue is one of sufficient importance to justify reference to it here at some length.

It will be recollected, perhaps, that in our issue of November 15th we criticised what purported to be an official statement, to the effect that a locomotive very similar to an English six-coupled goods engine took a train weighing about 224 tons, including engine and tender, at the average speed of 72·91 miles an hour on the Lake Shore and Michigan Southern Railway, and this not for a mile but for a run of eighty-six miles. The engine has 5ft. 8in. driving wheels and a bogie, and cylinders 17in. by 24in. We had not the least hesitation in saying that such a performance was outside all our English experience. We may say further now that it is outside all American experience as well, and we have asked, and now ask again, for further and detailed information, which we may add has never been published. Analysing the performance, we showed that the boiler could not be expected to produce more than about 700-horse power of steam, and that in that case we must believe that a bulky train, weighing 224 tons, could be propelled at 73 miles an hour by a tractive effort representing about 15 lb. per ton. Our contemporary quarrels with us, and, accepting these figures as perfectly true, goes on to mix up two things which are quite distinct, namely, the internal friction of a locomotive regarded as a steam engine, and the specific resistance opposed by the track to the locomotive regarded as a vehicle. Now it so happens that some few years ago another journal, the *American Engineering News*, took up this question, and, having quoted certain experiments which proved that the pull on the draw-bar between the engine and the train represented less than half the indicated power, proceeded to advance certain views, and generally accepted as sound the explanation of the fact which we gave. To this we shall refer in a moment, but we must first point out that the *Railroad Gazette*, after combating our statement about the boiler power of the engine, subsequently adopts as correct our estimate of 700-horse power, and then says plainly that the resistance of the train at seventy-three miles an hour was but 15 lb. per ton. Now, as regards the internal friction of the engine, we need not concern ourselves. No doubt the internal resistance of a six-coupled engine is greater than that of one with single drivers. What we have to do with is the resistance of such an engine as a vehicle, and in saying that it is much greater than that of any other vehicle in the train, ton for ton, we only assert what is well known to every railway man. Our contemporary, feeling that we have some grounds for our argument, says:—"Of all the fallacies that have ever been published about locomotive performance 'in the States,' one of the most unwarranted is the statement which THE ENGINEER has remembered, that 'not more than about one-half the horse-power of a locomotive is available for hauling the train.' The statement was made by an irresponsible publication, and we are surprised that any one should have taken it seriously. It carries the presumption that the engine in itself, without regard to its weight, absorbs one-half of the power which it generates. This is a simple case of distorted facts."

Now, so far as we can see, the *Engineering News*, far from being an irresponsible journal, is as well conducted and as influential as the *Railroad Gazette*. They are both responsible and respected on this side of the Atlantic. We learn, then, from the pages of the latter that everything that appears about railway matters in the American technical press is not necessarily true. A similar statement is the head and front of our offending. As our contemporary puts it, the proposition we have quoted is simply a case of distorted facts, and he has himself distorted them. There can be no doubt whatever that the draw-bar pull of a locomotive is not nearly the equivalent of the horse-power exerted; and we have explained this fact on the ground that the leading wheels of the locomotive are always running up hill, because of the deflection of the rail under their tread. Everything has to be brought down to its bearings by the engine. It is the yielding of the road that is accountable for a very large percentage indeed of train resistance, and it is by no means impossible that the resistance at very high speed is comparatively small, because the inertia of the road prevents it from sinking as much as it would sink under the longer continued pressure proper to smaller velocities. This is a point, however, on which we do not dogmatise; we are content to suggest. Struggle with the facts as he may, however, it is indisputable that the resistance of the vehicles of the train behind the locomotive must have been much less than 15 lb. per ton, if the power exerted by the locomotive was but 700-horse power and the speed 73 miles an hour. This proposition makes an extraordinary demand on our faith. Our contemporary, instead of supplying us with aids to belief, draws yet further on our powers. For he says: "It has been shown in these columns that the entire train resistance taken from the power of the cylinders, and *pro rata* over the whole train, without making allowance for the internal friction of the engine, has been in some cases only about 12 lb. per ton at about 90 miles per hour." Nothing of the kind has been proved either by the *Railroad Gazette* or any other journal, or individual, for the simple reason that no locomotive hauling a train has ever attained a speed of 90 miles an hour on a level. If that velocity has been got at all, it has been got down hill, and for so short a time that the relation between the indicated power and the resistance could only be estimated. Our contemporary ought to understand that this question of train resistance has an importance quite outside the pale of newspaper controversy. The proper way to treat the matter is that which we have already indicated in the concluding sentences of the article which has stirred up the wrath of our contemporary against us. We wrote: "It is not for us to say that official figures lie; but it is open to us to say that if the speed said to have been attained on the line on the day named was really attained, then it is certain that there is some peculiarity about American track and American rolling stock that is not found elsewhere in the world; and we advise all railway men in the country to hasten to ascertain what it is. Ostensibly the performance was almost impossible on a level, or compensating track." We have nothing to withdraw. We do not say for a moment that 86 miles were not run at nearly 73 miles an hour. But it remains for our contemporary now to show how a result which has never been got in this country has been got.

We have in England roads which it is impossible to excel. The Great Northern, the London and North-Western, and the Midland track is at least as good as anything on the Lake Shore and Michigan route. The mere rolling resistance cannot be greater on one of these roads than it is on another, save to a degree represented by a most insignificant percentage. There is not one scrap of evidence available, however, to prove that on our roads the recorded resistance in any experiment with a train was as low as 15 lb. per ton at 73 miles an hour. We have no records indeed of any experiments at this speed, for the simple reason that it has never been attained save for very brief periods, even by trains which were not fitted with recording apparatus. The *Railroad Gazette* speaks airily of train resistance, as though its amount at high velocities was a matter of common knowledge. We are quite willing to confess that we know next to nothing about it. We challenge our contemporary to advance evidence at once trustworthy and detailed to prove that he is in a better plight. Finally, we come down to minutiæ. Our contemporary has in a manner pinned his reputation on the accuracy of the report which we have criticised. We have asked for further information. We have, perhaps, been misunderstood. We explain. We want to know the gradients of the specific section of the Lake Shore and Michigan Southern line, between Erie and Buffalo Creek. We want to know how the maximum speed attained, stated to be 92·3 miles an hour, was recorded? We want to know what the axle-boxes were like, and the method of lubrication. We want to know what the weather was; in one word, we want to know what were all the conditions under which the most extraordinary bit of travelling in the history of the world was done; and we want all this information, not for the purpose of winning a dialectical argument over our contemporary, but in order to place the facts before the railway world at this side of the Atlantic, so that here in Great Britain we too may be able to run a train weighing 244 tons, with a six-coupled goods engine, at 73 miles an hour from this to York, or Leicester, or Bristol, or Birmingham. If that can be done with a goods engine, what may not be possible say, with one of Mr. Aspinall's flyers on the Lancashire and Yorkshire Railway, or one of Mr. Stirling's big singles on the Great Northern?

◆

ENGLISH ENGINEERS AND FOREIGN MARKETS.

AN analysis of the annual statistics relating to our machinery exports, of which last week only the bare totals were given, shows that, compared with 1894, the value of the 1895 machinery shipments, excluding steam engines, was an improvement of 11 per cent. This satisfactory state of affairs is due mainly to greatly increased orders for mining machinery, and also for textile machinery, English engineers having, compared with 1894, received more money from abroad for the former class of goods by 86 per cent., and for the latter by about 20 per cent. It is to the enormous activity in South African mining that the credit of the larger increase is chiefly due. This market during 1895 has absorbed about two-thirds of the aggregate trade done with all countries in mining machinery, and so gigantic have been the strides which it has made during the twelve months just passed that the value of the machinery sent there has a good deal more than doubled compared with 1894, having increased from £237,484 to £487,610. Such a showing will increase among English engineers and machinists their regret that the Transvaal difficulty should have arisen, and their satisfaction that a settlement is being arrived at. Another very pleasing feature of the annual mining machinery statistics is the advance made by Australia, which has been so rapid as to suggest the leaps and bounds of her emblematical kangaroo. The figures last week available show indeed that the trade of 1894 has actually been multiplied more than seven times over, for it has risen from £12,270 to £86,265. We are accustomed to fluctuations in the mining machinery returns, but those to which attention has been called probably "beat record," and should have the effect of making British mining engineers particularly keen upon African and Australian trade in 1896. Textile machinists have done a trade during the year amounting to the handsome total of more than six millions sterling, and absorbing about half of the aggregate trade in machinery of all kinds (exclusive of engines). European business has brought in about two-thirds of their income, having been augmented during the year by some 9 per cent., and standing now at not far short of four millions. Second place is taken by India with £827,150, or an 8 per cent. improvement. Business with the United States has more than doubled, having risen from £233,470 to £478,989. With nearly all markets we have done better than a year ago in miscellaneous machinery. The net drop of 9 per cent. in steam engines of all kinds has been due to agricultural and miscellaneous sorts, and has not affected locomotives, which have progressed in value from £749,586 to £799,597, the chief contributory advances being India 50 per cent. (from £204,091 to £305,327), and South America over 7 per cent.

LITERATURE.

Coal Pits and Pit Men. By R. NELSON BOYD, Mem. I.C.E., Second Edition. Revised and enlarged. Crown 8vo., pp. 356, with 36 illustrations. London: Whitaker and Co. 1895.

WE are glad to see that this book has been so well received, that a new edition has been asked for in what, considering the special nature of the subject, must be called the short time of three years. In the new volume, without departing from his original plan of describing the changes that have been made in the legislation affecting the working of coal mines in continuous chronological order, the author has taken the opportunity of adding a preliminary chapter, taking a general survey of the whole subject; and a full digest of the Report of the Royal Commission on Accidents in Coal Mines, which was only briefly noticed in the first edition, has been added. The history of the coal trade has also been continued to the end of 1894, bringing in an account of the great strike in the Midland districts in 1893, and there is a notice of the Report of the Royal Commission on the Aged Poor. The technical part has also been enlarged both in the text and illustrations, the latter including several good figures of hauling and other engines, and reproductions of some of Mr. Arthur Sopwirth's excellent photographs taken underground by magnesium light. These additions, while increasing the size of the volume by nearly one-half, have considerably improved it, making it a useful, if somewhat one-sided, contribution to economic history which, from its popular style, is likely to be of interest to many readers in addition to those technically familiar with the subject. We fear, however, that the author's sympathies with the working classes lead him at times to overstate his case, as, for instance, when he assumes, in the absence of statistics, "that the number of men injured in and about coal mines cannot be much less than 100,000 per annum, and a large proportion of these would be sufficiently injured to weaken even a robust constitution." This appears to give one non-fatal accident for every 1800 or 1900 tons of coal raised; while in the Kingdom of Saxony, where statistical returns under the Compulsory Accidental Insurance scheme are available, the proportion of injuries involving total, partial, and temporary disablement in 1894 corresponded to one in 22,300 tons. Now, as we can scarcely imagine that coal mining is twelve times as dangerous, or that miners are twelve times as careless in England as they are in Saxony, we cannot accept the author's 100,000, except as a symbol for a large number. We are also in doubt as to his scheme for establishing pensions for miners, based upon voluntary savings effected on the security of the State, with a provision that the money paid in should be returned on demand, and the pension, with an equitable addition by the State, claimable at a reasonable age, say, fifty years. This, no doubt, would, in the author's words, be a "most popular scheme," and we hope, therefore, that he may soon have the opportunity in a new edition of showing us how to make it a workable one.

The Colliery Manager's Handbook. By CALEB PAMELY. Third Edition. Medium 8vo, pp. 848, with 648 illustrations. London: Crosby Lockwood and Co., 1896.

IN its new form this work has been enlarged by about two hundred pages, considerable additions having been made to the chapters on shaft-sinking, surface railways, surveying and planning, and safety lamps. In the chapter on coal mine gases and ventilation, the introductory part dealing with the chemical and physical properties of gases has been greatly improved, it having been re-written by Dr. Frank Clowes, of University College, Nottingham, and the geological part has been revised by Mr. F. W. Riedler, who has replaced the diagrams in the earlier pages of the former edition by new ones. The result of the co-operation in these two instances has been so satisfactory as to lead to the wish that the same principle of expert assistance had been followed in other sections of the volume. As it is, the additions seem to have been made with the principal purpose of increasing the size of the volume, when judicious concentration would have been more valuable. What may be considered to be the principal section—namely, that on coal working—seems to be reproduced without alteration, and there is substantially nothing given about the use of compressed air or other methods of transferring power from the surface to underground workings. The chapter on safety lamps has been extended to ninety-five pages, or rather more than a tenth part of the whole book, which seems excessive, considering that the whole of the mechanical details of centrifugal fans are compressed into about thirty lines, and no space has been found for such important subjects as screening and coal washing. In the preface the author calls attention to the account of the Gobert modification of the Poetsch process of sinking through watery ground by freezing the strata, which is now published for the first time in England. This differs from the original method in dispensing with the use of calcium chloride solution as an intermediate agent, the freezing being done direct by allowing liquefied ammonia from the condenser to evaporate in the circulating tubes around the site of the pit. This account is extremely interesting and well illustrated, but no details are given of the practical results obtained by the method. There might be a better utilisation of the heat expended by doing away with the intermediate fluid, but in the absence of evidence to the contrary, it may be doubted whether the work of freezing would go on as regularly. The main point to be regarded is regularity in working the compressor, and this is more likely to be attained when it draws its supply from an evaporator near at hand than when it has to depend upon evaporation going on at a number of different points in a circuit of pipes, which may, as in a recently described case, be more than two miles long. In the case in question, the sinking of the Vicq pits at Anzin, the primary cooling was done with about 14 cwt. of ammonia, which was evaporated, compressed, and liquefied once in every twenty-five minutes, with a range in temperature of 62 deg. Fah., while the freezing employed 77 tons of brine, containing 25 tons of calcium chloride, whose temperature in making the round from the refrigerator through the freezing tubes and back was only raised about 4·7 deg. The parts played by the two fluids are so dissimilar that it is difficult to see how in such a case the brine could be safely discarded. We should, however, be glad to have more information on this point.

Weather and Disease; A Curve History of their Variations in Recent Years. By ALEX. B. MACDOWALL, M.A., F.R. Met. S. London: The Graphotone Company, 1, Maclean's-buildings, E.C. Price 2s. 6d. 1895.

THE relation that subsists between variation in health and variation in weather is probably not personally ascertained by more than a very few, if any, people living. That changes of considerable magnitude in the weather are accompanied by effects more or less notable, though not always the same in the health of most people, is, perhaps, undoubted, and some attempts have been made to trace relation between meteorology and zymotic disease; but this relation is chiefly followed in connection with large numbers of people and death rates. The comparison of these death-rate fluctuations, and variations in rainfall and temperature, involve a good deal of trouble, or, at all events, of care, and the interpretation of the meaning of the variations and their co-relation is at any time a mental exercise, which is greatly simplified by the graphic method adopted by Mr. MacDowall in this little book, and also in a book previously published by him, showing by curves the changes in the history of certain parts of the History of Ireland. In the book before us there are thirty-six diagrams giving the fluctuations over greater or less periods in the temperature, rainfall, dryness, frosts, spells of hot and cold weather, sun spots and thunderstorms, early and late seasons.

Sixteen of the diagrams show the rise and fall of the most prevalent diseases, the rise of some and the decadence of others. The curves include the whole variation through short periods within each of a number of years, and a heavier line curve shows the mean variation, so that the effect over long periods is shown at a glance. In the short discussion which accompanies each curve, in several cases connecting the disease curves with the meteorological curves, Mr. MacDowall's book will be found of interest to a great many readers, and an extension of it or his curves might usefully be made in which the relation between both sets of observations might be graphically shown. The abscissæ might be easily co-related, and the ordinates might be arranged so that the curve relations might be read off by means of two or more ordinate scales.

SHORT NOTICE.

Practical Hydraulics for the use of Waterworks, Sanitary, Agricultural, Drainage, Irrigation, Inland Navigation, Mining, Railway, Harbour, and River Engineers. Part No. I. Kutter's Formula Simplified, for the Easy and Rapid Calculations of the Discharge of Rivers, Canals, Channels, Drains, Culverts, Sewers, and Pipes. By J. W. H. Hullet, C.E., Adelaide. Hussey and Gillingham. 1896. Price 5s.—This is a once-folded card carrying the several expressions of Kutter's formulæ for velocity, discharge, and diameter or dimensions, with tables of coefficients for different surfaces. Kutter's formulæ are given as slightly modified, and with modified coefficients giving correct results where Kutter's are correct, and slightly simpler formulæ for use when a maximum error of 2 per cent. is unimportant. The collection of formulæ, examples, and coefficients is a useful one, and the author, who is in the department of the engineer-in-chief of the Government of South Australia, gives formulæ for irregular channels, and intends to supplement the card now published by another giving special formulæ for different branches of hydraulics.

BOOKS RECEIVED.

British Industries and Foreign Competition. By A. Williamson. London: Simpkin, Marshall, Hamilton, Kent, and Co., Ld. 1894.

A New View of the Origin of Dalton's Atomic Theory. A Contribution to Chemical History. By Henry E. Roscoe and Arthur Horten. London: Macmillan and Co. 1896. Price 6s. net.

The Local Government Annual. An Official Directory. 1896. Edited by S. Edgecumbe-Rogers. Fifth year of publication. Price 1s. 6d. London: *The Local Government Journal* Office.

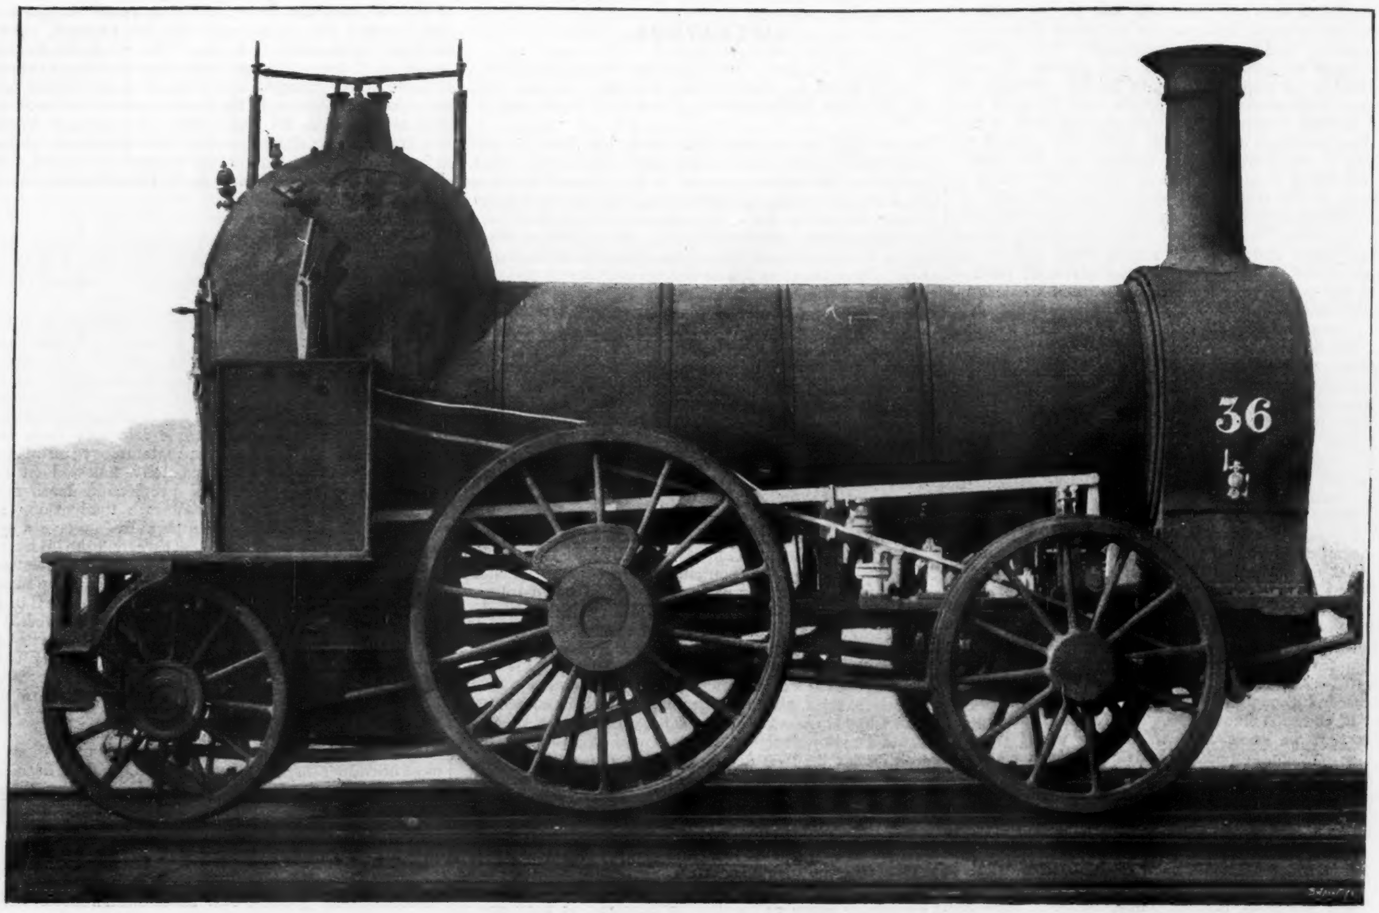
The Local Government (England and Wales) Bill, 1893. *Abstract of Clauses of the Bill, with Full Index.* Reprinted from the *Local Government Journal.* London: S. Edgecumbe-Rogers, the *Local Government Journal* Office. Price 1d.

The Steam Engine considered as a Thermo-dynamic Machine. A Treatise on the Thermo-dynamic Efficiency of Steam Engines. Illustrated by diagrams, tables, and examples from practice. By James H. Cotterill, M.A., F.R.S. Third edition. Revised. London: E. and F. N. Spon. 1896.

DEATH OF MR. THOMAS GALLOW, MECHANICAL ENGINEER AND INVENTOR.—In the death of Mr. Thomas Gallow, 13, Lilly Hill-terrace, Edinburgh, the mechanical world has lost one of its sons of inventive genius. He died on New Year's Day, at the age of fifty-nine, after an illness of some months of great pain and suffering. He was buried on Saturday, the 4th, in Rosebank Cemetery. His body was followed to his last resting-place by many friends and admirers of his genius. Mr. Gallow was the patentee of several useful mechanical inventions, which brought him little monetary reward. For the long period of twenty-eight years he occupied the responsible position of mechanical engineer to the Commissioners for the Harbour and Docks of Leith. In this capacity he made many valuable additions and improvements to the dock machinery. With Mr. Chapman, of Messrs. Hawthorne and Co., of Leith, he was joint patentee of a simple form of hydraulic capstan, used instead of horses for the haulage of coal to the hydraulic hoists. This form of hydraulic capstan has been in use at the docks for several years, and has proved an entire success.

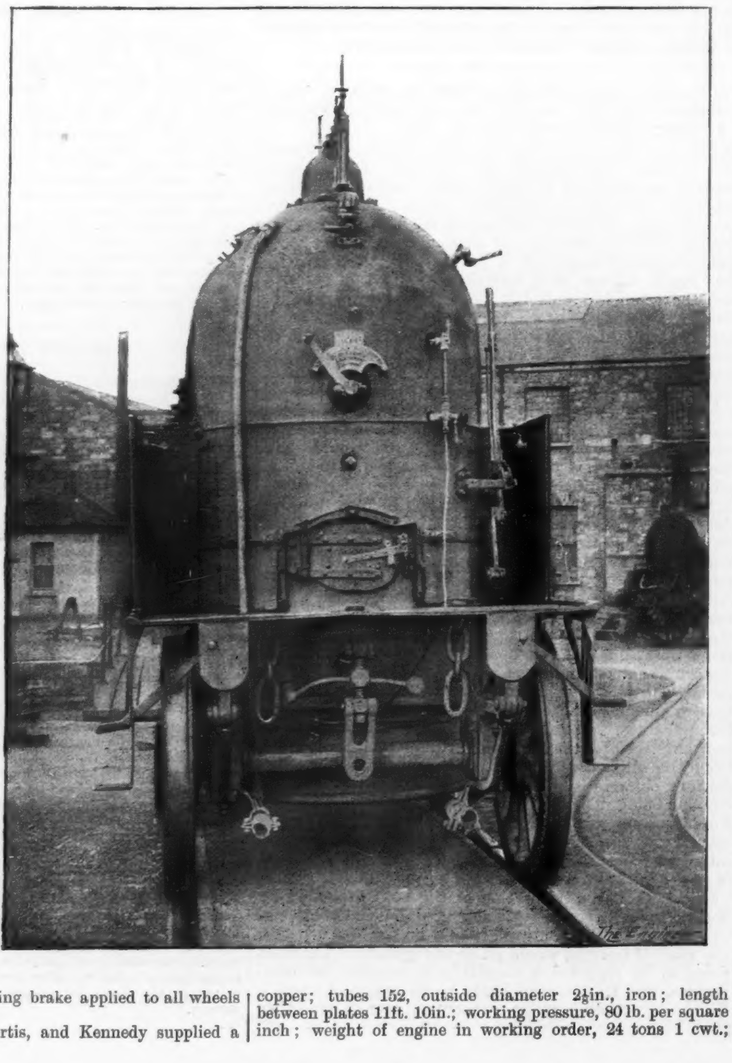
PASSENGER LOCOMOTIVE—GREAT SOUTHERN AND WESTERN RAILWAY, 1847

MESSRS. BURY, CURTIS, AND KENNEDY, ENGINEERS



PASSENGER ENGINE, GREAT SOUTHERN AND WESTERN RAILWAY, 1847.

In our last impression we illustrated the Jenny Lind, and now, through the courtesy of Mr. Ivatt, we are enabled to illustrate one of the best engines ever built by Messrs. Bury, Curtis, and Kennedy. The photograph was taken nearly ten years ago, after the engine had fallen into decrepitude, and gives no adequate idea of its finish and excellence of workmanship when new. The engines on the Great Southern and Western Railway were always very well kept, and the copper dome and brass-work were polished, and the paint and varnish excellent.



Unfortunately there is no complete drawing of the engine in existence. That which we have reproduced is much dilapidated, but enough remains to show the bar frame. The engine was put on the line in 1847 and worked up to 1872, running 345,163 miles in that time, or 13,800 miles per annum. The permanent way consisted of flange ⊓ rails weighing 90 lb. to the yard.

The engine was No. 36, and its dimensions as follows:—Wheels, six, single, diameter leading 4ft. 2in., driving 5ft. 8in., trailing 3ft. 8in.; wheel base, front 6ft. 11in., hind 6ft. 2in., total, 13ft. 1½in.; axle-box bearings inside; inside cylinders, 14in. by 20in.; copper fire-box, length 3ft. 3in.—inside—breadth 4ft., height above grate 4ft. 3in.; iron tubes, 119 outside diameter 2⅛in., length between plates 10ft. 8½in. tires, steel, made at Leeds; weight of engine in working order, 19 tons 10 cwt. Tender: Capacity of tank 1344 gallons; number of wheels, four; hanging brake applied to all wheels both sides; tires iron.

In 1848 Messrs. Bury, Curtis, and Kennedy supplied a goods engine, No. 105, of the following dimensions:—Wheels, six four-coupled; diameter of wheels, driving and leading 5ft., trailing wheel 3ft.; distance of centres, front 8ft., hind 6ft. 8in.; axle bearings inside; cylinders 16 by 24—inside—fire-box, length 4ft. 3in., breadth 4ft. 4in., height 4ft. 7in., copper; tubes 152, outside diameter 2¼in., iron; length between plates 11ft. 10in.; working pressure, 80 lb. per square inch; weight of engine in working order, 24 tons 1 cwt.; tires, iron. Tender: Capacity of tank, 1344 gallons; number of wheels, four; brake applied to all wheels both sides; iron tires.

On page 66 we give detailed drawings of the crank axle and driving-wheels. The hubs were of cast iron, the forged centre with split spoke ends being put in the mould and the cast iron run round it. These wheels were very successful, and it is worth notice that balance weights were used as far back as 1847, and probably long before that date, by Bury.

THE MANCHESTER SHIP CANAL TRAFFIC.

Tables showing approximately the traffic over the Ship Canal for 1895 have been issued, and although the statement does not come up to the expectations of the most sanguine of its advocates, still the amount is substantial, and gives good hope of continued improvement. At length the great waterway is becoming equipped in various ways to conduct traffic in a manner to satisfy the needs of shipowners and others. The connection with the London and North-Western Railway Company is made by the branch railway from Eccles, and in addition to the transit sheds on the quays, large warehouses are provided for the storage of goods. The Manchester Corporation have their cold air stores in active use.

During 1895 and 1894 the traffic and receipts are given as follows:—

	1895. Tons.	1894. Tons.	Increase. Tons.
Seagoing traffic	1,087,443	686,158	401,285
Barge traffic	271,432	239,501	31,931
Total	1,358,875	925,659	433,216
	Receipts.		
	£	£	£
Seagoing traffic	120,586	76,969	43,617
Barge traffic	5,073	3,636	1,437
Passengers	1,750	6,865	* 5,115
Rents and sundries ..	9,350	7,186	2,164
Total	136,759	94,656	42,103

* Decrease.

As compared with the early days of the Suez Canal the increase is not discouraging. In 1870 the gross tonnage by way of Suez was 1,142,200 tons; in 1869, 654,915 tons; increase, 487,285 tons.

Royal School of Mines.—The twenty-third annual dinner of the Old Students of the Royal School of Mines will take place at seven o'clock on Friday, January 24th, 1896, at the Criterion Restaurant. The chair will be taken by Mr. A. G. Charleton, Assoc. R.S.M., Member of the Council of the Institute of Mining and Metallurgy.

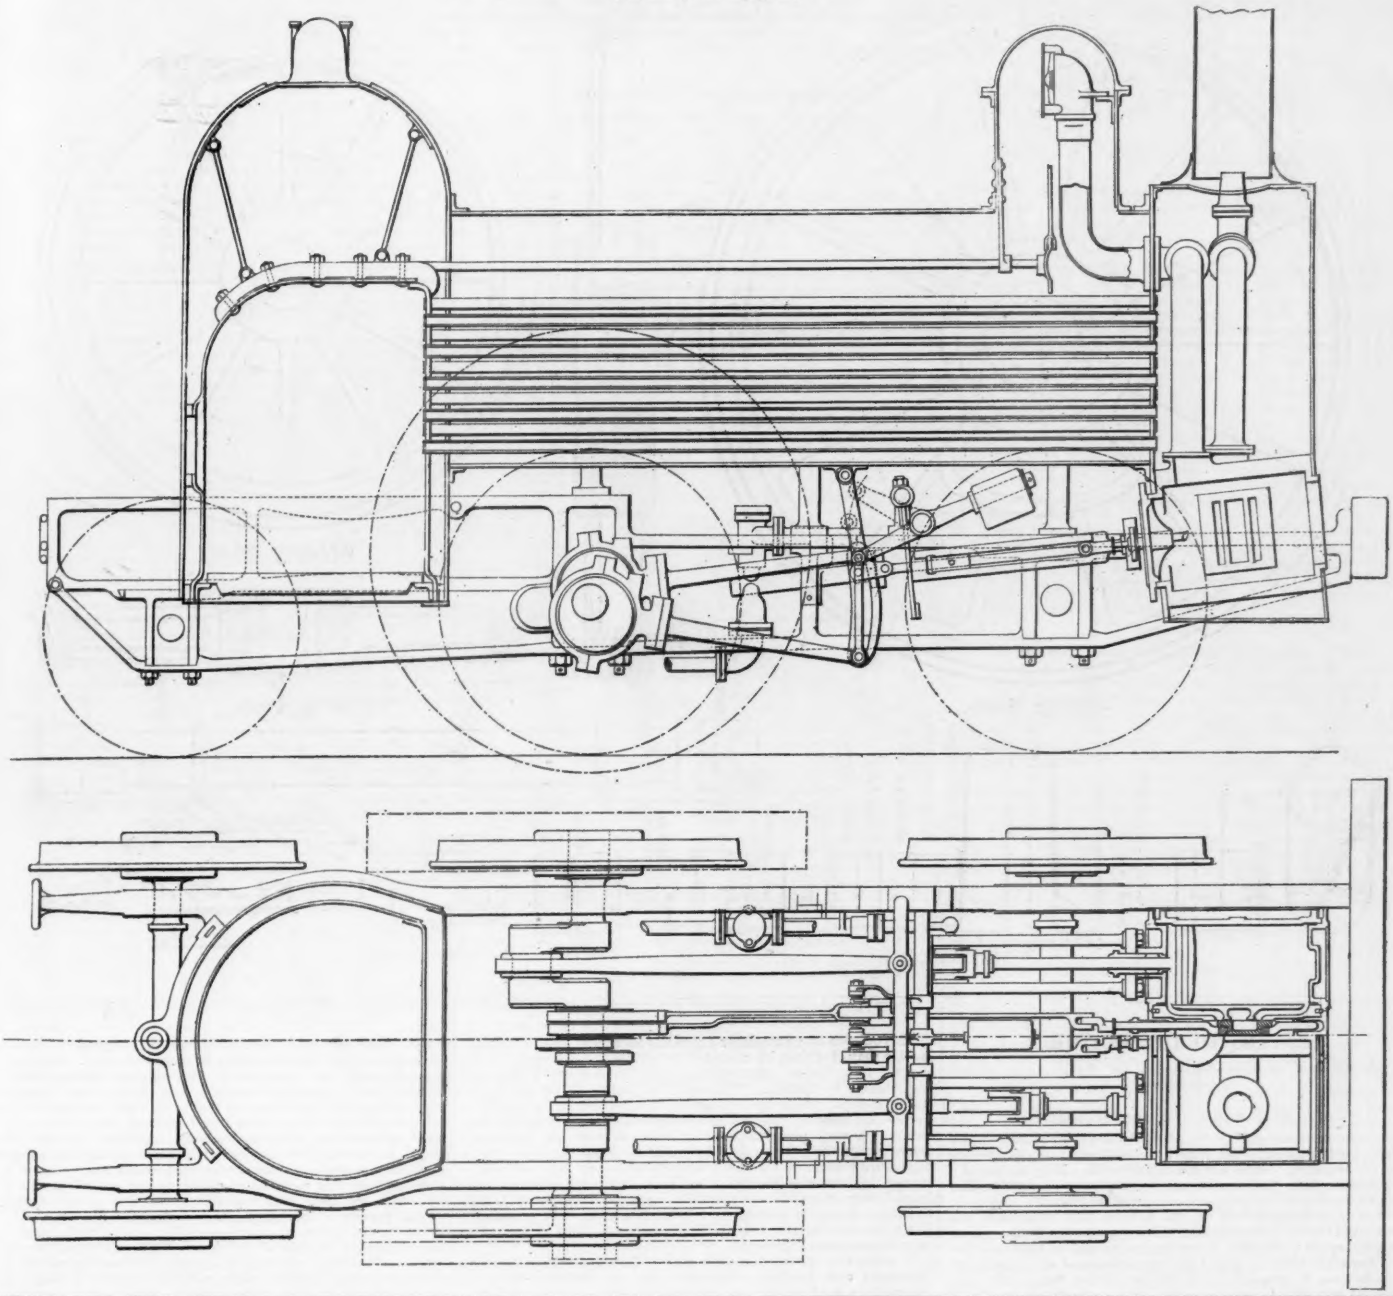
Rope Traction.—The particulars of the London Tramway Company's Brixton-hill rope will be read with interest by those who have the adoption of the rope system of haulage under consideration:—

Length	30,000ft
Size when new	3⅝in. cir. full
Worn down to	3¼in. cir.
Put to work	July 9th, 1893
Taken off	November 9th, 1895,
Worked	853 days
Speed	8 miles per hour
Time	18 hours per day
Total rope miles	123,120
Total car miles	1,791,293
Cost per car mile	·1608 pence
Total passengers carried	24,232,699
Cost per passenger	·001188 pence

This rope was made of Cradock's improved patent crucible stee. Lang's patent lay.

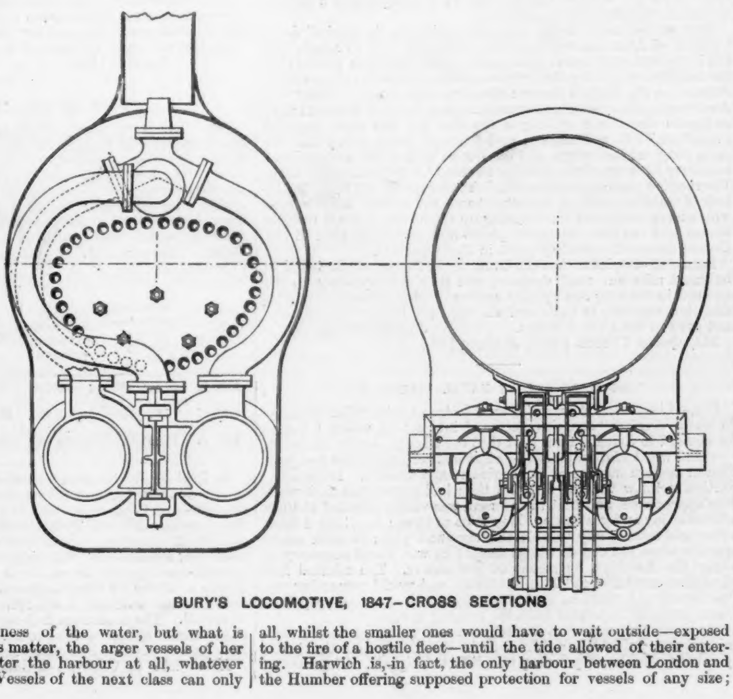
PASSENGER ENGINE, GREAT SOUTHERN AND WESTERN RAILWAY, 1847

(*For description see page* 64)



THE DEEPENING OF HARWICH HARBOUR.

THE condition of Harwich Harbour has been the subject of frequent complaints to the Harwich Conservancy Board, and has also been repeatedly brought under the notice of the directors of the Great Eastern Railway, who are interested in the subject on account of their services from that port to the Hook of Holland and Antwerp. It seems that on the "Gristle" shoal, lying between the Guard and North Shelf Buoys, there is as little as 14ft. at low water ordinary spring tides, and on the "Glutton" shoal, extending from the North Shelf Buoy to the North Cliff Buoy, there are several patches on which there is but the same depth of water; but when, at spring tides there is a continuation of south-westerly winds, the water falls more than a foot below the figures shown on the Admiralty charts. It is true there is a narrow channel between the "Gristle" and the "Guard" shoals with 20ft. water, and also a channel between the "Glutton" shoal and Felixstowe beach with 19ft. at low water; but this is only narrow, and there are no lights to lead vessels through. This channel, therefore, cannot be used at night, nor can it often be used by day, as it is almost invariably blocked up with vessels at anchor, so that it is impossible to get into the deep water. The result of all this is that not only do the four Great Eastern vessels of the new type, which draw about 15ft. 6in., frequently touch the ground at low tide, owing to the shallowness of the water, but what is regarded as a much more serious matter, the larger vessels of her Majesty's Navy cannot now enter the harbour at all, whatever may be the state of the tide. Vessels of the next class can only enter or leave the harbour at the time of high water, and the present guardship, the Mersey, which may be included in the third-class, with a draught of about 19ft. 6in., can enter or leave the harbour only at half tide. Should, therefore, one or more of our ironclads sustain any serious damage in time of war, and try to make the harbour, the larger type would not be able to enter at all, whilst the smaller ones would have to wait outside—exposed to the fire of a hostile fleet—until the tide allowed of their entering. Harwich is, in fact, the only harbour between London and the Humber offering supposed protection for vessels of any size; but although during the last twenty-five or thirty years the military authorities have spent thousands of pounds on Harwich and neighbourhood, and although the harbour itself is now strongly guarded by forts and batteries mounted with heavy guns, and garrisoned by detachments of artillery and marine-artillery, nothing has been spent during the whole of this time in rendering the harbour itself more accessible to her Majesty's ships.

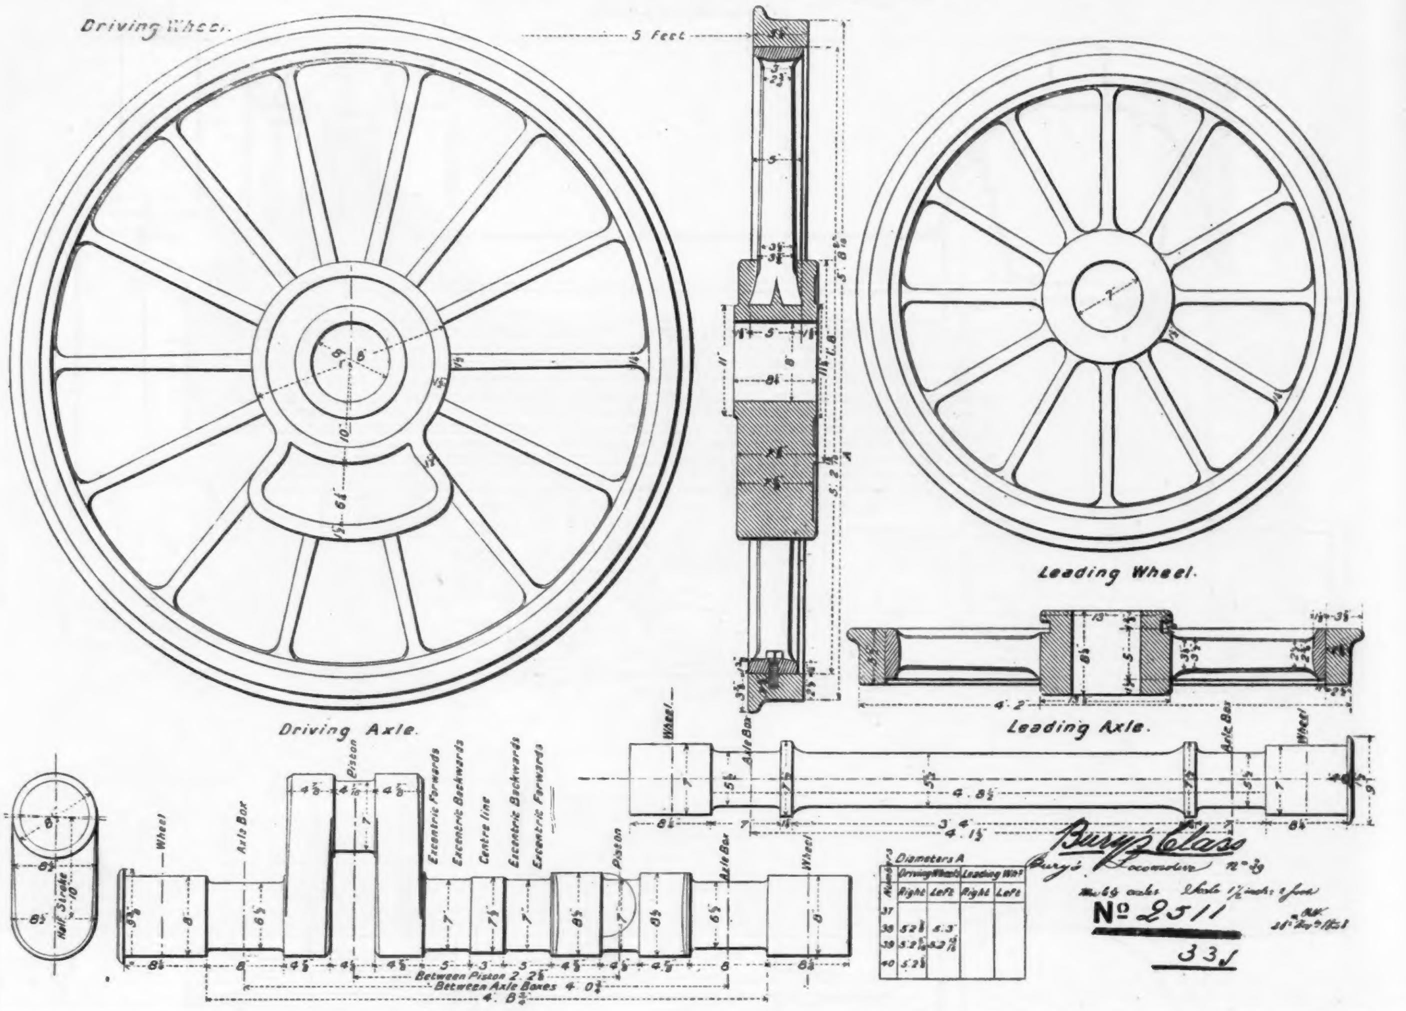


BURY'S LOCOMOTIVE, 1847—CROSS SECTIONS

The attention of the Admiralty has been called to the matter, and a reply has been received stating that: "Sounding has been carried out at Harwich at frequent intervals during the last ten years, and the variations discovered last spring were much less than usual. So far as the soundings made at the request of the Board of Trade are concerned, there is no ground for apprehension that the harbour is 'silting up.'" It is, however, urged that the real question at issue is not whether the harbour is becoming still shallower, but whether it should not be dredged sufficiently deep to allow not only of passenger ships navigating it without touching the ground, but also of the large vessels of our Navy being able to enter in case of need. This latter point, it is contended, says the *Times*, should be regarded as having an important bearing on the question of national defence.

THE INDEX MAP OF THE GEOLOGICAL SURVEY.—A new departure has recently been made by the Government with a view to popularising the work of the Geological Survey, by supplementing the maps which have hitherto been published on the scale of 1in., and in part on that of 6in. to a mile, with a smaller one on ¼in. to the mile scale, containing as much of the detail of the 1in. map as is likely to be generally useful to travellers and tourists. Several sheets of this map have been prepared and coloured by hand, according to the system adopted for the larger scales; but this, no doubt the best method, is practically prohibitory as regards price. The cost of colouring a double-elephant sheet with an average amount of detail, would make it necessary to charge 10s. 6d. to avoid loss. An experiment has therefore been made by the Stationery-office of printing in colours one of the sheets—No. 12, including the South-East of England, south of Cambridge and Orfordness down to Battle, and westward to Blisworth and Petersfield—which can be sold for 2s. 6d. a copy. The colour-printing has been done by Messrs. Wyman and Co. and is extremely good, leaving little to be desired when compared with the hand-coloured copies. The sheet selected is well adapted to test the capabilities of the method, as it contains no less than nineteen different formations, from the lias upwards to the Suffolk, all of which are indicated by flat tints without dots or cross-hatchings, the general scheme of colour being similar to that of the larger maps. Should the experimental map be successful, the Stationery-office propose to produce the other sheets of the series in the same manner, so that we hope that it may meet with a ready sale.

BURY'S PASSENGER ENGINE, 1847—DETAILS OF DRIVING AXLE AND WHEELS



LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

BULLHEAD RAILS AND FLANGE RAILS.

SIR,—In your issue of 27th ult., Mr. Tratman, in a latter on this subject, further defends the American preference for the flanged section. He says, "Rails are intended for the rolling surface of a track construction, and should not be considered as independent structures acting as bridge spans supported on piers."

I have never suggested that a rail is to be thus considered, nor even that it should be compared with a continuous bridge girder of several spans; and such a comparison would be fallacious, because the alterations of levels due to subsidence of sleepers are altogether out of proportion—in relation to the spans—with any variations met with in bridge piers. But, curiously enough, as it seems to me, some such assumption must be involved before we could regard the provision of a "rolling surface" as the main purpose of a rail.

If the supports were absolutely fixed in level, we might, by reducing their distances, increase the effective strength and stiffness of the rail indefinitely; so that, if the sleepers were placed close together, the rail would not require any appreciable stiffness, and need only be a wear-resisting strip. That such reasoning would be quite inapplicable to a railway, is sufficiently evident from practice in the United States, where experience has dictated the use of the heaviest rails yet made, although they rest on sleepers spaced more closely than usual in any other country. My contention has been that stiffness for the purpose of distributing a concentrated load over a considerable length of track, and reducing vertical curvature, is one of the most essential functions of a rail. Deficiency in rail stiffness cannot be compensated by close sleepering, and this, I think, is shown in American practice by an unnecessary expenditure of material, owing to the section of rail adopted.

Of course, stiffness is a quality distinct from strength under static stress; the one depending upon the moment of inertia, and the other upon the moment of resistance of the section; and it is quite possible that with two rails of the same weight, one may have less strength but greater stiffness than the other. Under fast traffic, I suggest that with two rails of equal static resistance, the stiffer one would be effectively stronger owing to its greater radius of curvature under the advancing load, and that therefore, important as adequate stiffness is in all cases, increasing speeds render it more especially so at the present time for the sake of both road and rolling stock.

A bullhead can always be made stiffer than a flange rail of the same weight without altering the head or decreasing the strength, and, as far as I have been able to find, the only argument in favour of the latter now is saving in initial cost of track. As regards that point I am enabled, by the courtesy of Mr. Tratman in a personal communication, to quote Mr. Sandberg's opinion as follows:—"It would, therefore, be better to give up the plan of laying the rail flange direct on the tie, and to adopt a steel tie-plate of sufficient surface, or equal to that of the cast iron chair, nearly 100 square inches, say 12in. by 8in. and ½in. thick, so as not to bend it, and fasten the same to the tie with three fang-bolts, wood screws or spikes, using clips and steel keys for fixing the rail to the base plate." That rather suggests an emergency expedient, but to continue quotations: "By this means it might be possible to obtain an equally good and safe track with flange rails as with the English bullhead type of rail, and at somewhat less cost. . . . As it would be useless to try and introduce the English type of track in those countries where flange rails are already adopted, the only way to obtain an equally safe and strong road for heavy traffic as on the English lines seems to be to strengthen those by the adoption of the Goliath rail with steel tie-plates, but to let everyone keep to his section of rail."

This opinion of an engineer especially identified with the flange section may, I think, be accepted as strong confirmation of the views I have before expressed in your columns, but it goes one important step further. "It would be useless to try and introduce" a type, which by implication is admitted to be superior, because an inferior type was adopted at the outset. I submit that this has a very practical bearing in relation to Mr. Tratman's remarks regarding Colonial development by cheap railways. When the future welfare of a growing country is kept in view, much may be said in favour of "building for posterity" as contrasted with hand-to-mouth expediency; and the engineer to whose lot it falls to initiate a type of permanent way which is likely to be permanent has in his control more far-reaching power for good or evil than may be generally supposed.

It is not the rail section only that is involved. In comparing American and English permanent way, the different types of locomotives used in the two countries should not be overlooked. With smaller wheels and shorter distances between their axles, an American locomotive is statically easier on the road, weight for weight, than an English one; the frame and springs serving to perform part of the duty thrown upon the rail here. This suggests the following rather curious coincidence. We find in the United States extremely heavy rails, sleepers placed at very short intervals, and locomotives with very short distances between their axles; and a possible cause for each one of these peculiarities might, by *a priori* reasoning, be found in the adoption of a form of rail inherently deficient in stiffness.

That we owe much to the experience gained in the gradual development of American railways I should be the first to admit, and the introduction of cars of American type on our roads proves that the Britisher is not hopelessly conservative, but such cars are more at home on the English than on the American track. That "the American track is probably more stable than the best English track, owing to the closer spacing of the ties and the more frequent fastenings," I do not believe, and I should prefer to say that the more frequent fastenings, and the ties to hold them, are rendered necessary by want of the stability afforded by the chairs used here. The running performances on English railways do not indicate any lack of stability, and, on the other hand, the various contrivances which have been tried for strutting up the heads of flange rails on curves, and the more recent tie plates and fang bolts used in the United States, do certainly point in that direction.

I am still of opinion that the track of the future will be found in bullhead rails on steel sleepers, and that the economy to be secured in the long run by that system must eventually secure its adoption, not only in India and the Colonies, but in this country, and even in the United States. JAMES WHITESTONE.

113, Queen Victoria-street, January 13th.

THE ENGINEER IN NAVAL WARFARE.

SIR,—Lieutenant Edwards' second lecture on the "The Engineer in Naval Warfare" contains matter of interest on which I beg to be allowed to touch. I am glad that the admiral—with his quick eye and wonderful judgment—had at last recognised the real position in modern warfare of the engineers and firemen. It is a satisfaction to know that at last the time had come when their work was appreciated, and that the admiral was visibly affected at their cheers of joy and gratitude. May it be so in our case! As I have often said before, why trouble the wires and pipes in such emergencies when you can do things direct? It was found necessary to steer the Brooklyn by means of her screws. The admiral had doubtless carefully read THE ENGINEER, and would remember my last letter, and what he could have done had reversing propellers been available, operated from the conning tower.

At times the seaman at the engine-room telegraph in the conning-tower pulled the lever a trifle too hard, and the index pointed to the line separating two different signals. The man on watch—with *his* quick eye and wonderful judgment—would have to decide quickly to which order he would respond. Just so! Before the fight was over one of the engineer officers fell in an apoplectic fit. And no wonder. Any doctor who understood engineering would say that the real cause of his death—he passed away in three months, glorified by a crown of martyrdom—was the want of means for direct action on the screws by *the* brain of the ship. In an action of this sort had the engineer not enough to look after in such a place under such conditions, without being troubled with this uncertain manipulation at second hand? Why, the waste of time and uncertainty of the present system at critical periods is enough to give the admiral "fits," too.

During the action the engines of the several ships were used intermittently not only at full speed, half speed, and at varying speeds of backing, but at progressing and decreasing speeds ahead. In order to obey quickly, valves will be suddenly opened. Starting up quickly will cause the boilers to foam, and if water gets in the line of steam piping there is going to be trouble. Why not avoid all this by means I have so frequently pointed out in your esteemed journal?

I pause for a reply from the men of "quick eye and wonderful judgment," especially as I have just received reports from the manufacturers, of the continued excellent working of reversing propellers, to the satisfaction of every owner of every installation. One of fairly large diameter has now been out two winters in one of the roughest seas round our coasts; and everywhere they have proved themselves trustworthy. This aid to easy manipulation and safety of the great ships of war ought to be used in our Navy.

39, Dagnall Park, Selhurst, S.E., ROBT. MCGLASSON,
January 11th. Hon. M.I.M.E.

FREE TRADE AND NO TRADE.

SIR,—The more deeply we study the course of prices, and the effects on our food supplies caused by the Repeal of the Corn-laws, the greater is our amazement at the extraordinary delusions which have so long existed in regard to what was in reality the most disastrous measure ever passed by the Legislature of this country. To enable your readers to see at a glance what were the results so directly the reverse of the promises held out, I have compiled the following table. The figures of home production are taken from Messrs. Lawes and J. H. Gilbert's table in the *Field*, 12th February, 1887:—

Years.	Average yearly imports of wheat and flour, qrs.	Average yearly home production, quarters.	Total quarters.	Per head of population, lb.	Average yearly prices per quarter.
1852-59	4,767,803	14,435,799	19,203,582	326	57s.
1860-67	7,977,632	13,300,296	21,286,879	347	50s. 7d.
1868-75	10,801,453	12,684,765	23,486,219	357	53s. 11d.

In 1842 Sir Robert Peel estimated the annual home production of wheat at twenty-two million quarters—see *Annual Register*, 1842, page 38—and Cobden, in 1843, at twenty millions. It will be seen that between 1852 and 1859 it had fallen to 14,435,779, a decline of 7,564,221 quarters. From 1842-46 the import averaged, yearly, 1,647,688, against 4,767,803, an increase of 3,120,115 quarters; or, notwithstanding the increase in population—1,014,823—a less supply available for consumption of 4,444,106 quarters, and if we take Cobden's estimate, 2,444,106. Such were the blessed results of repeal. The consumers had to pay 57s., or about £7,000,000 more than as shown by the prices ruling before repeal, they would have had to pay had Protection not been withdrawn.

If we add to Cobden's estimate of 20 millions, the 982,287 quarters we imported in 1843, we get 370 lb. per head, or 27 lb. more than the average of the 24 years, 1852-75. During 1843-45, when wheat was subject to a duty of 20s. per quarter, the price averaged 50s. 8d., or actually 6s. 4d. less than from 1852-59. From 1833-37, when the duty was 34s. 8d., the price averaged 48s. 5d., or 8s. 7d. less. These figures, which any one can verify for himself by referring to the "statistical abstracts," simply tear into shreds the fictions about the miseries inflicted on the people by the corn duties, so industriously circulated for political purposes, and incontestably prove, that not only were these duties not paid by the people, but that, had they never existed, bread would have been dearer.

And there are actually people among us, thanks to Cobden Club misrepresentations, who still cling to the belief that our prosperity after 1850 was caused by the abolition of the Corn Laws in 1849, for achieving which Richard Cobden has been elevated to the position of a demi-god; a man, as Mr. Morley says, "who had found out a momentous secret," and for which he was presented with a national testimonial of £75,000! And in the face of our greatest industry ruined, and the others having to struggle for their very existence against this cruel foreign competition, through his instrumentality, the Cobden Club has actually deemed the present a fitting time to publish and circulate gratuitously throughout the country a short memoir of their false prophet, which, for a travesty of truth, could hardly be excelled.

I should have thought the lesson these figures teach would have been sufficient for all time, but, as if the nation had not yet had enough of the squandering of its revenue, Mr. Gladstone's Government in 1869 must needs lay its hands on the "last rag of Protection" left to the unfortunate British farmer—the shilling registration fee on corn. No one complained of it, not even Cobden. It then yielded a revenue of £900,000 per annum. Since its abolition we have to end of 1895 imported 799,614,154 quarters of grain, which would have given £39,980,707 to the Exchequer, or if we add compound interest at 3 per cent.—which I have taken the trouble to calculate — no less a sum than £56,609,940! Here again the consumer did not benefit, for the price, which between 1863 and 1869 averaged 50s. 6d., actually averaged during 1870-76 52s. 4d. Who then benefited? If not the foreigner, perhaps the Cobden Club will tell us who did. Let it be borne in mind that this revenue, so recklessly thrown away, was not a remission of, but inasmuch as it had to be made good from other sources, which the foreigner wholly escaped, an addition to taxation. Mr. Morley in his life of Cobden says:—"History shows that Cobden was amply justified in laying down the principle that the affairs of a nation come under the same laws of common sense and homely wisdom which govern the prosperity of a private concern."

Will Mr. Morley, or indeed any one out of Bedlam contend that the abolition of that shilling fee was an act of common sense or homely wisdom? If such were the principles on which Cobden conducted his business of calico printing, little wonder he succeeded in landing it in such a state of insolvency; it had, after a short career of six years, to be finally wound up, and that thereafter he confined himself to the more profitable occupation of agitation. The following table shows how rapid has been the decline of wheat cultivation, and the increase on the imports of wheat and flour since 1870:—

Years.	Average yearly supplies of wheat and flour. Quadrennial periods.			Per head.	Prices.	
	Imports.	Home production.	Total.			
	quar.	quar.	quar.	lb.	s.	d.
1871—74	11,253,192	11,800,831	23,054,523	346	57	0
1875—78	13,686,966	10,842,287	24,529,253	356	42	7
1879—82	17,113,197	8,566,227	25,679,424	355	44	8
1883—86	17,504,607	9,402,287	26,906,894	358	35	3
1887—90	18,780,418	9,456,111	28,236,529	365	31	6
1891—94	22,008,346	7,459,712	29,468,058	369	28	4
1895	23,360,952	4,700,000	28,060,952	344	23	1

Past experience, at least prior to 1876, has shown that when the supply was 350 lb. per head the price was, as nearly as possible, 50s. Yet, with only 344 lb. available for 1895, it is only 23s. 1d., or 52 per cent. less. How is this possibly to be accounted for, save by the enormous gambling going on in wheat "futures"? If the high price of 57s. from 1871-4 does not seem to agree with the price having ruled about 50s. when the supply was 350 lb., we must bear in mind that in those years we exported considerable quantities to France, which, the exports of wheat and flour being as a rule trifling, I have not deducted. It is very significant that these gambling systems in wheat, cotton, wool, silver, &c., first began in the United States in 1876, and not in this country and Europe till 1883.

There was one lesson taught us by Cobden, of which we might with advantage avail ourselves, and until we do so I fear there is little hope of fiscal reform—that is the formation of a great league to demand protection for British industries. Why our agriculturists, manufacturers, and others whom it so deeply concerns, should sit calmly contemplating the ruin so rapidly approaching of their country's great industries is inexplicable, when they have the remedy in their own hands, namely—a return to Protection. When the working classes realise the great fact, that in the last twenty-one years—1875-95—our imports have amounted to £7904 millions, a half of which, if produced at home, would have added £1387 millions to their wages fund, instead of having been paid to foreign labour; while if only 10 per cent. of duties had been levied on the other half, our revenue would have benefited to the extent of £395 millions, they will make short work of a system by which they have been so enormously defrauded. A. WILLIAMSON.

15, Moray-place, Edinburgh,
January 14th.

STOREY'S DEAD WEIGHT SAFETY VALVES.

SIR,—The correction of Messrs. Isaac Storey and Sons in your issue of January 3rd as to the design of the arrangements of dead weight safety valves for kitchen boilers, illustrated in your article, might with advantage have gone a little further. As a matter of fact, neither of the safety valves illustrated in the article which appeared in THE ENGINEER for December 27th, page 646, is the design of Mr. Lavington E. Fletcher. The open dead weight safety valve—shown in Fig. 1 in your article—was designed and patented more than thirty years ago by Mr. Cowburn, of Manchester, and is commonly known as the Cowburn dead weight safety valve.

I am sending you by this post a small treatise on "Household Boiler Explosions," by a former engineer of the Manchester Steam Users' Association, in which full credit is given to the Association for its experiments on the effect of admission of water in red-hot boilers, and on page 24 of this book will be found an illustration in section of the valve, and the following paragraph, which accurately describes it:—"An adaptation of what is known as the 'Cowburn' Dead Weight Safety Valve has been very generally adapted for this purpose, and is probably the best that could be devised, as there are no spindles, levers, or joints to become deranged."

Mr. Fletcher first suggested the attachment of safety valves to kitchen boilers in his monthly report for January, 1865, and in his report for January and February, 1867, he gives an illustration of the Cowburn valve, and describes it as "a miniature adaptation of a valve in very satisfactory use on many of the large steam boilers under the inspection of the association." The open safety valve, as stated in your article, required the building in the chimney breast of a cast iron box, fitted with a door to protect it from the dirt, soot, &c. Mr. Hiller in his design of enclosed safety valve—patented on behalf of the National Boiler Insurance Company—makes use also of the Cowburn valve; but his design has the merit of covering up the valve itself and protecting it from damage, as well as providing a means of testing the valve, and allowing the water to be conducted away without nuisance, the whole being self-contained and merely requiring screwing all together in one fixing to the top of the boiler, &c.

Mr. Fletcher, I think, cannot have seen your article attributing the design of both valves to him, as one would think a gentleman of his position and standing would be the last to appropriate credit to himself to which he is not legitimately entitled.

January 14th. HONOUR TO WHOM HONOUR IS DUE.

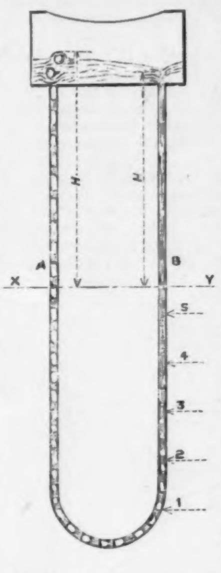
CIRCULATION IN WATER-TUBE BOILERS.

SIR,—The experiments of Mr. Yarrow related in your last week's issue are of the highest interest. But the deductions which can be drawn from the observed effects, without fully investigating their causes, will just throw a little more trouble on the controversy of circulation in water-tube boilers.

The most striking of the experiments carried out is the one numbered 7 in Mr. Yarrow's paper. Circulation maintained downwards in the return pipe, notwithstanding the whole of the heat being applied to it.

The photograph of the apparatus—Fig. 9, page 29—shows that in these extreme conditions heat only impinges on the lower half of the tube. The enclosed sketch represents how heads of water stand in this case. The upper half of the downcomer b is filled with a continuous liquid column, whilst the corresponding half of the branch a is filled with bubbles of steam alternating with water pistons. Motion is maintained by the difference of the heads h h.

This phenomenon can be produced, but with the peculiar conditions in arrangement of apparatus and starting of circulation realised by Mr. Yarrow. The downward flow in branch b will reverse if one or more burners be brought above line x y. The fact stated by Mr. Yarrow in his paper that such extreme conditions cannot be realised at atmospheric pressure is due to the different way in which the return tube was heated—as per Fig. 3, page 28. In experiment No. 6 the same phenomenon was produced at atmospheric pressure with air and cold water, and Fig. 8, page 29, shows that here inlet of air was applied to the lower part of the return branch.



Turning again to experiment No. 7, I will add that the slightest cause diminishing the volume of steam generated in the lower part of the downcomer will stop the flow and reverse circulation. Feed-water, colder and heavier, will immediately rush into the branch, stop ebullition, and when set up again the motion will be upward. It is even possible that the removal of the lagging which protects the small receiver on x—Fig. 9—would be sufficient to upset matters.

The conception and realisation of such an experiment is a most ingenious and skilful *tour de force*; but it has no analogy with what takes place in boilers where tubes are heated on their whole length, and where feed-water, or the inrush of cold air when firing troubles at any moment the thermic conditions of the steam generator.

As regards experiment No. 1, I often heated both branches of a U tube, with quite different results; decrease in circulation, and geyser action in both legs when equally heated. I tried yesterday to carry out Mr. Yarrow's experiment, but failed to maintain circulation. Probably this is due to the different mode of heating; my burners are not so wide apart, and I cannot light them at intervals one after the other. I am having my apparatus altered accordingly, in order to investigate the cause of this discrepancy. But whatever be the special conditions under which these experiments can be carried out, they clearly demonstrate one very important point: steam bubbles always follow the stream of water in which they are generated, whatever be its direction; they do not possess any entraining power, and by the sole fact of their presence cannot set an upward motion in surrounding water. For this demonstration the engineering world is greatly indebted to Mr. Yarrow. CH. BELLENS.

Paris, January 13th.

THE LINDE OXYGEN PROCESS.

SIR,—It is remarkable, I think, that up to the present no one has commented on the singular method of producing cheap oxygen devised by Dr. Linde, and described in your issue of October 4th. It is probable that in the first instance the scientific world received the announcement with incredulity. As, however, Professor Dewar has shown the Linde process at the Royal Institution, there is, of course, no room for doubt.

There is, however, much room for discussion as to the nature of the phenomena, and I hope that Col. Basevi, or someone else who has studied the motion of gases, will throw some much needed light on what takes place. First, we have what is known as "Joule's effect;" the cooling of an imperfect gas by passing forcibly through an orifice. Why is it cooled? The answer, that heat takes another form of energy, is only to substitute one puzzle for another. What other form of energy? Again, according to Lord Kelvin, hydrogen is heated not cooled. Why is hydrogen an exception to the general rule? But, in any case, the cooling produced is very small. I have seen no demonstration, mathematical or otherwise, of the relation between the cooling and total loss of heat. Is the Joule's effect necessary to the success of the operation? I think not. We are told that much of the success of the process is due to the first cooled air circulating round the pipe containing the second incoming quantity and reducing its temperature, but this can only be done by raising the temperature of the air just cooled. Of course the work can be done with a given volume of air, without any subsequent additions. Let us suppose that this air is divided into two portions, A and B. We are told that first A is cooled, then it cools B, then B cools A again, and then A cools B, and so on until liquid air is produced; but this is much the same as saying that a man standing in a bucket can lift himself.

I have been at some trouble to make calculations on the basis of the figures given in your impression for October 4th, and on no possible received thermodynamical hypothesis can I make the process work. I assume that the pressures and temperatures are not those which are really used. Is it too much to ask Dr. Linde for some further information? I presume that the discovery or invention has been fully protected by patents by this time, so that there is no longer need for reticence concerning a most valuable and interesting process. M. A.

Woodstock, January 13th.

EARLY LOCOMOTIVES.

SIR,—Mr. John Wilson, page 11, and Mr. G. A. Sekon, page 35, are both very much in error with reference to Mather, Dixon, and Co., and the Bath-street Works. I have sent to Liverpool to have the matter investigated, with the result that it is found that "Mather, Dixon, and Co. first appeared in the Liverpool directory for the year 1827, at their works, 23, Bath-street. They remained there till 1839, when they removed to Williams-street, Regents-road, Bootle, to the works known as Union Foundry. In 1843 the firm became Mather, Dixon, and Grantham, and ceased to exist at the close of 1844."

I have some of the old Mather Dixon drawings, dated Bath-street Works, 1838. It will therefore be seen that although Mr. Wilson may have a good memory, it is useless to rely on memory when it does not agree with official documents.

I am quite aware that Mr. Sekon, in his "History of the G.W.R.," has stated that "Some of those early engines were provided with a projector in front." But that does not alter the fact that no engine was ever built for the Great Western Railway with such a projector.

Full details have been given in THE ENGINEER, and also in my locomotive book, relating to the whole of the first twenty engines—Nos. 1 to 20—and the reason why no mention is made of the projector engines is simply because they were never built. Of course there may have been many designs, but that is not the point in question. CLEMENT E. STRETTON.

Leicester, January 13th.

SIR,—I find in my letter of the 6th inst., 9th line, an error. It should read, "I would not like to say that there was not a 10ft. spokeless locomotive driving wheel ever made."

The late discussion was on engines on rails, and it was proved that the Great Western Railway only had one 10ft. engine. There were many designs laid before the locomotive committee and Mr. Brunel. Steamboats on wheels was an old idea then, for in 1804 there was an "Eructor Amphibolis" built at Philadelphia for land and water, and it is recorded that it did actually work on both.

Has Mr. Sekon ever seen the books and papers of Messrs. Mather, Dixon, and Co., or has he seen the Liverpool Directories of 1827 to 1844? By the latter books, Messrs. Mather, Dixon, and Co. appear to have been at Bath-street from 1827 to 1839, when their address was altered to Williams-street, Regent-road, Bootle, namely, North Foundry. About 1843 the firm became known as Messrs. Mather, Dixon, and Grantham, which firm ceased to exist about 1845.

John Jones commenced business as a locomotive builder at Newton under the title of Jones and Potts, after the firm of Mather, Dixon, and Grantham broke up, where he was manager. I do certainly deny that there was any "steamboat" locomotives on the Great Western Railway. HENRY GREENLY.

Queen's Park, W. January 13th.

SIR,—In your interesting article on the Jenny Lind, passing reference is made to one of Bodmer's reciprocating locomotives. It has always appeared strange to me that none of the present—so-called—locomotive historians make mention of these curious engines. The South-Eastern Railway took over one when the joint committee was dissolved. This had 16in. cylinders and 30in. stroke; driving wheels 5ft. 6in. diameter; heating surface of fire-box 73 square feet; tubes 769 square feet; weight about 17½ tons. This engine was No. 123, and on its trial trip broke down and killed one of the attendants. This can hardly be the mishap to which you refer, as Lewes is not on the South-Eastern Railway. Another of these engines was constructed by Sharp Bros. and Co., in 1844, for the Sheffield and Manchester Railway. This had cylinders 14in. diameter, 20in stroke; driving wheels 5ft. diameter. A third—possibly the one that came to grief at Lewes—had outside cylinders 22in. diameter, 24in. stroke, 7ft. driving wheels, steam pressure 90 lb. to 100 lb. The real stroke was only half the above dimensions in each case. Bodmer was also famous for his method of working the steam expansively, about which little is said or perhaps known. G. A. SEKON.

January 13th.

PERMANENT WAY.

SIR,—The letter of "Sextus" states admirably the case against the American system of flanged rails; and all engineers who are acquainted with the English methods, and who have also watched the recent developments of American practice, must agree that the tendency is towards the use of chairs. But, curiously enough, "Sextus," while criticising Mr. Tratman's views, does not notice how that gentleman gives himself away in the latter part of his letter in THE ENGINEER of December 27th, where he describes a first-class track as composed of "flange rails of 80 lb. to 100 lb. per yard resting on steel plates on sixteen ties to eighteen ties per rail length of 30ft." The steel plate is the embryo chair, and suggests the adoption of the latter in due course. RAILBED.

Leeds, January 13th.

SLIDE VALVE FRICTION.

SIR,—Some years ago I carried out a series of experiments with a small double cylinder horizontal engine, working at 120 lb. pressure. It gave on the brake 28-horse power.

The slide valves were so made that they were relieved on the back of nearly all pressure, or worked like ordinary valves. The change could be very easily made in a few minutes.

I ran this engine several times under both conditions, taking indicator diagrams, the speed, load, &c., remaining always the same. The broad result was that about ·6 of a horse-power was required to work the unbalanced slide valves.

Lubrication was effected by a drop sight feed lubricator. The results obtained were exceedingly uniform. I arrived at the conclusion that about 5 per cent. of the indicated power of the engine was absorbed in working the slide valves. The engine made 180 revolutions per minute. The valves were large enough for cylinders another inch in diameter.

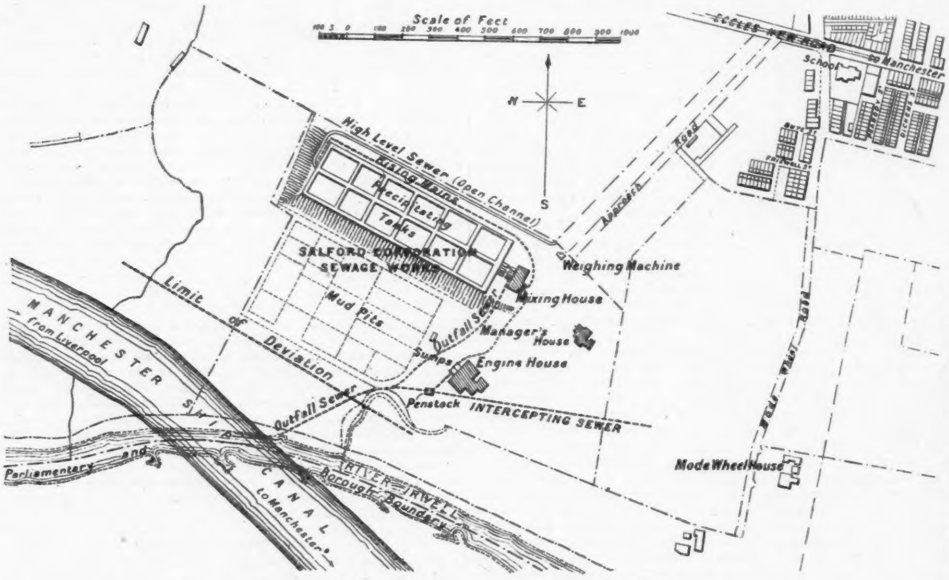
Paris, January 13th. FROTTOIR.

SHREWSBURY MAIN DRAINAGE.—On Tuesday, the 7th inst., an inquiry was held at the Town Hall, Shrewsbury, by Colonel Ducat, R.E., into the proposal of the Corporation to borrow the sum of £70,000 for the purpose of carrying out a main drainage scheme. The Town Clerk, Mr. Henry Clarke, appeared on behalf of the Corporation, and stated that the sewage of the borough now entered the river Severn at various points, and that the object of the scheme was to intercept the sewage from the river and to purify it. He also stated that the Corporation had had various schemes under their consideration during the past thirty years, and that an abortive attempt to carry out works had been made twenty-seven years ago, which works failed by reason of the extremely difficult nature of the ground met with. The scheme now before the Inspector had been prepared by Messrs. Taylor, Sons, and Crimp, of Great George-street, Westminster, with regard to which Mr. Santo Crimp and Mr. G. M. Taylor gave evidence to the effect that it was intended to construct intercepting sewers of a total length of about eleven miles, consisting mainly of brickwork and large cast iron pipes. As it was important to keep the sewers above the summer level of the Severn and to pump the sewage to the purification works, the site for the pumping station had been found in a central position in the town, to which the intercepting sewers gravitated from all directions. Here it was proposed to erect a pair of compound beam pumping engines to indicate 56-horse power, and to pump the sewage through a cast iron main, 21in. in diameter, to the head of the gravitation sewer, which is to have a carrying capacity of 7 million gallons a day. This outfall sewer, which is about 1½ miles in length, will discharge into settling tanks at the proposed farm. The tanks are to hold 600,000 gallons; and after the sewage has been chemically treated the clarified effluent is to be applied to land, of which 150 acres are available. The sludge is to be filter-pressed, and the works generally are designed in accordance with the most modern ideas. The scheme is intended for a population of about 40,000 persons, and is estimated to cost £70,000.

SEWAGE DISPOSAL AT SALFORD.

Salford has for the last twenty years at least been very much troubled on the question of sewage treatment and disposal. As conservator of the watershed of the river Irwell, she early set a good example to her neighbours and rivals in the valleys of South-East Lancashire by constructing, at great cost, very extensive plant for the pumping and chemical treatment of something like nine million gallons of sewage per diem. These works, including a duplicate range of large concrete tanks, were carried out by the late Mr. Arthur Jacob, who was at that time the borough engineer and surveyor, and were formally opened in the summer of 1881. Up to that time the lime precipitant was looked upon as the acme of perfection in all such cases, and the Salford works were accordingly laid out for this process; though Mr. Jacob, with true intuition, constructed his tanks at such a level as to command the ordinary ground level for subsequent filtration by gravitation if found desirable. If our more advanced knowledge and more scientific schemes of to-day lead us to modify these works, let us not condemn those who designed and authorised the erection of the existing works, but rather admire the public spirit which prompted them to undertake so heavy a duty, and practically without guide to attempt a solution of a question which many public authorities have persistently shirked even down to the present moment. There is no doubt that Salford has done far more towards the ultimate purification of the Irwell waters than is generally realised. At the same time it must frankly be admitted that the works, as originally designed, were not a success, according to modern requirements, and did not yield an effluent which could with satisfaction be discharged into the Ship Canal.

For the last six years the engineer and the responsible committee of the Corporation have been conducting a series of large scale experiments; and here again we note the public spirit of the Royal Borough, for these trials have been watched with keen interest by the whole of the municipal engineers of the kingdom. In all some thirty different schemes have been tested and watched at Mode Wheel, and the results of these have been carefully noted from time to time. Of these thirty, two were singled out as being the most satisfactory, and in 1892 tenders were received from these respective patentees or promoters. Either company was prepared to treat the whole flow of sewage, as delivered from the Corporation pumping station, for a sum of £12,000 per annum, on condition that the Corporation would purchase their plant at the expiration of twenty years. These offers, however, fell through, and the present borough engineer—Mr. Joseph Corbett—now reports to his committee that by an expenditure of £50,718 on alterations and extensions to the works, he can efficiently treat the whole flow at a cost of £6870 a year—this, of course, in addition to the cost of pumping the crude sewage, and carrying the sludge to sea by steamers, as at present.



SKETCH PLAN OF THE SALFORD SEWAGE WORKS

We give above a sketch plan of the existing works, so that our readers may more readily follow Mr. Corbett's proposals. From this report we gather that it is proposed to alter the existing tanks by lowering the cross walls and practically to have only two long parallel tanks with dwarf cross walls. It appears, too, that the Council have already accepted the principle of filtration of the effluent from the precipitation tanks, and have at the present time contracts in hand for plant for loading the sludge steamer. The structural requirements for the complete treatment of the sewage are thus narrowed down to three items, viz.:—(1) The removal of sludge from the precipitation tanks without in any way interfering with the continuous use of the tanks. (2) The provision of "roughing filters" for straining out the particles of solid matter from the tank effluent. (3) The final filtration of the clarified effluent. The average daily flow is on the increase, so in all the following estimates a bulk of twelve millions of gallons per twenty-four hours is allowed for.

Sludge.—A scheme for the removal of the liquid sludge is already under consideration by the Council. This consists of a travelling scoop, carried by a pontoon fitted with traversing gear, and flexible pipes for conveying the sludge to the iron pipes and open channel leading to the new sludge tanks. The estimated cost of removing the "slurry" by the above apparatus is set down at 1s. 8d. per million gallons of crude sewage passing through the tanks; and it is claimed that there would be no necessity to check the continuous flow through the tanks.

Roughing filters.—Long-continued tests with filters working at the rate of 12,000 gallons per square yard per diem, and cleansed by upward washing and surface raking, have completely satisfied the surveyor. It has even been found practicable—he writes—to work 40,000 gallons per square yard per day through a 3ft. filter of sand, with only 2ft. head of water, but here it is admitted the efficiency was reduced. "In the scheme now submitted an area of about 2040 square yards of roughing filters is provided by forming six separate filters in two easterly tanks of the existing twelve precipitation tanks. The cleansing of these filters by upward flow and surface raking, and occasionally by a thorough turning over and washing of their sand, would only occupy a small portion of the time for each filter; but even allowing for one filter being out of use and only five at work, when dealing with 12 millions of gallons of sewage per day, the average flow would be only 7048 gallons per square yard per day, so these filters could readily treat an increased flow during rainy weather up to three or fourfold the ordinary flow." Provision is for the mechanical cleansing of the filters by sand-washing machinery travelling on rails laid on the side walls of the beds, and it is estimated that about £4820 will cover the cost of construction of filters, channels, valves, &c., including the sand-washing engine. The cost of working is put down at 2s. 11d. per million gallons of effluent passed through the filters. We are told that the action of these beds would be similar to that of the coke breeze filters at Glasgow Sewage Works, or the "clarifier" of the "International" process. They could quickly be constructed, and would remove all serious ground of complaint, pending the full completion of the works. The borough analyst—Mr. Carter Bell—reports that repeated samples of effluent from the experimental filter show an almost complete removal of all matters in suspension, and a slight reduction in the albumenoid ammonia.

Final filtration.—Mr. Corbett, writing at great length on this head, proves himself no friend to the modern patentee of filtering "media." Indeed, if his contention proves in the result to be well founded, it seems to strike a veritable death blow at all such materials as polarite, magnetic carbide, magnetite, and the like. Arguing from the experience of the several London Water Companies, the Wakefield Corporation, and the recent experiments at Laurence, Mass, U.S.A., the surveyor deducts that ordinary sand filters, "duly aërated by intervals of rest and drainage, will *permanently* purify sewage." (The italics are ours.) This *permanent* efficiency he indicates is due to the intermittent action of the filter "by inducing a growth of air-breathing bacteria which transform the offensive sewage effluent into harmless products. Careful experiments," he continues, "with special patented materials proved definitely that these high-priced filtering substances are no better than, if as good as, so much clean sharp sand. Somewhat similar experiments in the filtration of clarified sewage, carried on for about three years past by the London County Council with filters of burnt ballast, of sand, of coke breeze, and of sand with a layer of special material, proved that there was no decided difference between these filters, and that the one of coke breeze was slightly the best of the four. The mass of information obtained from these numerous investigations all indicates that the essentials of an efficient sewage filter are—(1) A hard, granular, durable material free from very fine particles, such as sharp sand with the finest grains riddled out, or coke breeze, or cinders, or crushed brick with the fine dust riddled out. (2) Arrangements for intermittent use, with thorough drainage and aëration in the intervals of rest, at least once a day, and preferably many times a day. (3) A flow of not more than 1000 gallons per square yard per day while in use, with 5ft. dep thof filtering materials. On these principles the Salford proposed aërated filters have been designed. The clarified effluent from the roughing filters would be carried by three separate main pipes to the aërated filters, each pipe having a controlling valve, so that one-third or two-thirds of the area can be shut off for aëration while the remaining part is in use, and thus each third of the area would be aërated once a day, or oftener. The filters are arranged in three sections, about 44 yards clear width, and averaging 164 yards in length, a total area of 20,640 square yards, providing for the filtration of twelve million gallons per day, at the rate of 582 gallons per yard of total filter area. The filters are spaced into breadths of eleven yards by lines of tram-rails and gangway planks, supported on cast iron pillars, which also form conduit pipes leading up to the distributing pipes presently described. The filtering material would be sand, coke breeze, cinders, brick dust, crushed stone, or any other hard, granular, durable material of 5ft. depth, but with height of walls, &c., ready for adding material to 8ft. depth if required. The clarified sewage would be distributed over the surface of the filters by a network of iron pipes with spray jets, and the filtered effluent would be collected into a 4ft. culvert, under a road alongside the southern boundary fence. This culvert would discharge into a small fishpond, where the pure quality of the effluent would be always visible, and from thence it would pass over a long weir on one side of the intercepting sewer outfall culvert, and so into the Ship Canal. A sand-washing engine, similar to that to be used on the roughing filters, would be in constant use on these aërated filters, washing and opening up the sand so as to continually renovate the filters by removing the insoluble particles and glutinous matter, which tend to choke any filter which is not periodically opened up and cleansed throughout. It is estimated that it will be necessary to wash the top layer of filtering sand every six months, the next layer every twelve months, and the bottom layer every two years, and the sand-washing engine proposed is quite capable of doing this work during ordinary working hours."

Cost.—The same report, dealing with the question of cost of the above scheme, sets down £19,390 to cover the construction of the 20,640 square yards of aërating filters, complete with all their pipes, valves, culverts, pond, &c. "The filtering material would cost about £6900, and the sand-washing engine £600, a total of £26,890. The annual cost of working and of interest, sinking fund, &c., would be about £2423, equal to 11s. 1d. per million gallons filtered."

Chemicals.—Mr. Corbett finds that there are "so many chemical systems, any of which might serve," that he does not attempt to select one at the moment. He, however, assures his committee that "it will be practicable when the roughing filters are at work to considerably reduce the quantity of chemicals used," because he is satisfied "that roughing filters alone, without any tanks or chemicals, can remove 50 or 60 per cent. of the impurities of sewage. It will also be practicable," the report states, "by substituting simple lifting and mixing machinery for the excessive amount of hand labour now employed to effect further economies, so that the total cost of chemicals, machinery, and labour for the precipitation process would not exceed 15s. per million gallons, say thus:—5 cwt. sulphate of iron at 1s., 10 cwt. lime at 8d., and 3s. 4d. by 12 equals 40s. per day for wages of ten men. The total annual expenditure on sewage treatment, apart from sewage pumping, and sewage disposal by steamer, is estimated at £6870, equal to 31s. 5d. per million gallons of sewage treated. "This," we are told in conclusion, "is the practical outcome of Salford's long-continued experiments."

We are free to admit that it may possibly be an economical policy to avoid "any handing over of the sewage works to patentees or speculators," but at the same time we shall await with keen interest the reception which the above scheme will meet at the hands of the Local Government Board.

Since the above was written a special meeting of the Salford Council has been held, at which Mr. Corbett's scheme and report were discussed at great length. In the end the following amendment was passed unanimously:—"That the scheme as submitted be adopted, with the exception of the provision of 12,360 square yards of aërating filters at a cost of £15,700, and that the height of the walls of the filter beds be reduced from 8ft., as proposed by the borough engineer, to 5ft. 6in., or 6in. above the level of the filter bed, and that the committee have discretionary power to increase the size of the aërating filters by 4000 square yards." In other words, it is decided to reduce the area of filters from 33,000 square yards, as contemplated by the committee, to the original 20,640 square yards referred to in the surveyor's report, with the discretionary addition of a possible 4000 square yards. This will reduce the total estimate from £50,718 to £35,018, to which must be added the extra cost of the 4000 square yards of filter if constructed; but against this possible cost must be set the saving effected by reducing the depth of all the walls from 8ft. to 5ft. 6in. throughout.

On Friday last this question came before his honour Judge Parry, sitting in the Manchester County Court, when counsel for the Corporation applied for a further extension of time. Mr. Rycroft, for the Corporation, explained that application was already being made to the Local Government Board for borrowing powers to the extent of £40,000; and in the end the Mersey and Irwell Joint Committee, while not entirely approving the scheme above detailed, agreed to an adjournment of the proceedings for three months. The hearing will therefore be resumed on April 20th, at the Salford County Court.

The Institution of Junior Engineers.—At a meeting of this Institution, held at the Westminster Palace Hotel, Victoria-street, London, on Friday evening, January 10th, Mr. H. J. Young in the chair a lecture on "Problems connected with the Theory, Working and Testing of Gas Engines and Hot-air Motors," was delivered by one of the honorary members, Professor T. Hudson Beare, B.Sc., M. Inst. C.E. There was a very large attendance. The lecturer began by giving a short account of the early forms of hot-air motors, describing the Cayley, Stirling, and Ericsson motors, as representatives of the three classes into which he divided these engines. He gave a *résumé* of the long discussions at the Institution of Civil Engineers on the value of the regenerator, which led to a paper by Sir Wm.—then Mr.—Siemens, entitled "The Conversion of Heat into Mechanical Effect;" this was the first time the then novel mechanical theory of heat had been brought before engineers. A short description of the early gas engines, Lenoir, Otto, and Langen, and other forms was then given. Dealing next with the possible cycles which can be adopted for hot-air motors, the lecturer gave first a brief summary of the general principles of all heat motors. For each type certain temperature limits had been chosen, and the maximum possible efficiencies and the actual possible efficiencies of each were worked out, and shown in a table exhibited to the meeting. The cards for each cycle had also been prepared, and diagrams illustrating an engine of each class, the table and diagrams showing very clearly the large amount of power absorbed by the pumps in most of the large engines, to which circumstance was due their low mechanical efficiency. It was also pointed out how poor the average effective mean pressure obtainable was. The actual efficiencies reached in practice were then given, and the reasons, both thermo-dynamical and practical, why these motors failed so to reach their possible efficiencies were discussed. Professor Beare then proceeded to consider the gas engine. After indicating the advantages of the de Roche cycle, he contrasted the small amount of work spent in the pumping stroke in the gas engine as compared with the large amount it became in hot air motors. The question of the value of a regenerator in a gas engine was investigated, and the points illustrated by two fully worked-out examples; it was shown that the possible efficiency could be increased by its use, but probably at the expense of making the engine bulkier for a given power by reducing its effective mean pressure during the working stroke. The testing of gas engines was lastly dealt with, all the observations needed being fully treated; the difficulties in carrying them out, and the best means for ensuring accuracy of results were mentioned. The lecturer explained how it was possible to work out a complete heat balance for any gas engine, without directly measuring either the quantity of air used or the temperature of the exhaust. It was necessary to assume the temperature of the charge just when compression was about to begin, and it was shown that this must be about that of the jacket water. This was the only assumption to be made. Some interesting observations on the lecture were at its conclusion made by Mr. Henry Davey, M. Inst. C.E., Mr. G. Burls, Mr. W. J. Tennant, and Mr. H. G. Christ; and a vote of thanks was passed to the lecturer.

THE ENGINEER IN NAVAL WARFARE.

WE publish here the third and concluding lecture delivered by Lieut. Edwards at the U.S. Naval War College. The *World* says:

"The first lecture dealt with the work of the engineers in preparing the vessels for an active campaign. The second lecture told of the actual combat as Lieut. Edwards knows it might have been. To-day Lieut. Edwards, supposing that the United States fleet has won a victory, tells how repairs must be made to render the warships efficient again, and makes a strong plea for simpler and uniform construction in our war vessels. There is a mine of suggestion to cool the blood of over-heated jingoes in his words":—

"*After the battle.*—'Rejoin my flagship in three weeks,' signalled Vice-Admiral Ito to the commander of the Matsu-Shima as she steamed for Japan after the battle of the Yalu. With moderate steaming this vessel ought to have reached a dockyard in two days. Allowing three days for docking—which is more than the average time taken in Japan when no repairs are made to the hull or propeller—and at least two weeks were given for repairs. The only impairment which seriously interfered with her efficiency as a fighting machine was the disabling of the controlling valve of her 65-ton gun. The other repairs were scattered, and admitted of a large force to work upon them. The Matsu-Shima will ever be regarded by the Japanese as the historic ship of the Yalu, and Admiral Ito had a special love for this vessel, for upon her decks he had won his great victory. It was upon the military mast of this vessel that the kite flew which brought so much happiness to the sailors of Dai Nipon's fleet, and which was regarded as the harbinger of success. There were other good reasons why the Admiral was anxious to have the vessel join him at a very early day, and in giving three weeks for repairs it is fair to presume that they could not have been done in less time. This will give some idea of the delay experienced in making repairs to a modern cruiser. The workmanship of the several parts is of the highest order, and unusual care is taken in assembling them together. To withstand the pressure and strain which the parts are subjected to the best of material must be used, and the design must have much to commend it. Too many people have written of the strategy and tactics of a fleet in the piping times of peace and fair-weather cruising. In one of the publications of the United States Naval Institute, Fleet Engineer George Quick, of the Royal Navy, writes of 'The Organisation of the Naval Engineer Forces.' He particularly dwells upon their duties 'in the hour of battle and the week afterwards.' This earnest and talented officer has contributed one of the best and most important monographs that has ever been issued by a service journal. And yet his article stands out almost alone in that periodical as the one contribution which has been unnoticed and not deemed worthy of discussion. His views are sound, even though his words fall upon unwelcome ears. Our great land will yet profit by his warning, for he tells us things we should all know. He writes with an earnest affection for our navy, although in a service which may one day meet us in battle. But he assails too strongly, although very kindly, the traditions of the past, and therefore his able article has been unnoticed.

Where disability threatens.—In speaking of the impairment aboard war vessels he says:—'Let me give one small example of those things which are occurring every day in all navies. On July 13th, 1891, during target practice on board H.M.S. Trafalgar, the locking bolt of the after turret was broken, and the turret was practically useless for three days, although the ship's artificers worked night and day at the repairs. Here we see one-half of the fighting power of a ship of 11,940 tons and 12,000-horse power disabled for three days by the breaking of a single bolt. But if the breaking of a single locking bolt disables the half of the fighting power of a 12,000-ton ironclad, and the repairs of that defect require the labour of the whole ship's artificers for three days and nights, what may we expect when a ship has been engaged for an hour with an enemy of equal fighting power? How many mechanics will be required to repair damages after one heavy shell has exploded inboard? This question is easy to ask, but not so easy to answer.' With such facts before us it must be recognised that the breakdown of the engineering department during action means the total loss of the ship or its usefulness for offensive work completely destroyed. If any part of a shackle is defective, the result may be as serious as the breaking of the strongest link in the chain. The failure of a piston-rod to have a well-rounded fillet on its shoulder may cause the same wrecking of cylinders that occurred on the Ericsson. The blowing out of a single tube may disable a boiler and interfere with the efficient working of others.

Reliable machinery.—The distinguished naval architect, Sir W. H. White, in a paper read before the Royal Society, expressed the opinion 'that modern ships will not stand more than one well-contested engagement, and many naval officers share this view.' Thus declared the *Army and Navy Gazette* less than a year ago and after the battle of the Yalu. To prepare for such a day, our vessels should be designed accordingly. There should be no stinting of weights in the engine-room. Rather than do this, decrease the width of the armour belt and cut down the bunker supply. A leaky boiler and a poor condenser on a cruiser will reduce the steaming radius more than the removal of a hundred tons of coal. The engineer-in-chief of the Navy, in his uncompromising struggle against the reduction of machinery weights, is fighting the battle of our commanding officers rather than that of the chief engineer.

Providing for repairs.—Naval experts have now commenced to realise the necessity of making provision for executing repairs more promptly. The equipment of floating workshops is an outcome of the repeated breakdowns on war vessels, due to crowded machinery with excessively light parts. That inexcusable fad to make lighter machinery than one's neighbour is now going out of fashion, although we can rejoice in the fact that the custom did not have a strong foothold in America. It is no longer good form to be an advocate of a half-dozen kinds of motors aboard a single ship, for immense repair bills and disabled machines are the sequence of having steam, anhydrous ammonia, compressed air, hydraulic accumulators, and dynamos aboard the same vessel. The full measure of the specialist has been taken, and most of his projected machines now do not get beyond the designing-room, for the tendency is to simplify the auxiliaries and give each one more room and increased weight for its installation. This makes the several parts more accessible for overhauling, and decreases their liability to become impaired. In designing machinery for war vessels facility for examination and repairs is going to be considered a greater factor than it has been heretofore. That vessel is no longer regarded as useful which is constantly under repairs. In order to prepare for battle and to quickly recover from its effects, war vessels must be constructed for continuous service and not for trial trips. In building the several types the machinery should be made sufficiently strong, and more room should be given for its installation, which space could be found by taking part of the quarters of the officers. If this were done the vessels would be more serviceable in action, and there would be fewer repairs to make after battle was over. In the upbuilding of a navy, therefore, types and classes of vessels should be constructed. There should not be an aggregation of individual ships which embody the ideas of earnest specialists, but which have no relation to a comprehensive plan, and which require months to repair when disabled. There are many strategic reasons why there should be such classes, but from an engineer's standpoint the following are sufficient:—'Defects of design in the machinery would sooner be discovered and overcome. With men thoroughly acquainted with the fitting of several ships, it would be possible to make several changes in the *personnel* by which the engineer's force could quickly be re-organised after battle. The best method of maintaining the efficiency of the department, making necessary repairs, and doing the general overhauling, could be developed. From several permanently disabled vessels all but one might be rendered serviceable after battle if the impairment was in the machinery. Fleet drills and manœuvres could be carried on with more efficiency. Reliable uniform speeds could be secured more easily and rapidly. And the Admiral in command could get better work from his fleet, for his strategy and tactics could more easily be carried out.' It is true that the individual commander, by his skill, courage, and strategy, may render great service to the State and bring glory and renown to his career. The destiny of nations, however, will be decided by battles between fleets, and not engagements between ships.

Where repairs should be made.—To return to the narrative. A few days before the enemy had been attacked, the question of where and how the repairs could be made had been carefully considered by the Engineer-in-Chief, the Admiral in command of the Defence Fleet, and the Secretary of the Navy. Should the vessels be sent to a Navy-yard? How should they be repaired? These important questions were carefully inquired into. Except the vessels which required docking, it was determined not to send them to a Navy-yard for the following reasons:—Time was of the utmost importance in getting the fleet ready for sea again, and the history of the Navy-yards in previous emergencies showed that work could not be expedited there. Industrial engineering methods are incompatible with official routine, and the vessel, once within the grasp of a military clerical system, had to submit to vexatious delays. Until the conflict was finished it would be impossible to tell how extensive the repairs might be, and it was almost a certainty that private firms would be called upon for assistance. These establishments could not work in co-operation with naval plants. Their methods were altogether different, and there could not be harmony and efficient commingling of their forces. This was unhesitatingly told the Secretary of the Navy. Another fact which influenced the decision was the time that it had taken the North Atlantic Fleet the previous year to overhaul at the Navy-yard and the fraction of that time which it had taken sister ships on other stations to do the same general work. The Engineer-in-Chief showed so conclusively that the repairs could be made more promptly in Narragansett Bay, that his recommendation was endorsed by the Admiral of the Fleet. Considerable preparation had therefore been made for the reception of the vessels, and a strong corps of naval engineers and scientific mechanical experts had organised the various auxiliary repair stations and machine shops into one great plant, where all worked harmoniously in common. Except the vessels which required repairs to their hulls and propellers, our victorious fleet steamed to Narragansett Bay, and the several ships immediately commenced making repairs. Nearly every town and city on Narragansett Bay is within two hours of Boston or Worcester by rail. Within three hours nearly every manufacturing city in the Blackstone and Connecticut Valleys can be reached. The forts at Newport would deny an enemy entrance to the bay, and innumerable small boats could communicate between the fleet and Providence with impunity. Within two weeks a solid built-up crank shaft could be constructed in Providence for a small cruiser. Time will not permit me to tell of the advantages this bay would have for repairing the machinery and fittings of a fleet.

Director-General of Repairs.—From the auxiliary naval repair stations, from the manufacturing cities and towns along the Blackstone and Connecticut rivers, and from New York and its environs thousands of the best mechanics were sent to the vessels. Engineer-in-Chief Melville, by order of the President, was made the Director-General of Repairs. This appointment was received with unusual favour by the country, for one of the enemy's greatest engineering authorities had declared that Engineer-in-Chief Melville was the ablest chief of any manufacturing or constructing bureau that America ever had in her naval department. Our people remembered that even as a boy he had been a leader, for before he was eighteen years of age he had designed and constructed a breech-loading gun, during the civil war he had rendered important service, for he had originated the idea of a protected deck; that he had been particularly commended for his skill, ability, and readiness of resource on board the ill-fated Jeanette; that he had shown himself great in the unparalleled search for De Leng in the Lena Delta; that he had been greater still in the rehabilitation of the navy as Chief of the Bureau of Steam Engineering and as Engineer-in-Chief of the Navy. And the nation believed that his highest greatness could be reached in having his energy and matchless engineering talents directed to the restoration of a crippled fleet and the captured cruisers and battleships.

How the repairs were made.—The repair ships Fulton and Corliss within a few hours reached the fleet. Additional telegraph and telephone lines had been established within a day, the military telegraph engineers having put lines in a manner that had astonished even the officials of the Western Union Telegraph Company. Directed by the genius of able electricians, who had volunteered their services, there had been established in an incredibly short space of time, as a gift from the great electrical combine, a great electric light plant, which permitted the prosecution of the work at night. From all along the coast the scouts and Sound steamers brought tools and supplies. Under the inspiration of several fleet engineers and such men as D. H. Thompson and Gardner Sims, of Providence; S. B. Whiting and Asa Mattice, of Boston; Francis A. Pratt, of Hartford; C. W. Moore and Horace Lee, of New York; D. H. Tompkins, of Charlotte, N.C.; John Fritz, of Bethlehem; Coleman Sellers and J. J. de Kinder, of Philadelphia; and George W. Dickie, of San Francisco, Engineer-in-Chief Melville soon brought order out of chaos. There was not a machine shop in New England whose proprietor was not willing to turn his establishment into a naval repair station. Providence and Pawtucket, with their thousands of skilled mechanics, did the bulk of the work. Every small order was duplicated at different shops, and this was found an excellent method of pushing work. Many of the torpedo boats were repaired at Bristol, the genius of a Herreshoff personally superintending the direction and scope of the work.

No naval constructor in the battle.—During the progress of the repairs it was greatly regretted that not a single naval constructor had been aboard any of our vessels participating in the battle. The executive officer who was in charge of the construction department had important duties to perform in assisting the captain to fight the ship. Many questions relating to the principles of naval architecture had therefore to remain unanswered at the time. The enemy, however, had naval constructors aboard several of their large ships, and they furnished valuable information to their naval authorities, which would have been of inestimable benefit to the Engineer-in-Chief, could it have been secured during the few days following the battle. The mistake in not sending the constructors to sea having been recognised, one was ordered to each of the large vessels. The same success which had attended the detaching of the ordnance and engineer designer to sea-going ships was afterwards found in the case of the constructors. Particular improvements were noticed in the ventilating arrangements, in the improved facilities for coaling ships, hoisting boats, cleaning bilges, rigging gangway ladders, and in the location of cargo ports. Not having seen anything of the fight, many questions relating to the repairs which should have come within the province of the constructor had to be solved by the naval engineer, whose experience in the battle made him competent to decide intelligently.

Special work of the engineers.—The great work of the chief engineer and the assistants of the several ships was to overlook the repairs and suggest remedies and improvements. Their services at such a time were too valuable to give their attention to any single impairment. The limited room for working and the many local difficulties to be overcome in making repairs and doing general overhauling astonished the mechanical engineers from shore. They realised then more fully than ever before the responsibility connected with the efficient maintenance of the motive department of a war vessel. Vice benches, drilling and punching machines, anvils, and forges made a sad plight of what had once been snowy decks. No injury was done to them, however, as they had been covered by light flooring. To see the work done on these decks with hand tools reminded many of the time when there were but few machine tools, and when it was said that such firms as Fletcher, Harrison, and Co. had built the machinery of the North River steamboats on the sidewalks of New York. Bed plates and valve seats were faced in those days by experts with hand chisels, and equally as good work was done on many of the ships of the fleet. Loyally and patiently the shore mechanics worked. Within the cramped quarters of the back connections the boilermakers fitted patches. For hours the machinists strained themselves in scraping the linings of valve chests. The fitters, at the peril of their lives, removed and replaced overhead piping. Conscientious men crawled under cylinders and boilers to clean bilges and keep the boiler shells in a state of efficiency.

Excellent work of the triple-screw ships.—For three days after the battle, and while the other vessels of the fleet were being repaired, the triple-screw ships Columbia and Minneapolis were cruising off the New England coast, capturing transports and scouts which had been sent from Halifax and which had no knowledge of the battle. Even with her disabled starboard crews, the Minneapolis did brilliant work. From the time a prize was sighted until its capture the Columbia had no difficulty in steaming 21·5 knots; the Minneapolis with her two engines maintained a speed of nearly nineteen knots. The remarks of Admiral Fournier before the French Special Parliamentary Commission of Inquiry, undoubtedly reflect the views of our people in regard to these triple-screw vessels. The Admiral is thus officially reported: 'Wisdom should order us to abandon as soon as possible the construction of these ruinous mastodon battleships. The type of war vessel most useful is that of the triple-screw vessel Dupuy de Lôme.' He also said: 'The naval battle of the Yalu proved the truth of the following conclusions:—(1) The capital advantage of speed. (2) The superiority of rapid-fire guns over heavy guns. (3) The uselessness of heavy armour. We should insist upon speed, which is the weapon *par excellence* of modern warships.'

French praise for the cruiser.—The most glowing, and at the same time the most interested, praise of the Columbia was published in *La Patrie*, of Paris, on July 12th, under the signature of its editor-in-chief, M. Lucien Millevoye. He said:—'The fêtes at Kiel will have, perhaps, as an unexpected consequence a renovation of the French Navy. Do you know what our sailors have admired especially in the German waters? It was not the pomp displayed by William II. to dazzle them; it was neither the golden eagle of the Imperial helmet nor the theatrical show of German power. What has struck France and all Europe with surprise mixed with fright, is the speed of one of the vessels of the American fleet. The cruiser Columbia has manœuvred before all the congregated squadrons with marvellous agility. This is, indeed, the great war instrument of the naval fights of the future. What a strength in the hands of the hardy captains of the sea! Maritime war will be greatly changed by it. That vessel, the Columbia, will be able to accept or refuse combat, according to its wishes. It will thunder forth shot and shell or run away at will. It can with impunity cover the surface of the ocean with ruins and wrecks, or laugh at the avengers sent to pursue it. The European nation, which would have the foresight to create a large number of those terrible cruisers would be unassailable, invulnerable, and invincible.'

An even keel.—One of the lessons impressively taught during the progress of the battle, and which caused certain work to be done during the course of the repairs, was this: That keeping ships on an even keel may have an important bearing upon the efficiency of a vessel in action. There are several causes which may list a ship quickly, and unless special provision is made to overcome such accidents, it may be a question of hours before the vessel can be put on an even keel. A list of 10 deg. would expose the plates below the armour, and in this way a battleship might be sunk by the rapid-fire gun of a torpedo chaser or a gunboat. Anything happening to either boilers or bunkers on one side might cause the list. There are several causes which might make it impossible to use coal equally from both sides of a vessel. Leaky tubes, the blowing out of a rivet, the breaking of some attachment to the shell, may all cause the water to run out of a boiler. The impact of the heaviest shell upon the side armour may start the joint and may rupture the steam and water piping; and boilers will undoubtedly be disabled in this way. Trimming tanks being a necessity, they were so placed that they were under the control of the chief engineer. They were connected to the main circulating and other pumps, so that they could be quickly emptied or filled. Every longitudinal bulkhead had some contrivance, whereby communication could be instantly established between the compartments which they separated.

Torpedo boats after battle.—An examination of the captured torpedo boats showed that the boilers and engines had been forced to their utmost. A few of the grate bars had been melted down and the tubes leaked considerably from the forcing which they had been subjected to. In the effort of the boats to escape, the working pressure had been exceeded and the blowers had been run at an excessive speed. Driving these small boats into a heavy sea had subjected the engines to shock. The anti-attrition metal had run out of one of the crank-pins and several bearings. Some of the discharge valves of the air pump had been carried away, which had greatly impaired the efficiency of the condensers. The condition of the engine and fire-room force was pitiable. For nearly a month these men had been under a great strain, both physical and mental. The long trip from Halifax had severely taxed them, and after reaching the Massachusetts coast their work was not lessened, for the boats were kept on the go constantly in doing messenger service. The character of the work performed in the engine and fire-room of such boats has been told by Mr. John I. Thornycroft, who is the peer of any builder in the world of any such craft. Personal and financial reasons would prompt him to declare that this work was within the ability of the average man, but Mr. Thornycroft speaks plainly to those purchasing boats from him.

Work on torpedo boats.—In a recently delivered lecture on torpedo boat destroyers, in which he referred to the excessive work performed in the engine-room, Mr. Thornycroft says—Lieut. Edwards quoted from THE ENGINEER:—Speaking of the firing, he said the stokers have to exert themselves much more than when firing the ordinary slow-working boiler, for when the boat is running at full speed, if the crew are divided in two watches, it would mean that each man must stoke about 600 indicated horse-power of boiler, which is many times the ordinary rate of working, and necessarily requires very good men. Again, as it is important to run the engines very fast, it may be interesting to consider how the artificers in charge of them are taxed by this necessity and compare the running of torpedo boat engines with the engines that were used in the first steam vessels, which made few revolutions in a minute, examples of which are still to be found in tug boats, for which they are suitable. If we turn from the comfortable-working heavy engine of the tug or river boats to the high-speed torpedo boat engine working at its highest power, we then note that the sound in the engine-room is confused by the addition of a number of auxiliary engines, each adding its own peculiar series of sounds to the noise of at least three cylinders of the main engine; and all these engines making a confusion which is further complicated by the fact that the auxiliary engines in their rate of working keep no constant ratio to each other or the main engines; they may be considered as part of an orchestra having a separate conductor for each instrument. Now take the next important sense for the engine-driver—feeling. The engines are revolving, say, 400 revolutions in a minute, and the important moving parts must be touched by the fingers and any change of temperature detected promptly. If this is not done, heating may ensue, which may oblige the engines to be stopped. In this rapid working the eye is even put to a great disadvantage. The motion is so rapid that no particular position of any working part can be assigned to it, while a spray of water and oil is thrown in the eyes and the vision temporarily impaired. However, this description only applies to running at the highest speed. At full power the firing scarcely ever ceases, and the forced draught gives such a high temperature in the furnaces as to render the light blinding and painful to the eyes, making the use of coloured glass necessary to protect the eyes when examining the furnace to see in what part the fuel is most required. The space for stoking is limited, and the coal bunkers, being small, cannot afford convenient room for the coal being rapidly trimmed from them. The very large amount of air passing through the stokehold causes coal dust to be carried about so as to be most unpleasant. In all this dust and hurry the water level and steam pressure must be attentively watched, and we owe much to our stokers for performing these duties, which are of the first importance for the speed and safety of the boat.

Changes made in torpedo boats.—In writing unofficially the naval engineer inspector of the Ericsson made some excellent suggestions in regard to the design and construction of torpedo boats and their machinery. In view of the fact that something sad is always happening to such boats of every nation, his views were carried out in repairing the boats which took part in the battle. His ideas upon the subject were as follows:—'In designing torpedo boat machinery, the great risk to men below should be uppermost in mind. The great watchword should be, the least possible number of pipes. It would be better to dispense with pipes that could only be used in a remote contingency. No piping should be installed which does not directly influence the speed. In short, one pipe for many services, not many pipes for one service. The pass-over steam pipe on the Ericsson had never been used during the twelve trial trips. On the steam pipes from the boilers, on the engine-room side of each fire-room bulkhead, there should be fitted a butterfly valve to be worked from deck; a man to be on watch with orders to throw down the lever on the instant of an explosion. No time was lost in shutting the Ericsson's valves, yet the time consumed in doing so was appreciable. The necessity of an open hatch over the whole length of the engine-room should be appreciated and provided for. The structural strength necessary should be given by cross beams; a cover, to be fitted when necessary, could always be carried and the hatch made strong enough to withstand the shock from any sea. The constructors would object, but the lives of men must be of more consideration than inexcusable precedent. A plate at the forward end of the engine-room was off; size, 2ft. 10in. by 4ft. 6in. The course of the steam was directly up and forward and much came through this opening. Had this plate been on, matters would have been worse. Had there been a complete open hatch matters would have been much better. The great danger from explosion, besides scalding, is the inhalation of steam. The old-time rule in case of an explosion is to get flat down and grope out. Hence air passages or holes should be provided for, by which, in case of an explosion, they could be immediately opened from deck and the whole volume of air from the fire-room blowers should be sent along the engine-room floor-plates. The broken pipe will always be high up, and the great volume of air suddenly thrown in at the bottom of the engine-room would unquestionably be of benefit to men fighting for their lives. This idea in connection with the open hatch must appeal to everybody. The form of ladders and their location in the boat should be a subject of great thought and care. They should be fitted in the most available space for reaching the deck.'

Work after battle.—In addition to the repairs on the machinery and boilers of the disabled vessels, there were other important things to be considered in getting the vessels ready for sea. The experience acquired during the conflict caused many changes to be made in the design of minor parts, and the working out of the details was no easy task. The new men had to be instructed in the performance of their duties. When it was remembered that the Texas has over seven hundred valves and twenty-five miles of piping, one can get a faint idea of the intelligence and ability of the machinists who are expected to successfully operate the many contrivances. Even before the fleet started for Narragansett Bay an additional force of firemen and machinists from the other vessels had been placed on board the Columbia and Minneapolis in order to help bring home the prizes which should fall within their grasp. It was night and day work with the engine-room force. Men who are working out important applications of mechanical principles cannot lay down their work and peacefully fall to sleep; but restlessly the brain continues to work out the solution even after the eyelids close.

Uselessness of repair vessels to a defence fleet.—This month's experience proved that repair ships for a fleet operating in home waters and in close proximity to the great manufacturing establishments were of little use. If they carried machinery they crowded out the men. The routine work of the ship had to be carried on, and she had to steam at a fair speed from place to place. There were numberless things which could be secured on shore to hasten repairs which could not be obtained on the repair ships. The number of fittings connected with a vessel like the New York, with her one hundred steam cylinders of various machines, runs up in the thousands, and at times it must be necessary to secure special parts from the manufacturers to make repairs. Skilled mechanics, who were experts in the management of machine tools, were useless in the fire-room, and in their ignorance of man-of-war rules they were constantly violating regulations. Vexatious delays occurred in securing and handling material and altogether the experience with the floating workshop was not a success. It was afterwards said that our enemy found them very useful in their fleet operations under conditions where time was not a factor in the matter. The repair ship was designed at a time when it was believed that vessels could be self-sustaining in regard to repairs. Time was not regarded as such a supreme factor as it is now known to be. They may be useful for a blockading fleet; as storeships they are valuable even to a defence fleet.

Reorganising the engineer's force.—One of the most important questions that arose after the battle was the reorganisation of the engine and fire-room watches. There is not a steamer afloat in which there is not some specially troublesome machine or valve, either in the engine or fire-room, and which requires special skill or knowledge on the part of some one to overcome its weakness. The failure of this auxiliary to work may have an important effect upon the efficiency of the main engines. There are some things which cannot be told; they must be acquired gradually by experience. If all our commanding officers realised how skilful, resourceful, and patient a good water tender should be, these men would receive more consideration than is now accorded them. If it should be our policy to use water-tube boilers, then the duties of the water tender will require an even more efficient man for this work than in the past. From the deck force men may be found to relieve the second-class firemen and coal passers; but the machinists, boiler-makers, coppersmiths, oilers, water tenders, and first-class firemen cannot be secured from the seaman contingent. That day has passed when the average oiler could relieve a machinist. On a modern war vessel a boilermaker might make a cruise without doing any work in the engine-room. So long as we act upon the defensive and are within a day's reach of New York, deficiencies in the engineer's force may be made up.

Insufficient engineer force.—The error of that policy which has permitted the best machinery in the world to be neglected by having an inadequate force of naval engineers was soon evident. The percentage of engineers who had become incapacitated, or had gone down in their ships, was greater than that in any other corps. The intense heat of the department, the strain of controlling and directing men who were worn out with toil, the shattering of their constitutions by the impact of shell upon the side armour, and the concentration of thought in overcoming impairments and casualties, had played havoc with the commissioned officers of the engineer's force. The few engineers that had been on duty on shore to supervise important work, were sent to the fleet as the reliefs of those who had been exhausted. Exceeding difficulty was found in making up the engineer's complement. It was only done after the passage of special laws, which permitted the engineer to give the full measure of his services to the Government. The number of engineer officers has been cut down very low in the British Navy, and still lower in the United States Navy. I say they have been cut down dangerously low, because in war time a very slight accident may disable the two or three engineer officers, and leave the engineer department entirely headless.

Vital necessity of repairing quickly.—It is impossible to overestimate the importance of the speedy repair of the machinery of ships of war after an action, for the gaining of only a few hours in effecting repairs after battle may decide most important naval operations following upon either a slight or severe engagement. It is not a good argument to say that our ships will carry as many artificers or mechanics as foreign ships, and that consequently there is no need to increase the staff of mechanics on board our ships. For if two similar ships engage, and each receives similar injuries so that they are compelled to cease fighting and withdraw for repairs, then if one of those ships carries, say, only thirty skilled mechanics for effecting repairs, while the other carries sixty mechanics, the latter ought surely to be in fighting condition first, and must assuredly capture or destroy the fomer. The sting of a defeat might be removed by a defence fleet which made speedy repairs, for with the aid of workmen from shore, the ships might be put in readiness so quickly that the blockading ships could again be attacked before repairs could be effected by the limited number of overworked machinists on board those vessels. The New England coast, although it would be a rich prize for a hostile fleet, has elements of strength in its manufacturing establishments which may play an important part in a naval conflict.

An engineer's warship.—And when the rewards were distributed to those who had rendered service to the fleet, a strong public sentiment demanded that the Director-General of Repairs and the Fleet Engineer be signally honoured. These men then said that as a grateful country had recognised their knowledge of the requirements of a modern war vessel and fleet, they be permitted to build what should be known to all the world as an engineer's ideal ship of war. It would be one that would do the work which was expected of her. Upon this subject the greatest engineering paper in the world has thus spoken: 'Miles of letterpress have been printed and published and read and discussed concerning the construction and qualities of ships of war. We cannot call to mind that any of these disquisiuions, or treatises, or papers, or books have emanated exclusively from the brains of engineers. Of course, without the aid of the engineer the modern warship could have no existence. But hitherto he has always taken a second place. He has been told to do this, that, and the other thing, and he has gone and done it; but little deference has been paid to any of his rare expressions of opinion. He has been told that naval matters are too hard for him, and that his true function consists in accomplishing the tasks set for him, and asking no questions. He is shown, for example, a very limited space on certain plans, and told to put engines and boilers into it which shall develope 10,000-horse power, or some other trifle of that nature; but he is not allowed to suggest that if he had a freer hand he could produce a better speed result, let us say, for less power. He is told that a gun is to be worked in a particular way, and that he must have the machinery for so working it; but he is not permitted to point out that the thing permits of being done in another way. He is not snubbed exactly, but he has been taught to keep his own place, and stand, hat in hand, when the naval architect, the artillerist, and the sailor pass by. Considering how very important is the part played in a compulsory, disjointed fashion by the engineer, we venture to think that he has not been treated quite in the way that he deserves, and we go so far as to ask, Is it not about time that the engineer took the initiative, and, reversing the normal practice employed the naval architect and the artillerist to carry out his designs? We hold that there can be but one sound answer to this question, and it may not be unprofitable to consider what way the engineer would probably go to work. It goes without saying that he would come to the task of designing a fighting ship with a very fair knowledge of what has already been done, and with a mind quite free from prejudice. His first endeavour would be to produce an honest ship, a vessel quite free from shams of all kinds. He will be moderate in his promises, but then they will certainly be kept. As to the shape of the hull, and the lines, these must be settled by the naval architect, acting under the general instructions of the engineer. It would be clearly understood that the speed settled upon would be the true sea speed of the ship, and not a fancy result got on a four hours' run with picked coal and selected stokers. There would always be precisely similar vessels cruising in company. They would be as much alike as three Martini-Henry rifles. Every part of each would be interchangeable with any other of the three, and as the sea speeds of all would be the same, there would be no waiting for the slowest, and they could always keep in company, save in the wildest weather. In one word, the engineer's warship would be less of a scientific museum and more of a floating gun-carriage. Her claims would be modest, but what she promised to do she could do. The story told by past naval manœuvres goes to show that the promises of the modern warship are seldom kept; and this simply because more is attempted than the wit of man can carry out.'

What it could do.—When the engineer's ship of war was finished, it was observed that she could be coaled quickly, and steered more readily and reliably. She could steam faster for a protracted period because sufficient weight had been allowed to instal reliable auxiliaries. Her bilges were accessible for cleaning. Considerable judgment had been exercised in providing for a system of ventilating the compartments. The fire main was a reliable one, and it was not impaired by numerous sharp angles and bends. The quarters of the officers were cut down, but the crew was more comfortable and contented. In case it was found necessary to abandon the ship, there were enough boats to carry the entire ship's company, and these boats were of such a character that they could live in a seaway. There was something else than an obsolete and ill-continued system of ladders and approaches to the hatches. A simple and efficient way of battening down had been fitted. The electric light plant was installed near the boilers, and where it could receive the care and supervision of capable mechanics. It was the production of a sea-going expert, not the creation of a theoretical scientist."

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

A DECIDED improvement has taken place in the trade of the port during the past week. A large number of vessels has arrived in both the Alexandra and Old Docks. In fact, both docks may be safely described as being crowded. In confirmation of this we may state that several steamers have been at the buoys waiting berths for a considerable number of hours. The price of steam coal has also advanced. Stems are well filled up all round, and there can be no doubt about it that shipping will be in a state of great activity for some time to come. A good demand for pitwood prevails at last week's prices. The ship-repairing trade has been brisk, all firms having been well employed.

Prices ruling on 'Change to-day was as follows:—Coal, best steam, 8s. 6d. to 9s.; seconds, 8s. to 8s. 3d.; best house coal, 10s. 6d.; dock screenings, 5s.; colliery, small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 6d. Pig iron: Scotch warrants, 46s. 1½d.; hematite warrants, 47s. 3d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 3d. prompt; Middlesbrough hematite, 45s. 3d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 10s. to £4 15s.; light ditto, £4 15s. to £5; tin-plate bars, £3 17s. 6d. to £4; Siemens tin-plate bars, best, £4, all delivered in the district cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 3d.; Siemens coke, finish, 9s. 6d.; ternes, per double box, 28 by 20c., 21s. to 22s. Pitwood, 16s. to 16s. 3d. London Exchange telegram: Copper, £41 5s.; Straits tin, £59 2s.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

AN improvement is noticeable in the iron trade this week on the tone manifested at the quarterly meetings, the result of the less threatening attitude of continental and South African diplomacy, and of the stronger character of the Cleveland and Barrow markets. Less indisposition is shown by consumers to operate, and the excessive caution of last week is subsiding. Marked bars keep at £7, merchant sorts £6 to £6 10s., and common £5 10s. Merchants quote a minimum of £10s. 7s. 6d. for galvanised corrugated sheets, but makers mostly require £10 10s. to £10 12s. 6d., and for best brands £11 10s., f.o.b. at outports. Mail advices from Australia bring news of a better demand for galvanised sheets at Sydney, and of an advance of 10s. per ton in some of the leading brands.

The remarkable manner in which the export demand for galvanised iron keeps up is matter of much gratifying comment. The completed shipments for last year have beaten all previous records, and surpassed even the greatest expectations of local makers, who were reckoning on a total shipment of 200,000 tons at most. Instead the figures come out 204,200 tons. For 1894 the total was 169,500 tons, and for 1893, 166,660 tons, so that last year has exceeded 1894 by 34,700 tons and 1893 by 37,600 tons. This is a marvellous performance for this class of iron. The largest customer on the year has been Australia, with 40,780 tons, an amount 500 tons in excess of two years ago, and only 1000 tons less than in 1894. India, which has been rapidly improving for twelve months past, takes second place with 38,800 tons, an advance on 1894 of no less than 11,000 tons and on 1893 of 10,300 tons. South Africa, which has advanced as remarkably as India, has been the third largest buyer, having purchased 33,500 tons, against 20,600 a year ago, and 20,300 tons two years ago, showing in each case an advance of 10,000 tons. The Argentine Republic is fourth with 19,600 tons, against 18,300 tons in 1894 and 16,000 tons in 1893, thus showing an increase of 1300 tons on a year and 3600 tons on two years ago. "Other countries" unenumerated appear for 20,600 tons, an increase of 2300 tons on 1894 and 4000 tons on 1893; and Chili has taken 10,800 tons, compared with 8500 tons in 1894 and 9700 tons in 1893. Never before have such returns been presented by the galvanised sheet iron trade, and their condition affords the liveliest prospects for the year that has now been entered upon.

In the pig iron trade stocks at the furnaces have accumulated somewhat during December and the holidays period; but makers are resisting the temptation to put all the iron on the market at once, believing that patience will be rewarded by better values. Derbyshire forge pigs are stronger this week and are quoted at 42s., and Northamptons 41s. to 41s. 6d. Foundry pigs are 45s. to 46s. for Derbyshires, and 44s. to 45s. for good Northamptons. Staffordshire cinder pigs are quoted 37s. for forge, and 38s. 9d. to £2 for common foundry iron. Staffordshire part-mines to compete with imported Midland pigs are quoted 42s. 6d. forge, and 47s. 6d. to 48s. for foundry, and occasionally on to 50s. nominal. Staffordshire mine iron—best forge—is quoted 44s., and foundry 55s. per ton.

The following figures show the number of furnaces built and in blast respectively at the opening of 1896:—Staffordshire South, 69 and 22; Staffordshire North, 38 and 14; Shropshire, 10 and 6; Nottinghamshire, 26 and 14; Lincolnshire, 21 and 14; Leicestershire, 4 and 3; Derbyshire, 52 and 30. The following are the increases in the number of furnaces in blast at the opening of 1896 compared with three months previously:—Staffordshire South, 1; Staffordshire North, 1; Derbyshire, 1; Leicestershire, none; Lincolnshire, none; Northamptonshire, none; Nottinghamshire, none; Shropshire, none. In the cases were no progress has been made, the number of furnaces now blowing is the same as a quarter ago.

Steel is still in large sale, and prices are maintained better than for iron. Bessemer basic angles of local manufacture are quoted £5 5s. for railway wagon building and engineering purposes; bridge plates and tees and channels, £5 10s.; boiler plates, £6; bars (flats), £5 10s.; and large shafting bars, £5 15s. to £6. Current prices are 5s. to 10s. per ton higher than this time last year.

Another meeting of the new combination in the Birmingham metal trade has been held, at which it was reported that there were now very few firms standing out from the movement, while more than two-thirds of the trade had given it their active support. Mr. E. J. Smith, of Birmingham, the well-known promoter of these new form trade combinations, was appointed chairman, and he was instructed to confer with the workmen on the subject of a proposed alliance between employers and employed.

Birmingham manufacturers view with much satisfaction this week the more pacifie aspect of Transvaal affairs. A large business is done between Birmingham and the Transvaal in engines, machinery, tubes, galvanised corrugated sheets, tools, and a great variety of miscellaneous metal goods. Several large Birmingham merchants have depôts of their own at Cape Town, Durban, Port Elizabeth, and other recognised trading centres. A few of the larger Birmingham manufacturing firms also are directly represented, not only in the South African ports, but in the Transvaal itself. Tangyes, Limited, for instance, have a large establishment in Johannesburg, and in pumping and mining plant and machinery they probably do the largest trade on the Rand. Another Birmingham manufacturing firm that is directly represented in Johannesburg is that of Lloyd and Lloyd, there being a great demand out there for iron and steel tubes of all descriptions. The stamping machinery, and other apparatus for dealing with the auriferous material when it is brought to the surface, is supplied, as far as this country is concerned, by London and other firms outside the Midlands, and is largely of American invention. The engines, however, and the engineering and winding appliances, are sent out, to a predominating extent, from Birmingham and the Black Country. One of the biggest orders now, and for some years back, in the trade with the Transvaal, and, indeed, with South Africa generally, has been in corrugated sheets and other galvanised goods. Dudley and the Walsall district, with Birmingham, share largely in the trade in gas and water pipes necessitated by the rapid commercial and municipal developments. For mining and cultivating tools of all kinds there has been a considerable demand from this district.

This week the Miners' Federation of Great Britain have been holding their annual conference in Birmingham. The proceedings opened on Tuesday with a luminous address by Mr. B. Pickard, M.P., President, dealing with the Employers' Liability and Eight Hours questions, internal competition among coalowners and low prices in the coal trade, a minimum wage for miners, and other subjects. On Wednesday a resolution was passed by the Conference declaring that no Employers' Liability Bill would be satisfactory which contains a contracting-out clause, and another resolution instructing the Executive of the Federation to press forward the Eight Hours Bill in the next session of Parliament. Other business was transacted on the remaining days of the sitting From the character of the President's address, and the general temper of the Conference, it seems entirely unlikely that the Federation will consent to any reduction of wages this year, but will stipulate for a continuance of the existing scale.

Mr. J. Robson, late manager of the steel mills at the Shelton Bar Iron and Steel Company's Works, Hanley, was on Saturday evening entertained to dinner, and presented with a gold watch, chain, and pendant, by a number of the mill employés, on the occasion of his leaving the company. Mr. W. Grey, in making the presentation, said that Mr. Robson had been their manager for about three years. They had learned to respect and esteem him, and had made that presentation because they had learned to regard him as a sincere friend. Mr. Robson, in replying, said that he should never forget the men who had worked under him at the Shelton Bar Mills. Mrs. Robson also was presented with a bread tray and knife with electro mounts.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—During the past week a decided change for the better has come over the iron trade here. The brightening foreign outlook, and the more hopeful prospects which are now entertained in well-informed quarters of some early settlement of the shipbuilding dispute, have both tended to dispel the depression which overclouded the opening of the year, and there is returning confidence in the market, the first evidence of which is the strong upward move in warrants during the past few days, and the lessened disposition to undersell on the part of speculative operators, whilst buyers who have been holding back in the expectation of lower prices, are now coming forward with their orders. The recent disturbance of the market, as I have previously reported, has been all along regarded as not more than temporary, and the quick recovery in prices only affords additional proof of the healthy condition of trade, and the general feeling of confidence as to the future. The opinion everywhere expressed has been that the upset of the market would soon pass over, and that with the large weight of work ahead already known as coming forward, the prospects of trade for the ensuing year were more satisfactory than they had been for a very long time past.

The Manchester Iron Exchange on Tuesday was well attended, and there was a better tone generally throughout the market, with more inquiries stirring. Although there is still not more than a moderate weight of actual business doing, buyers who have been holding back are showing more disposition to place orders at prices which a week or so back they were not willing to give, whilst some of the outside brands of pig iron could scarcely be brought within 6d. to 9d. per ton of the figures which sellers in some cases would have readily accepted quite recently. There is still a good deal of pressure on the part of users of pig iron to get down prices, but local and district makers who have not been in any way sensibly affected by the fluctuations in warrants, remain firm at their quoted list rates—the only exception being that Derbyshire foundry brands, which of late have been quoted at somewhat prohibitive prices, are not quite maintaining these, and are getting back to a more reasonable selling basis. For Lancashire foundry pig iron, makers still quote 46s., less 2½, whilst Lincolnshire makers remain in the position that they are mostly so heavily sold as to be indifferent about quoting at all, and their prices remain firm at 41s. 6d. for forge to 43s. 6d. for foundry, net cash, as the minimum for delivery equal to Manchester. Derbyshire foundry, which has lately been quoted as high as 48s., might, however, now be bought, according to brand, from about 45s. 6d. and 46s. up to 47s. net cash, delivered here. One or two fairly good orders have been put through in outside brands at improved prices, 45s. 4d. to 45s. 10d. net cash, being now the minimum for Middlesbrough, delivered Manchester, whilst in Scotch iron business has been done at 47s. 3d. to 47s. 6d. for Eglinton, and 48s. 3d. for Glengarnock, net prompt cash, delivered Lancashire ports.

A steady tone is generally reported in the finished iron trade, makers booking sufficient new business to keep them fully going, and they are firm at the recent quoted rates of £5 10s. for Lancashire, to £5 15s. for North Staffords ire bars; £7 10s. to £7 12s. 6d. for sheets; and £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths of hoops, delivered Manchester district, and 2s. 6d. less for shipment.

No very material improvement can be reported in the steel trade, ordinary foundry hematites being still obtainable at about 55s. 6d., less 2½, delivered Manchester, and steel boiler plates at from £6 to £6 5s. per ton, but rather better prices have been got for steel bars.

The position throughout the engineering industries continues generally satisfactory, most branches being fairly well supplied with work, whilst in some departments the leading firms have orders on their books which will keep them fully engaged for well over the remainder of the year, this applying especially to stationary engine builders, one or two of the locomotive builders, and machinists, whilst boiler-makers are also better off for orders than they have been recently, and machine tool makers generally are all well engaged and report new work coming forward satisfactorily.

The employment returns of the trades union societies are also a further satisfactory indication of the improved condition of trade. The continued dispute in the shipbuilding industry necessarily keeps up the general percentage of out-of-work members at a comparatively high figure, the Amalgamated Society of Engineers having about 8 per cent. of the total membership in receipt of out-of-work support; but, notwithstanding this, the returns compare favourably with those for the same period of last year. In this immediate district there is a continued steady decrease in the unemployed list, which now represents about 4 per cent. of the local membership in receipt of out-of-work benefit; and this probably may be taken to represent something like what the position would be throughout the society, but for the large number on the books, in connection with the disputes at Belfast and on the Clyde. The reports received from the various branches in this immediate district also show a decided revival in some branches which have been but moderately employed, and perhaps the most conclusive evidence of this increasing activity is a pressing demand for pattern-makers and smiths, which, I understand, the local secretary of the Amalgamated Society of Engineers now finds some difficulty in meeting.

Mr. Joseph Nasmith, the new President of the Manchester Association of Engineers, delivered his inaugural address to the members of the Society at their meeting on Saturday. It was, he said, not an easy task to select a subject for an address of that kind, but it was following a good precedent to deal with that side of engineering with which the president for the time being was most familiar, and he had taken as his subject the inventive epoch in the cotton trade, which would perhaps possess some features of novelty to many members. The president then, after an interesting historical survey of the growth of the textile art, the origin of which was, he said, completely lost in antiquity, dealt at length with the development of modern inventive skill as applied to the cotton manufacturing industry, accompanying his remarks with numerous illustrations of machinery and appliances, as typical of the progressive stages in attaining the present, if not absolutely perfect, still remarkably high position of efficiency. In conclusion, he said it was impossible to close without a word on a side of the question which was of deep interest. One of the first results of the invention of the various machines to which he had referred was the destruction of the old system of working, and the substitution of a new one. The household industries had been gradually proving inadequate for the needs of the nation, and when the adoption of the fly-shuttle led to an enormous increase in the demand for yarn, it could only be met with the new frames. The development of the steam engine released manufacturers from the necessity of depending upon water power, and speedily led to an increase in the size of the machines, until in 1812 mules of 700 to 800 spindles were in extensive use. To employ these it was necessary to collect under one roof the whole of the machinery necessary for preparation, and the independent spinner and weaver became transformed into the factory hand, and the system of organised industry arose. From this system had arisen by slow degrees that extension of popular liberties which had rendered this country the finest, and on the whole the most prosperous which the world had ever seen. The efforts of our machinists and engineers had also been directed to the improvement of the instruments of production, and these had in turn led to enormous improvements in the structures used to contain the machines, until working conditions were approaching the ideal. There was further a marked improvement within the last generation in the physique of cotton operatives, as it was proved beyond doubt that the industrial victory rested with the population which was best fed and best paid. On the motion of Mr. Ashbury, seconded by Mr. T. Daniels, a vote of thanks was unanimously passed to the president for his valuable address, and Mr. Nasmith in responding, incidentally observed that notwithstanding what the Americans might say as to the mule being a "doomed instrument," there was no sign of any extensive change from it as yet.

There is still no improvement in the coal trade; although in most cases pits continue working about five days per week, supplies, now that the extra pressure following immediately on the resumption of work after the holidays has disappeared, are excessive, and prices, if anything, easier. The better qualities of round coal suitable for house fire purposes move off slowly for the season of the year, with no quotable change in list rates, which, however, are barely being maintained. Common round coals continue in but very indifferent request, with excessively low prices ruling, 6s. to 6s. 6d. being the full average prices for good ordinary qualities at the pit mouth. Engine fuel meets with a moderate demand, but supplies are ample, and prices are not more than steady at late quotations, common slack being readily obtainable at 3s. to 3s. 6d., and better qualities 4s. 6d. to 5s. per ton at the pit mouth.

Only a very limited weight of business comes forward in the shipping trade, with very low prices accepted to get hold of business, ordinary steam coal not fetching more than 7s., except in very special cases; whilst as low as 4s. 6d. per ton has been taken on sales of good rough slack, delivered Mersey ports.

Barrow.—There is a much healthier feeling in the hematite trade this week, and not only has the sale increased locally, but there is evidence of further improvement all round. Prices accordingly are stiffening. Warrant holders ask 47s., net cash, and buyers 1s. less. Makers quote 48s. to 49s. per ton, net, f.o.b., for mixed Bessemer numbers.

Stocks of hematite iron have been reduced during the week to the extent of 560 tons. They now represnt 297,876 tons, being an increase of 8701 tons since the 22nd of December last. There are thirty-five furnaces in blast, compared with thirty in the corresponding week of last year.

Iron ore is only a poor trade, as although the consumption is heavier, foreign cargoes are being brought in. Average native qualities are at 10s. per ton, net, at mines.

The steel trade is busier than it has been for some time. Indeed, all departments are now at work at Barrow. The plate mills, which have been idle for six months, are again in full swing, and orders are fairly well held, and the demand is good and likely to be better. The rail mills are still busy, and orders are reported good, while prices are up at £4 15s. per ton for heavy sections, net, f.o.b. Billets, hoops, and castings are all good trades, and the year's prospects are all round brighter.

In the shipbuilding trade there is plenty of activity, and the work in hand is being pushed forward very satisfactorily. New orders are expected.

In the coal and coke trades there is more firmness, and a better demand is springing up on manufacturing account.

Shipments have been rather fuller this week. The exports of pig iron from West Coast ports during last week were 6865 tous, and of steel 4621 tons, as compared with 2248 tons of pig iron and 6931 tons of steel, an increase of 4617 tons of pig iron and a decrease of 2310 tons of steel. The total shipments since Dec. 21st last have been 13,996 tons of pig iron and 23,148 tons of steel, as compared with 5213 tons of pig iron and 15,604 tons of steel in the corresponding period of last year, an increase of 8783 tons of pig iron and of 7544 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE pits are now fairly well employed, and a better business is looked for in the near future. The production has been about an average one during the past week, the present unseasonable weather greatly affecting the demand for household qualities of fuel. The London and southern markets have taken only a moderate amount, while a similar remark applies to the eastern and other markets. No improvement will be reported in this business until a spell of cold weather comes. Competition is very keen, and the small tonnage in demand gives seaborne coal a considerable advantage. Quotations are said to be higher, although in many cases buyers can obtain concessions. Silkstone coal is at 9s. to 9s. 6d. for the best, and 7s. 6d. to 8s. for the secondary sorts. Flockton coal, which is only produced in about five local pits, is sold at 8s. 3d. to 8s. 6d., with best classes of thin seam at 6s. 3d. to 6s. 6d. Barnsley house coal of good quality can be disposed of at 8s. to 8s. 6d. per ton. Notwithstanding the lateness of the season, there is a good tonnage of coal being sent to the Humber ports. Stocks are accumulating, however, owing to owners having to raise both seams of coal at the same time. The business done with Hull is about the same as is usual during the first month of the year. Prices are as follows:—Barnsley hards, 6s. 6d. to 7s. 3d. for the best, and 6s. to 6s. 3d. for secondary qualities, a quotation which is a little lower than when last reported. Gas coal continues in good request, while 6s. 6d. to 7s. is all that can be obtained for supplies. Local pits are doing an active trade with Yorkshire manufacturing districts in engine fuel and slack. Nuts make from 5s. 6d. to 6s., and Barnsley pit slack 3s. to 3s. 9d., with screened ordinary pit slack at 2s. 3d. to 2s. 6d. per ton. Smudge is again plentiful at cheap rates. The coke trade is rather more active. North Lincolnshire is doing a larger business, and an increase in the number of blast furnaces, which is expected soon, will materially add to the consumption. Derbyshire, on the other hand, is transacting but a poor trade, smelters not ordering so freely as usual.

The trouble in the Transvaal has not had such an adverse effect on the Sheffield heavy industries as was anticipated when war broke out. Firms engaged in the production of miners' shovels, picks, machine stamps, crucible steel for drills, and similar goods, report a large number of orders, which have been received from their London agents and direct from South Africa. None of these have been cancelled by telegram, but this dispute will lessen the number of requirements following those at present on their way to this country. Railway material manufacturers report an excellent business doing in tires, axles, springs, buffers, and other locomotive parts. In view of these facts it is expected that these departments will be well employed for some months to come. Quotations remain about the same as when last reported. Bessemer billets are at from £5 12s. 6d. to £6, with bar iron at £5 10s. at makers' works. Hematites are quoted at 57s. 6d. to 60s. Marine material is in poor request, owing mainly to the strikes on the Clyde and at Belfast, which are unfortunately still continuing. These decreased requirements are also due to the small number of new ships now being ordered, in consequence of the lowness of freights, there being hardly sufficient employment for the ships at present floating. Messrs. Charles Cammell and Co., Messrs. John Brown and Co., and Messrs. Vickers, Sons, and Co. are well employed on armour plates for the British Admiralty, and it is anticipated that the latest political trouble will bring about an entirely new naval programme.

In the lighter trades the New Year appears to be opening very well. Sheffield is undoubtedly making satisfactory progress in electro-plate and silver manufactures, in spite not only of home opposition, but of the keen competition of Germany. Troubles in South Africa, it is expected, will tell against the demand which has so readily risen in that region for the best classes of silver goods. So far, however, we do not hear that any of the indents have been countermanded, but there is little doubt that the next mail from the South African markets will be a small one, and manufacturers at present have not been pushing forward shipments until affairs have settled down. South Africa is taking a large value of goods in machine stamps, crucible cast steel for drills, disintegrators, and all the varied appliances required in the mining industry, while mining shovels, of a special pattern, are also freely ordered. At home there is a capital demand for contractors' tools, spades, shovels, hammers, axes, and similar goods, in which manufacturers have been well employed all the year, and 1896 promises to be quite as fertile in work. Houses which produce hand-cut files, as well as those which adopt file-cutting machines, are very busy. Best cutlery has been in good demand, a noteworthy tendency of trade having been the call for articles displaying artistic taste at a moderate price. Several of our manufacturers are at length taking a leaf out of the foreigner's book and offering attractive productions at low figures. It is high time this step was taken, as the tendency towards cheaper goods becomes more and more manifest every day.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

A VERY decided change for the better has set in this week in nearly all departments of the iron and steel industries, and the tone now is as hopeful as it was despondent last week, while confidence is rapidly returning, and a disposition to buy is becoming very manifest. The reason for the improvement is that the fears that were entertained about the grave political complications have subsided, and it is now generally the opinion that trade will not be hampered by the hostilities that were threatened, but that "peace and plenty" will be the lot of commercial men this year. The unsatisfactory state of political matters has undoubtedly been the main cause of the last 2s. fall in pig iron prices, and now that they are more reassuring, considerable recovery is looked for, even during the winter months, though these are the quietest in the year.

Distinct evidences of revival are everywhere apparent, and must be more so after the termination of the Clyde-Belfast engineering dispute, which has done so much to interfere with trade in this district and Scotland during the last two months or more. The belief that the difficulty would come to an end very shortly has had something to do with the improvement in the market this week, as has also the excellent Board of Trade returns and the good accounts of traffic receipts issued by the railway companies. The feeling generally is now inclined to be optimistic, and thus is the opposite of what it was last week.

Pig iron makers have done a fairly satisfactory business this week, and generally have realised higher prices. No. 3 Cleveland pig iron — the standard quality — has risen 9d. — and thus is back to the figure that ruled a month ago. Consumers, influenced by the general improvement, are becoming anxious to buy for forward delivery, but they find it difficult to induce either makers or merchants to sell for other than prompt delivery at present. Last week No. 3 could have been bought at 36s. 3d. per ton; this week there are plenty of consumers willing to purchase at 36s. 9d., but they now have to pay at least 37s., and most of the producers have put up their quotation to 37s. 3d. Cleveland warrants on Tuesday went up to 37s. 1d., cash, which was 11½d. advance on the previous Tuesday's rate, but on Wednesday 37s. 5½d. was the rate.

It is satisfactory to see that the stock of Cleveland pig iron in the public warrant stores is not increasing so rapidly as it did in December, owing doubtless to better shipments. The stock held by Messrs. Connal and Co. on Wednesday night was 176,063 tons, or 4363 tons increase this month. The pig iron exports from the Cleveland district this month have been 32,296 tons, as compared with 24,616 tons last month, and 18,664 tons in the corresponding month of last year to the 15th. No. 1 Cleveland pig iron is at 38s. 3d.; No. 4 foundry at 36s. 6d.; grey forge at 35s. 9d.; and white at 35s.

The market for East Coast hematite pig iron is dull and weak, notwithstanding the activity in the steel trade, and the price has not moved up in sympathy with that of Cleveland iron. Probably the low price of Middlesbrough hematite warrants induces people to hold off, but there is good reason to believe that the prices quoted on the warrant market for these warrants are fictitious, for brokers find it impossible to execute orders at any such prices, and directly an offer to buy is sent in, the price is run up at once. The quotation for mixed numbers of East Coast hematite pig iron is 45s. 6d., which is not an advance on last week. Rubio ore is firm at 12s. 6d. per ton delivered Tees, though rates of freight have dropped. Cleveland No. 3 basic pig iron is steady at 39s. 6d., but there is not much on sale.

The realised price of No. 3 Cleveland pig iron during the past quarter has, by the official accountants, been certified to be 36s. 5·06d., as compared with 35s. 1·51d., increase 1s. 3·55d., but the wages of the blast furnacemen are to be reduced this quarter by 2 per cent. The reason for this is that in October the men were given a special advance of 3¾ per cent., but the return just received proves that the condition of prices did not justify the payment of so much, and accordingly the wages have been reduced to the rates that the sliding scale gives. The cost of the carriage of iron-making materials will, however, be raised 10 per cent., as the railway rates for these are regulated by sliding scale based upon the realised price for No. 3 Cleveland pig iron. The average realised price for the year 1895 was 35s. 2·94d.

An extraordinary instance of the success of Belgian competition in this district is reported. Sir B. Samuelson and Co., at the Newport Ironworks, Middlesbrough, are adopting what is in this country a new plan for the manufacture of coke for their blast furnaces. Instead of having the coal converted into coke at the colliery, they are to have the raw coal carried to the ironworks and there converted. This plan is said to have been tried in Germany, and answers admirably, as a drier, harder, and better coke can be put into the furnace, and it has not to be handled so often. At Newport Ironworks, therefore, a large number of coke ovens are being erected for the firm by Mr. H. Simon, of Manchester, the patentee of the Simon-Carves, ovens, and, requiring a number of girders in the work, Mr. Simon has bought them in Belgium, though close to the Newport Works, and within half a mile of where the girders are used are the well-known mills of Messrs. Dorman, Long, and Co., who make the manufacture of builders' girders one of their specialities. This is competing with our own manufacturers even at their very doors.

The steel rail trade is very active; local works are fully employed with the exception of the Darlington, which are closed, and the large number of inquiries that are received justify the expectation that the activity will be continued. Orders on Indian account are numerous. Quotations for 17,000 tons for one of the Indian lines are asked; also for 17,000 tons for Mexico. A large quantity of steel sleepers have been recently sent to Mexico from the Tees. Railmakers maintain their quotation of £4 15s. net at works for heavy steel rails. Chair founders are doing better, but the improvement with them has not been anything like so pronounced as it is with the rail manufacturers, and instead of prices being put up 25s., as in the case of rails, the chair makers have to be content with 2s. 6d. advance, and find it difficult to get even that. The great activity in the rail trade has led to the circulation of various rumours about the re-opening of the Darlington Steel and Ironworks and their acquirement by other owners; but there appears to be no foundation for these reports.

The steel plate trade is improving as far as regards demand, but some makers have this week accepted reduced prices, for ship plates could be got at £4 17s. 6d., less 2½ per cent., at works, and there was a little businee done at £4 16s. 3d. Steel ship angles are now offered at £4 15s., less 2½ per cent., and iron angles at £4 12s. 6d., also less 2½ per cent. Some of the producers of common iron bars have been more successful in booking orders than they were in the last quarter, and generally the manufacturers speak more hopefully. The price of common bars is £4 17s. 6d., less 2½ per cent., at works, but orders might be placed at less.

The engineers find work more plentiful, and they expect a good year, but as yet they have been able to do little in the way of raising prices. This is especially the case with marine engineers. Locomotive engineers report more work, both on home account and for export. Wagon builders are also reporting more favourably of their position and prospects. The directors of the North-Eastern Railway are about to increase their wagon building operations at Shildon to more than double the present output. Inquiries for pipes are numerous, but competition is still too keen to permit of any substantial advance in the prices.

The coal trade is showing no improvement, and especially is the steam coal branch depressed. So unsatisfactory have been the prices during the last quarter that at a meeting of the Conciliation Board held at Newcastle, the umpire decided the wages were to be reduced 1½ per cent. for the present quarter. Best Northumberland steam coal can now be got at 7s. 9d. per ton f.o.b. The Durham coal trade is not quite so slack, but still is poor on the whole, partly because of the mildness of the weather. At Dunston-on-Tyne a few years ago the North-Eastern Railway Company constructed coal shipping staiths for the accommodation of the collieries in the north-west of Durham, and such has been the support accorded to them that the present accommodation is inadequate, and a deputation of the Coal Trade Association and other bodies concerned proposes to wait upon the railway directors to get them to enlarge the shipping facilities there. Last year's coal and coke exports from Tyne Dock amounted to 5,429,586 tons, as compared with 5,569,513 tons—a larger quantity, it is claimed, than has been shipped from any other dock in existence. Coke for blast furnace purposes is firm at 13s. per ton delivered at urnaces on Teesside or 14s. 6d. f.o.b.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a better feeling in the iron market this week. A large quantity of Scotch warrants changed hands at improving rates, the price advancing about 1s. per ton above the rates current last week. For Cleveland pig iron warrants there was but a poor demand in this market, but the prices rose in sympathy with Scotch iron. A moderate business took place in Cumberland hematite warrants, which also improved in price.

At Gartsherrie Ironworks there are 7 furnaces making hematite and 4 ordinary; Coltness, 8 and 1 respectively; Summerlee, 6 on ordinary; Calder, 4 on hematite and 1 ordinary; Shotts, 1 hematite and 3 ordinary; Carnbroe, 4 ordinary; Govan, 1 hematite and 5 ordinary; Clyde, 4 ordinary; Wishaw, 3 hematite and 1 ordinary; Glengarnock, 2 hematite, 4 basic, and 3 ordinary; Dalmellington, 1 hematite and 4 ordinary; Eglinton, 2 ordinary; Muirkirk, 3 ordinary; Lugar, 3 hematite and 2 ordinary; Carron, 2 ordinary. There are thus at the beginning of the year 30 furnaces making hematite, 4 basic, and 45 ordinary pig iron, the total number in blast being 79, and there are altogether 29 out of blast.

Although constant additions have been made to stocks in the last few months, they amount to not very much over one-third of the quantity in store half-a-dozen years ago. With moderate wages and cheap fuel, the ironmasters appear quite justified in turning out iron at the present rate of production.

There is a hardening tendency in the prices of the special brands of makers' iron which are improving a little in sympathy with warrants. When warrants receded badly, however, makers' iron ore fell away to a small extent, so that it may be expected warrants will recover further before there be much addition to the prices of the special brands. Govan and Monkland, Nos. 1, are quoted f.o.b. at Glasgow, 46s. 6d.; No. 3, 45s.; Coltness, Nor 1, 53s.; No. 3, 48s. 6d.; Summerlee, Calder, and Gartsherrie, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Clyde, No. 1, 50s.; No. 3, 47s.; Carnbroe, No. 1, 47s.; No. 3, 45s. 6d; M. and C., No. 3, 43s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s.; No. 3, 46s.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington, at Ayr, No. 1, 47s.; No. 3, 45s.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 48s.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 48s. 6d.

The pig iron shipments in the past week were small, being 5395 tons, against 3704 in the corresponding week of 1895. There was dispatched to India, 112 tons; Italy, 150; United States, 10; South America, 25; Australia, 10; France. 15; Germany, 30; Holland, 30; Belgium, 40; Spain and Portugal, 30; China and Japan, 500; other countries, 52; the coastwise shipments being 4391, compared with 2902 in the corresponding week.

The market for finished iron is quiet. Business has scarcely yet had time to assume normal proportions since the holidays. In the steel trade there is a fair promise of good employment if only labour disputes could be warded off, and that which now exists in the shipbuilding industry brought to a satisfactory conclusion. Prices of manufactured iron and steel have not changed materially since last week.

Several fresh shipbuilding contracts have been booked by Clyde builders in the last few days.

The coal trade is in a rather languid state, the past week's coal shipments from Scotch ports amounted to 92,953 tons, compared with 95,940 tons in the preceding week, and 101,197 tons in the corresponding week of last year. There has been a heavy falling off in the East Coast shipments, those from the Clyde showing a considerable increase. All classes of coal are at present slow of sale on Glasgow Exchange. The prices at the ship's side in Glasgow Harbour are for main coal 5s. 10d., splint 6s, 6d., ell 6s. 9d., and steam 7s. 6d. per ton.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE coal trade may fairly be described as satisfactory, and yet there are several districts that are in anything but a prosperous condition. The Plymouth colliers continue irresolute, and though meetings amongst them are frequent, it is quite possible that the end of the month will see a complete stoppage. In the Aberdare and Hirwain districts one firm employing 1100 men suspended operations lately. Ycyborwen Colliery, one of the oldest in the valley, is also closed, though it is stated that sixty acres remain unworked; this will put aside a number of men. The new drift at Dythus is being worked vigorously in that neighbourhood, and this will absorb some men- These partial upsets must be expected in an increased ratio as time goes on, old properties failing to pay, especially when in rivalry with new collieries, which can be more cheaply worked.

The total exports from Cardiff last week were satisfactory, 285,000 tons. Newport report was 40,064 tons foreign, and 20,515 coastwise. Swansea total was below the average, only 27,833 tons. At Cardiff a brisk business was reported this week, and the maintenance of good prices. On Saturday 10s. 6d. was firmly quoted for best steam coal. Early in the week the gratifying news was discussed on 'Change, Cardiff, that an extension of Government coal contracts in Wales was certain, to the substantial figure of 100,000 tons, so as to provide for all contingencies. Coal prospects are, then, tolerably good for some time to come. Most of the Welsh industries have suffered from the strained character of our foreign relations, but coal generally thrives in a war atmosphere. Cardiff prices mid-week were as follows:—Best steam coal, 10s. 6d.; seconds, 9s. 6d. to 10s.; drys, 9s. 6d. to 9s. 9d.; best Monmouthshire, 8s. 6d. to 8s. 9d.; seconds, 8s. to 8s. 3d.; best small, 5s. to 5s. 3d.; seconds, 4s. 3d. to 4s. 6d.; drys, 3s. 9d. to 4s.

The mildness of the weather of late has evidently told a little upon the house coal trade. As a rule, in the early part of the year, there is a greater amount of buoyancy about house coal than steam, but this year it is *vice versâ*, and for the last few days a degree of flatness has characterised most house qualities. Prices are much about the same, best being quoted at 10s. 6d. to 11s.; seconds, 10s.; No. 3, Rhondda, 9s. 9d. to 10s.; brush, 8s.; small, 6s. 3d. to 6s. 6d.; No. 2, Rhondda, 7s. 9d. to 8s.; through, 6s. 3d. to 6s. 6d.; small, 4s. 3d. to 4s. 6d. Swansea prices are: Best steam, 9s. 6d. to 10s. 6d.; second quality, 8s. 6d. to 9s. 3d.; small, 4s. 3d. to 4s. 9d.; No. 3, Rhondda, 10s. to 10s. 6d.; No. 2, Rhondda, 8s. 9d. to 9s. 6d.; Anthracite, from 8s. 9d. to 12s.

The patent fuel trade is moderately good at the various ports, Cardiff, Swansea, and Newport. Prices remain ranging from 10s. to 10s. 6d. Coke prices are unaltered. Pitwood at Cardiff this week realised from 16s. to 16s. 3d.; Swansea, 17s. 9d. to 18s. into truck. Iron ore at the same place is being quoted at 11s. 7½d. to 12s. A novel mixed cargo figured amongst the imports to Cardiff for Dowlais this week—"iron ore and salt," from Bilbao. Substantial consignments continue to arrive this open weather. One from Castro, for Ebbw Vale, 1680 tons, 1530 tons from Bilbao for La Société Commerciale, and several large cargoes for the Dowlais Iron Company.

There is not much of an encouraging nature to report in connection with the iron and steel trade. The condition of the tin-plate trade has told seriously upon the tin bar trade, and prospects ahead in that branch are rather gloomy, though not quite so bad as some have stated. Swansea Exchange reports this week indicated a fair degree of trade in steel rails, but a small one in steel bars. Quotations are as follows:—Steel rails, heavy, £4 10s. to £4 15s.; light, £4 15s. to £5 10s.; Welsh bars, £5 5s. to £5 7s. 6d.; steel and iron sheets, £6 5s. to £6 10s., with the usual extras for higher gauges. Bessemer steel, tin-plate bars, £3 17s. 6d. to £4; Siemens not quoted. Cardiff quotations are, Bessemer, £3 17s. 6d. to £4; and Siemens, £4 to £4 2s. 6d.

Swansea imports continue to be suggestive. Last week they included 862 tons pig iron; scrap iron, 150 tons; tin-plate bars, 400 tons; steel rails, 347 tons. Tin-plate exports were depressing to a degree. The quantity shipped was only 20,647 boxes, while 37,637 boxes came up for the works. In reviewing the December trade, the falling off in exports of tin-plates is very striking. To the United States the quantity sent in December, 1894, was 15,910 tons, and to Russia 3163 tons. December, 1895, the figures respectively were 10,635 tons and 2687 tons. The collective totals to Germany, France, Italy, Portugal, and Austria, shows also a serious decline.

I regret to announce the death of Captain Pomeroy, chief docks harbour master at Cardiff. He has been felicitously described as Sir. W. T. Lewis' right-hand man, and there is no doubt he was one of the ablest of his agents, not only in conducting the duties of his post, but in the getting up of dock extension plans and changes. He was an excellent witness on Parliamentary Committees. He was only in his fifty-second year. Speculation is rife as to the appointment of his successor. The vacancy is expected to be filled from without. Sir W. T. Lewis, Bart., is still absent in South Afrfca, and nothing will be done until his return.

Llanelly shipping indicates an increase. During December the exports amounted to 12,848 tons, as compared with 12,420 tons in November; this was exclusive of tin-plates. Imports 6566 tons, an increase of 655 tons over non-imports.

I have now the official totals of coal, and iron, and steel shipments from the leading Welsh ports for 1895; Cardiff during the year despatched 12,793,381 tons of coal, 43,824 tons of iron and steel, 81,941 tons of coke, and 388,995 tons of patent fuel. Newport, Mon., 3,412,854 tons coal, 18,140 tons iron and steel, 4717 tons of coke, and 55,531 tons patent fuel. Swansea, 1,794,481 coal, 1954 iron, 10,576 coke, and 297,320 patent fuel. Llanelly, 250,011 coal, 12 iron. As anticipated in my previous notice, there is a decrease in coal shipments. The total from Welsh ports in 1894 was 18,567,017 tons. The total in 1895 was 18,150,727 tons.

I am glad to hear that the well-known Abertillery seam of coal has been struck. It is understood that the London and South Wales Railway Bill has been withdrawn, certain concessions having been given by the Great Western Railway in the form of reduced fares, and railway improvements. The engineer's estimates respecting the Rhymney Bill in carrying out the construction of lines, &c., if sanctioned, is £97,597. Those of the South Wales and Bristol Direct Railway totals are £1,116,348. This scheme for shortening the route from Wales to London is estimated by local authorities to amount to £31,500 per mile.

With reference to the condition of the tin-plate trade, it was announced mid-week by Mr. W. Mann, of Morriston, that there was no immediate prospect of a restart at the Worcester Works, but if orders could be obtained, four mills might be set going at Upper Forest Works, the work at which might be shared by the employed.

At Gwendraeth, Kidwelly, it has been intimated that, owing to depressed state of the tin-plate trade, the works could not be kept going, unless the men conceded 15 per cent. and seven sheets per box, which would be equivalent to 25 per cent. reduction. So far the men appear resolute not to give way. In most quarters the outlook is bad. Thus, at the Villiers, Briton Ferry, only three mills worked last week. This meant half-time for the men. Mills at Earlswood were restarted Wednesday week. Vernon mills were all at work, but a notice is posted that will expire in three weeks. Last week three mills were at work at Raglan Bay, and three at the Gwalia. At Briton Ferry and at the Albion there was an average make of steel bars and a good demand.

At the last Birmingham quarterly meeting there was no improvement recorded in the tin-plate trade, but prices were advanced from the old selling prices of 9s. and 9s. 1½d. per box to 10s. and 11s. per box.

The South Wales Works, Llanelly, which employ 1000 hands, are in steady operation.

The extension of the Prince of Wales Dock, Swansea, has been decided upon—£100,000 to be borrowed. This and the threefold scheme—electric light, tramways, &c.—now before the Corporation, indicate that the port is going to open the year with vigour.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THIS week again only a moderate business has been transacted on the iron market, for, apart from the quietness that is always noticeable immediately after the holidays, there has been a slightly weakening tone perceptible in some branches, and the tendency of prices is not so firm as could be desired.

With regard to the iron trade in Silesia, a fair employment is on the whole maintained at the blast furnace works, and in the malleable iron department there has also been pretty much life stirring. Some of the larger ironworks, Borsig, for instance, Huldschinsky and Fulva Works, contemplate the extension of their establishments in spring. Tenders for the supply of a further large quantity of structural iron have lately been invited by the Breslau Railway Administration, and the orders will probably be secured by Breslau dealers. Compared to this time last year, prices for bars and structural iron are on an average M. 1·90 per 100 kgr. higher.

In Austria-Hungary the year has begun with a slight improvement in the quotations for some articles, the Convention of the Bohemian and Moravian rolling mills having resolved to raise bars and sectional iron 25 to 50 cr. per 100 kgr. This upward movement, which is due to the continuing favourable condition of the German iron market, will most likely lead to a general rise in quotations before long On the whole, there is very little doing in the pig iron trade, and few orders are holding out, but for manufactured iron a lively demand is experienced, and the steel trade is in healthy occupation, owing to the numerous contracts that have of late been placed by the Railway Administrations. The locomotive and wagon shops are reported to be in exceptionally good employment, the Kaiser-Ferdinand North Railway having ordered 100 passenger and freight cars, while two other railway companies have invited tenders for the supply of several hundred coal wagons and 2000 passenger and freight cars. The following figures, which have recently been published, show that consumption of coal in Hungary, which was extremely limited till 1867, has since then considerably increased. From 1867 to 1876 consumption was, in 100 kgr., 15 millions per annum; in 1880 it amounted to 20 millions; and in 1883 it rose to 27 millions. Since 1890 consumption of coal in Hungary was as under:—

	Pit coal.	Brown coal 100 kgr.	Totals.
1890	16,076,807	22,701,539	38,778,346
1891	18,318,050	24,504,790	42,822,840
1892	18,616,708	25,734,992	44,351,700
1893	20,018,767	29,409,818	49,428,585
1894	20,357,926	34,763,837	55,121,763

Compared to this, consumption in Austria was—for 1886, in 100 kgr., 160 millions; 1887, 175; 1888, 184; 1889, 190; 1890, 205 millions. And

	Pit coal.	Brown coal. 100 kgr.	Totals.
1893	119,060,223	100,497,977	219,558,200
1894	125,878,041	105,379,232	231,257,273

During the period from 1867 to 1876 the average output of coal in Hungary was, in 100 kgr., 13 millions; for 1877 production was 16 millions; 1878, 18; 1879, 16; 1884, 25; 1885, 25; 1886, 24; 1887, 25 millions. Import in coal also shows a considerable increase, having been, for 1883, in 100 kgr., 4 millions, which is exactly double the quantity that was imported in 1873. Since 1890 Hungarian business in coal was as follows:—

	Pit coal.	Brown coal. 100 kgr.	Totals.
1890.			
Production ..	9,948,117	22,504,462	32,452,579
Import	6,170,425	982,638	7,153,063
	16,118,542	23,487,100	39,605,642
Export	41,755	785,561	827,316
	16,976,787	22,701,539	38,778,326
1891.			
Production ..	10,193,522	24,279,263	34,472,785
Import	8,161,764	1,084,694	9,246,458
	18,355,286	25,363,957	43,719,243
Export . ..	37,236	859,167	869,403
	18,318,050	24,504,790	42,822,840
1892.			
Production ..	10,522,136	25,543,646	36,065,782

	18,675,214	26,541,909	45,217,123
Export	58,506	806,917	865,423
	18,616,708	25,734,992	44,351,700
1893.			
Production ..	9,827,982	29,178,991	39,006,973
Import	10,287,312	1,006,850	11,294,162
	20,115,294	30,185,841	50,301,135
Export	96,527	776,023	872,550
	20,018,767	29,409,818	49,428,585
1894.			
Production ..	10,000,000	34,000,000	44,000,000
Import	10,431,099	1,599,510	12,030,609
	20,431,099	35,599,510	56,030,609
Export	73,173	835,673	908,846
	20,357,926	34,763,837	55,721,763

The trade done on the French iron and steel market is, on the whole, but limited. Here and there rather more business is reported to be stirring in the manufactured iron department, but generally there is not much animation noticeable. Prices, though not showing the slightest inclination to rise, are tolerably firm.

The same may be told with regard to the Belgian iron industry, which has been dull during this week and the last, the mills and foundries being, on the whole, irregularly occupied, while the prices for most articles continue quite as low as ever.

Since beginning of December last year no change, either in prices or demand, can be noticed in the pig iron trade; for most sorts a good demand continues to be reported, and quotations exhibit considerable firmness. Spiegeleisen, 10 to 12 p.c. grade is quoted M. 53 p.t.; forge pig, No. 1, M. 48 to 49 p.t.; No. 3, M. 42 p.t.; hematite, M. 65 p.t.; foundry pig No. 1, M. 65 p.t.; No. 3, M. 56 p.t.; basic, M. 50 p.t.; Luxemburg forge pig, M. 45 p.t.

On the malleable iron market the tendency is firm, and even rising. Bars for home consumption are in fair request, considering the time of the year, and even from abroad rather more inquiries have been coming in lately. With regard to girders, only small purchases are being made just at present. At a recent meeting of the Rhenish-Westphalian rolling-mills, a rise of M. 2 p.t. for bars and girders has been resolved upon.

The position of the plate business is not very satisfactory. It is true there has been an increase in demand since October last year, but only the most favourably situated establishments can work with a profit, while the majority of the mills justly complain of the low, unremunerative prices they are still compelled to accept. In sheets demand has improved rather than otherwise. The wire and rivet business is quiet, but steady. At the machine and wagon factories a fair activity is going on, but the foundries are, on the whole, weakly engaged, and seem to be anxious to secure more contracts. At a late tendering for fish-plates, M. 120 p.t. was the lowest offer, others ranging between M. 121 and M. 142·40 p.t.

The following are the latest list quotations, per ton at works:—Good merchant bars, M. 108 to 110; angles, M. 118; girders, M. 84; hoops, M. 112 to 117; billets in basic and Bessemer, M. 80 to 83; heavy plates, for boiler-making purposes, M. 160; tank ditto, M. 135 to 140; steel plates, M. 125; tank ditto, M. 110 to 113; sheets, M. 135 to 145; iron wire rods, common quality, M. 118 and higher; drawn wire in iron or steel, M. 120 to 138; wire nails, M. 127 to 130; rivet iron, M. 130; rivets, M. 150 to 155; complete sets of wheels and axles, M. 270 to 280; axles, M. 200; steel tires, M. 195 to 200; steel rails, M. 108 to 110; steel sleepers, M. 106; fish-plates, M. 112 to 120; light section rails, M. 95.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, January 8th.

THE anticipated replenishment of the Federal Treasury, through in part popular subscriptions, has already exercised a favourable influence on business. The prompt action of the House in passing a measure to increase Government income is helpful in another direction. The enormous gold production and the encouraging possibilities of the Western gold field, are producing a good effect. The increasing evidences of an overwhelming Republican sentiment throughout the country is having a good effect in industrial directions. There has been a slight decline in iron and steel production. Prices have receded a little more. Large buyers are awaiting developments. Lake ores are out of reach, and coke must come down. The Pittsburgh iron region is overcrowded with work excepting in steel billets, and large buyers refuse to pay current rates. Sheet and plate mills are quite busy. All the cast iron pipe mills are full of orders. Rail orders come in slowly. Last year was the worst railroad year we ever had. There is much projected railroad building in the States and Mexico, and only favourable conditions are needed to stimulate construction. The standing drawback is that all our international obligations are payable in gold, and our creditors know we will never have gold enough to pay the principal. There is an encouraging increase in industrial activity throughout the Southern States.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

1st January, 1896.

1. Hydraulic Hoisting Apparatus, F. Eastmead, London.
2. Revolving Pumping Apparatus, F. W. Brewster, London.
3. Keel for Pleasure Sailing Vessels, T. O. Smith, Oxford.
4. "Drip" for Railway Carriages, &c., D. Tilsley, Limerick.
5. Treating Linseed Oil, J. E. and C. S. Bedford, Leeds.
6. Partitioned Box or Crate for Bottles, J. Brooks, Sheffield.
7. Oil Lamps, E. F. Hulse, Manchester.
8. Metallic Packing for Pistons, &c., W. Harbinger, South Shields.
9. Making Ammonium Compound of Casein, W. Majert, Manchester.
10. Shuttle Smash Preventer, P. J., A., and E. B. Evans and J. H. Clissold, Stroud.
11. Pneumatic-tired Wheels for Vehicles, J. Ralph, Wolverhampton.
12. Medicated Fruit Syrup, J. H. Dalwood and Co., Sherborne.
13. Stopping Leaks, J. C. Sellars, Liverpool.
14. Gas or Oil Motors, H. S. Booth, Manchester.
15. Mechanism for Branding Articles, R. Gibson, Dundee.
16. Moulding Pipes, H., J., and A. Coulthurst, Manchester.
17. Cycles, J. Robson, Birmingham.
18. Beetling Machinery, J. Downham, Manchester.
19. Patent Wood Block Flooring, J. W. Musselwhite, Basingstoke.
20. Gutta-percha Balls, R. Ramsbottom and H. J. Rofe, Manchester.
21. Making Vanillin, W. Majert, Manchester.
22. Driving Gear for Cycles, T. Lambert, Plymouth.
23. Safety Bolt Fastener, M. Rohleder, Cologne.
24. Ventilating and Air-moistening Apparatus, C. Buchmuller, Cologne.
25. Tear-off Calendar, E. H. Janssen, Cologne.
26. Cruet, Camera, Flower, &c., Stands, H. Moreton, Birmingham.
27. Construction of Casement Windows, C. Ower, Dundee.
28. Combined Window Sill and Flower Box, J. Paton, Glasgow.

301. Registering Device for Billiards, S. Lloyd, London.
302. Controlling Apparatus, E. C. Haines and F. B. Mills, London.
303. Smelting Ores, C. C. Longridge and G. T. Holloway, London.
304. Billiard Cues, C. H. M. Lyte, London.
305. Driving Chains for Bicycles, F. Ellis, London.
306. Electrical Apparatus for Cooking, J. Chambers, London.
307. Range-finder, G. Legh, London.
308. Electric Switches, C. S. Newman, London.
309. Brakes, K. Storey, London.
310. Scaffolding, F. G. Knopfe and H. A. Roder, London.
311. Driving Gear, F. P. Gautier, London.
312. Game, O. Sterkel, London.
313. Petroleum Motors, F. P. Gautier, London.

6th January, 1896.

314. Writing-desks, W. T. J. Parkes, London.
315. Soft Soldering Aluminium, W. H. Bennett, London.
316. Securing Card Clothing on the Flats of Carding Engines, G. P. Appleyard, Halifax.
317. Apparatus Applicable to Coke Ovens, G. Love, Durham.
318. Cylinder for Kilning Malt, W. Adlam and A. Wilson, Bristol.
319. Handles for Cycles, &c., S. Muir, Birmingham.
320. Plug for Closing Shot Holes, E. T. Whitelow, Manchester.
321. Bodkin, J. T. Williams, Swansea.
322. Purifying Acetylene Gas, J. C. Bayley, Bournemouth.
323. Portable Work Benches, E. Arnold, Bournemouth.
324. Window Fasteners, T. Franke, Manchester.
325. Tobacco Pipes, J. Jackson and A. White, Coventry.
326. Measuring Instrument for Tailors, D. Ritchie, Glasgow.
327. Attachment for Sewing-machines, W. H. Inslee, Glasgow.
328. Self-adjusting Horseshoe Rougher, E. W. Walker, Rugby.
329. Combination Hospital Locker, R. Cross, Blackburn.
330. Construction of Stretching Machines S Walker, Radcliffe.
331. Ships, I. Spy, Liverpool.
332. Car Coupling, J. Wagner and F. Jordan, Germany.
333. Clarifying Vegetable Juices, E. and C. Muller, Berlin.
334. Removal of Keyboard of Pianos, R. Mitchell-Bent, London.
335. Manufacture of Caustic Soda, H. R. Angel, London.
336. Toy Puzzle, W. J. Case, London.
337. Boilers for Hot-water Supply, R. P. Fisher, Sheffield.
338. Stoppers, J. Creasy, London.
339. Attachment to Perambulators, R. B. Fuller, London.
340. Cloths, G. Smith, London.
341. Engraving Machines, A. A, and L. Crossland and Co., Manchester.
342. Portable Electric Light, J. R. Welland, London.
343. Wheel Skates for Road Travelling, P. E. Masey, London.
344. Cigarette-paper Case, W. Bowden.—(*W. Bowden, Jamaica.*)
345. Inkstands and Inkwells, C. A. Maynard, London.
346. Boots, F. M. Boschet, London,
347. Switch for Electrical Purposes, C. B. Wood, London.
348. Holder for Use in Sharpening Tools, E. E. Harington, London.
349. Receptacle for Use of Sick Persons, H. J. Hyde, London.
350. Brakes for Cycles, &c., J. McVitty, London.
351. Building Construction, D. Johnston, London.
352. Photographic Printing, E. D. Percival, London.
353. Preventing Pipes Bursting, J. G. Jones, London.
354. Shower-bath Apparatus, &c., C. Carazetti, London.
355. Electric Regulator for Arc Lamps, A. L. Davis, London.
356. Drying of Goods, G. Seagrave and S. B. Bevington, London.
357. Dress Figures for Garments, O. Selleck, London.
358. Rotary Planing Machines, W. W. Hulse, London.
359. Phantoscopes, T. Armat, London.
360. Mechanism for Transmitting Motion, J. Paquet, London.
361. Separating Compounds from Gas, H. Bower, London.
362. Sheet Metal Pulleys, O. W. Ketchum, London.
363. Time Checking Apparatus, A. J. Boult.—(*V Chiron, France.*)
364. Hinges, C. Adamy and R. Tausk, London.
365. Guiding Devices for Lamps, A. J. Boult.—(*G. Wouters, Belgium.*)
366. Electrical Attachment to Valves, J. C. Berry, London.
367. Baby Carriages and like Vehicles, H. Noelte, London.
368. Organ Pipes, G. W. Scribner, and W. and J. A. McIntosh, London.
369. Cycles, A. Bugnon, London.
370. Cycles, H. C. Field and A W. Storey, London.
371. Photographic Developers, A. M. Clark.—(*Lembach and Schleicher, Germany.*)
372. Dyeing, A. M. Clark.—(*C. H. Boehringer Sohn, Germany.*)
373. Apparatus for Ventilating, &c., J. Cinnamon London.

374. Screw Socket Box Fixing Axle, W. S. Roberts, London.
375. Carts, R., J., and H. Wildor, London.
376. Bonnet Pins, Hair Pins, &c., H. F. L. Aumont, London.
377. Star Maps, G. Castleden, London.
378. Rulers, C. F. England, London.
379. Chain Driven Cycles, J. B. Paton, London.
380. Furnace Grates for Marine Boilers, C. Ware, London.
381. Harvesting Machines, J. Macphail, Chicago. U.S.A.
382. Manufacture of Cycles, &c., W. F. Taylor, Croydon.
383. Cycles, H. R. Yeo, Plymouth.

7th January, 1896.

384. Reducing Condensed Steam, &c., F. Levett, London.
385. Cure of Smoky Chimneys, E. H. R. D'Eye, Woodbridge.
386. Tennis Racquets, Racquet Bats, &c., H. C. Crawford, London.
387. Water-closets, T. Holt, jun., and S. Holt, Liverpool.
388. Semi-rotary Pump, W. Wheeler, Langley Green.
389. Gas Cooking Stoves, H. J. Yates, Birmingham.
390. Electrical Switches, J. T. Leroux, Birmingham.
391. Adjustable Wheels, W. T. Faizey, Astley Abbots.
392. Driving Bands, F. Smith and J. Ratcliffe, Keighley.
393. Axles, S. G. Whitehouse, London.
394. Oil Lamps, J. Simpson and J. MacGregor, Newcastle-on-Tyne.
395. Manufacture of Acetylene Gas, A. Garton, Huddersfield.
396. Armour for Warships, Forts, &c., T. Andrews, Manchester.
397. Construction of Razor Strops, W. Harrison, Sheffield.
398. Inhalers, T. B. and H. Wilcox, Manchester.
399. Glass Oil Vessels, J. Grime and P. Isherwood, Darwen.
400. Steam Generators, J. J. Tinker, Manchester.
401. Semi-metallic Packing, J. Kirkman, Chorley, Lancs.
402. Cycle Tires, J. Jack, Glasgow.
403. A Safety Clothes Pocket, J. Symington, Glasgow.
404. Type Writer, R. J. W. Down, Bristol.
405. Sluice Valves, J. Barr, Glasgow.
406. Wheel for Carriages, W. Campbell, Newcastle-on-Tyne.
407. Fixing and Adjusting Scythes, H. Newton, near Frome.
408. Stang Planimeter, E. Scott, Wolverhampton.
409. Device for Attaching Labels, &c., A. Barr, Glasgow.
410. Grippers for Printing Presses, J. Watson, Glasgow.
411. Tires for Road Vehicle Wheels, J. Pinch, London.
412. Sewing Machines, W. H. Inslee.—(*The Singer Manufacturing Company, United States.*)
413. Tables, W. H. Inslee.—(*The Singer Manufacturing Company, United States.*)
414. Screw Stocks and Dies, S. Saunders, Manchester.
415. Portable Balances, F. P. Bolshaw, Liverpool.
416. Cigar Cases, G. Nathan and R. Hayes, Birmingham.
417. Underclothing, W. H. Cunningham and W. M. Middlemass, Edinburgh.
418. Fish Plates for Railways, J. Quertier, Bournemouth.
419. Clips for Cuff Holders, C. F. Mackness, Forfarshire.
420. Dental Hand Pieces, J. T. Pedersen, London.
421. Apparatus for Sharpening Band Knives, W. Beecroft, London.
422. Lasting Boots and Shoes, A. E. Stickler, London.
423. Apparatus for Driving Tacks, A. E. Strickler, London.
424. Cooling and Heating Air, G. E. Sherwin, Birmingham.
425. Smoke Cleansing Apparatus, J. Nemecek and F. W. Keitsch, London.
426. Type Writer, G. Royle, London.
427. Cycles, J. G. Hudson, London
428. Breech-loading Fire-arms, J. W. A. Rule, London.
429. Method of Constructing Metal Boxes, H. Piquet, London.
430. Window Sash Locks, P. S. Riddelle, London.
431. Revolvinq Window Sashes, P. S. Riddelle, London.
432. Pistols for Shooting Marbles, W. E. Everitt, London.
433. Locks, R. Muller and A. Muller, London.
434. Phase Completing Device, T. McKenna.—(*Electric Selector and Signal Company, United States.*)
435. Timing Horses, H. A. Lugrin and M. D. Fielding, London.
436. Sealing Jars, H. Birkbeck.—(*J. Boyle, United States.*)
437. Stopping Runaway Horses, W. Crawford, London.
438. A Safety Valve for Boilers, T. Potterton, London.
439. Shirts, F. W. Hamlin, London.
440. Construction of Bedsteads, A. Wainwright, London.
441. Reels of Cotton, C. Syrett and J. W. Rowe, London.
442. Umbrellas, L. Grouard and O. Levilly, London.
443. Polishing Material, O. Imray.—(*M. M. Kann, United States.*)
444. Boots and Shoes, K. F. Jekeli, London.
445. Pneumatic Knife-cleaning Machine, F. Bramley, London.
446. Controlling Gas Supply, H. L. Leslie, Birmingham.
447. Trawling, W. Jackson, London.
448. Air Pumps, C. E. Hearson, London.
449. Compass for Heavy Rain Signal, A. M. Gallett, London.
450. Photography, G. J. Bull and B. F. C. Costelloe, London.
451. Wood-cutting Machines, H. H. Lake.—(*W. F. Hutchinson and E. Gould, United States.*)
452. Electric Motors, H. H. Lake.—(*B. A. Fiske, United States.*)
453. Bush Hammers, G. Main, London.
454. Receipt Blanks, H. H. Lake.—(*D. P. Fackler, United States.*)
455. Spinning Machines, J. A. Miller, London.
456. Musical Instruments, H. H. Lake.—(*The Aeolian Company, United States.*)
457. Harvesting Machines, J. F. Appleby, London.
458. Tables for Bookbinding Machines, H. H. Lake. —(*A. G. Mackay, United States.*)
459. Light Ports for Marine Vessels, W. K. Mackenzie and C. Chamberlain, London.
460. Elastic Tires for Velocipedes, N. Wahl, London.
461. Toys, W. A. Hunter, Liverpool.
462. Dramatic Appliances or Clothing, W. G. Hurst, Liverpool.
463. Extensible or Leaf Tables, W. Edwards, Liverpool.
464. Wrapper Case for Music, E. E. Smith, Liverpool.
465. Machine for Sweeping Streets, D. E. Hipwell, London.
466. Perforators, H. P. Lavender, London.
467. Ships and other Vessels, W. L. Phillips and A. Gluck, London.
468. Drop Keels for Sailing Vessels, C. G. Dixon-Johnson, London.
69. Separating Substances of Different Sizes, J. U. Askham, London.
470. Fire-grates, J. D. Hannah, London.
471. Coin-freed Apparatus, E. Hollanders, C. J. Leather, and T. Taylor, London.
472. Manufacture of Transfer Sheets, G. Grossheim, London.
473. Friction Clutch for Vehicles, W. C. Bersey, London.
474. Turning Plate for Vehicles, W. C. Bersey, London.
475. Electric Accumulators, W. C. Bersey, London.
476. Combination Tools, O. E. Morse and E. H. Brundage, London.
477. Electrical Storage Accumulators, C. N. Stewart, London.
478. Rotary Engines, O. E. Morse, London.
479. Burner or Wick Cap for Liquid Fuel, C. Bourbott, London.
480. Street-car Brakes, R. Haddan.—(*L. S. Fish, United States.*)
481. Diving Bell for Great Depths, J. P. Rossander, London.
482. Bottling Liquids, F. M. Lyte and C. H. M. Lyte, London.
483. Socket for Wire Rope Ends, W. H. Becker, London.
484. Rein Grips, E. Wright, London.
485. Fastening Doors, Windows, &c., G. Inman, London.
486. Washing Machines, H. J. Heinze, London.
487. Cycle Wheels E. J. Spence, London.

8th January, 1896.

488. Ventilating Workshops, &c., F. Pilkington, London.
489. Sinker for Use in Fishing, S. Allcock, Redditch.
490. Protectors for Horseshoes, R. Abell, Derby.
491. Candlesticks, H. H. Kirby and W. B. Ward, Birmingham.
492. Finishing Woollen Fabrics, J. and G. A. Baxter, and W. H. Hare, Bradford.
493. Cycle Driving Gear, R. Stark, Glasgow.
494. A Mechanical Cue, T. W. Vipond, Newcastle-on-Tyne.
495. Self-registering Lineal Measure, B. Vallance, London.
496. Pneumatic Tire Valves, G. C. Mesuard and G. G. Scurfield, Sunderland.
497. Cuff Suspender, J. M. L. Whitfield, near Huddersfield.
498. Grain Cleaning Machines, W. W. Willis, Ipswich.
499. Cuff and Shirt Ironing Machines, W. E. Baker, Aldershot.
500. Apparatus for Making Cheese, J. Helder, London.
501. Baby Chairs, W. S. McLennan, Glasgow.
502. Cycles of the Chain Driven Type, J. Cuncliffe, Manchester.
503. A Puzzle, A. W. and W. A. Turner, Birmingham.
504. Moving Grain, E. Banks and R. J. Miller, Liverpool.
505. Apparatus for Holding Coins, H. H. Hanmer, Liverpool.
506. Steering Cycles, A. Hamilton, London.
507. Screens for Photography, J. B. Findlay, London.
508. Reducing Collision, J. Thomas, Newcastle-on-Tyne.
509. Manufacture of Chimney Pots, S. S. Hazeland, Penzance.
510. Rudder Straps and Rods, L. J. Franklin, Isle of Wight.
511. A Horse Ball Instrument, T. Shell, Northumberland.
512. Driving Gear for Cycles, C. B. Lawson, Glasgow.
513. Attaching Wagons in Rope Haulage, R. B. Dick, Glasgow.
514. Apparatus for Drying Tea Leaves, J. A. Main, Glasgow.
515. Paper Files, R. Waldschmidt, London.
516. Using Lenses, G. J. Bull and B. F. C. Costelloe, London.
517. Pokerettes, T. R. Voce and B. Drysdale, Birmingham.
518. Washing Machines, J. W. Boot, London.
519. Fluid Meters, E. Hollanders, C. J. Leather, and T. Taylor, London.
520. Top Notches of Umbrellas, F. W. Chambers, London.
521. Cutting-out Garments, O. Stiassny and L. Lobl, London.
522. Bicycles and Tricycles, E. Eite and A. Todd, London.
523. Capstans, Davis and Co., Ld., and W. R. G. Hay, London.
524. Car Couplings, W. Silver, London.
525. Maid Servants' Caps, &c., A. T. Umfreville, London.
526. Gas Lamp Columns, J. H. Stevens and J. Tourtel, London.
527. Consuming Smoke, W. Smith and T. Lockwood, London.
528. Game, H. Fletcher, London.
529. Preparation of Artificial Musk, C. J. Caspers, London.
530. Seamless Metallic Tubes, W. Pilkington, C. T. Bishop, A. Brownsword, and A. Pilkington, Birmingham.
531. Tires for Carriage, &c., Wheels, C. Schwanitz, London.
532. Tires for Carriage, &c., Wheels, C. Schwanitz, London.
533. Telegraph Apparatus, Siemens Brothers and Co.—(*Siemens and Halske, Germany.*)
534. Shuttle Action for Looms, T. A. B. Carver, London.
535. Primary and Secondary Batteries, H. W. Headland, London.
536. Embroidery Frame, W. P. Thompson.—(*H. Rötter, Germany.*)
537. Cycle, &c., Wheels, E. C. Martin and A. Turrall, Liverpool.
538. Couches and Sofas, G. M. Weatherly, London.
539. Beer Engines, G. Watson and A. J. Foley, London.
540. Apparatus for Sewing Machines, F. Wilkinson, London.
541. Hydrocarbon Burners, L. E. Fraipont, London.
542. Treating Yarn, A. Monforts and A. Buckmann, London.
543. Alternating Current Apparatus, G. Hummel, London.
544. Tires, A. Steiner, London.
545. Speed Indicator for Locomotives, A. L. Pouget, London.
546. Electric Incandescent Lamps, &c., R. J. Bott, London.
547. Devices for Joining Cables, &c., H. Edmunds, London.
548. Lamps for Burning Liquid Hydrocarbons, The Lee Lamp (Parent) Company and J. C. C. Read, London.
549. Treating Gold or Silver Ores, W. Blackmore, Sheffield.
550. Quadrant Levels for Heavy Guns, A. Schriever, London.
551. Dynamo-electric Machines, L. B. Atkinson, London.
552. Water-bars for Casements, W. Youlten, London.
553. Casements, W. Youlten, London.
554. Attachment for Glasses, M. Foran, London.
555. Fire-places, E. P. How and G. H. Martyn, London.
556. Lamp Bracket, C. H. Ritchie, London.
557. Electric Batteries, R. Collins and F. Cogan, London.
558. Incandescent Mantles for Gas Lamps, J. H. H. Duncan, London.
559. Pillarless or Cantilever Cranes, J. R. Beaver, London.
560. Oil Engines, H. C. Bergemann, London.
561. Apparatus for Winding Cops, J. R. Leeson, London.
562. Gear Cases for Cycles, J. R. Trigwell and The Aluminium Cycle Fittings Company, Limited, London.
563. Tires, W. H. Jones, London.
564. Cocks and Valves, E. Z. y Guilirarti, London.
565. Transforming Continuous Electric Currents, H. H. Lake.—(*Cie de l'Industrie Electrique, Switzerland.*)
566. Applying Side Pressure to Ball Bearings, W. R. Smith, London.
567. Sight Testing Appliances, A. F. Schoerle, London.

9th January, 1896.

568. Game called "Salisbury Bat-catch," J. Samuel, Epsom.
569. Apparatus for Copying Tracings, B. J. Hall, London.
570. Composite Sash Weight, M. H., J. H., and W. F. Golightly, Hartlepool.
571. Bearings, J. Dewrance, London.
572. Prepayment Gas Meter Mechanism, D. B. Peebles, Glasgow.
573. Trapping and Killing Rabbits, J. H. Richards, Barnstaple.
574. Straining Pulp, D. N. Bertram and J. Blaine, Glasgow.
575. Air Rubber (Rupture) Truss, W. Graham, Enfield.
576. Locomotive, G. Bagnall and E. E. Baguley, Stafford.
577. Anti-ballooning Devices, J. Vaughan, Manchester.
578. Oil Engine, M. H. Hurrell and H. Jasper, Gillingham.
579. Manufacturing Chlorine Gas, J. B. Hilliard, Glasgow.
580. Seats, H. H. Farrell, Liverpool.
581. Latches, M. Sibbring, Liverpool.
582. Packing Blocks, H. F. Massey, Manchester.
583. Metallic Flasks, W. B. Challen and Taylor and Challen, Ld., London.
584. Tilting Saddle Bar for Velocipedes, C. Wooster, Glasgow.
585. Foot Cycle or Road Skate, R. and G. Anderson, Glasgow.
586. Rack for Golf Clubs, C. King, Glasgow.
587. Feed Bags, J. C. Meyers, Dublin.
588. Locking Apparatus for Gas Jets, T. A. Skelton, Southampton.
589. Finishing Woollen or Worsted Fabrics, W. H. Hare, Bradford.
590. Nuts, J. Whitehead W. Drysdale and M. Stoddart, Glasgow.
591. Tilting Barrels, G. Birkbeck and W. W. L. Lewis, Birmingham.
592. Safety Letter Delivery Apparatus, A. Powles, London.
593. Piano Stools, D. Anderson, Glasgow.
594. Fixing Ladies' Dress Guards, L. Lenton, Coventry.
595. Preparing Railway Guides, H. V. Vernon, London.

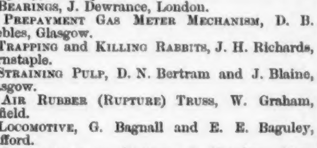
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

547,523. Cycle Wheel Adjustment, *A. Perkins, Chicopee, Mass.—Filed December 22nd*, 1893.

Claim.—The combination with the plates having the rearwardly open axle-receiving slots and the racks at their lower sides, of the threaded transverse axle, a stop upon said axle, the plate, upon the opposite side of the axle-receiving plate, bearing the worm gears engaging the racks respectively, and nuts upon the outer ends of the axle clamping the plates between the nuts and said stops.

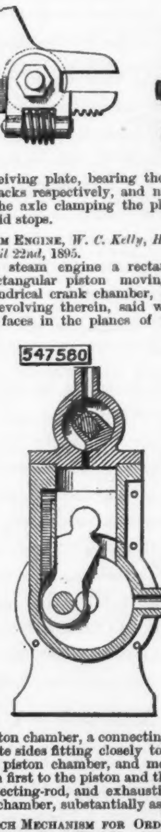
547523



547,580. Steam Engine, *W. C. Kelly, Hastings, Mich. —Filed April 22nd*, 1895.

Claim.—In a steam engine a rectangular piston chamber, a rectangular piston moving therein, a transverse cylindrical crank chamber, a crank and crank wheels revolving therein, said wheels having their opposing faces in the planes of the opposing walls of said piston chamber, a connecting-rod, having flattened opposite sides fitting closely to said wheels and walls of the piston chamber, and mechanism for admitting steam first to the piston and thence to one side of the connecting-rod, and exhausting the same from the crank chamber, substantially as described.

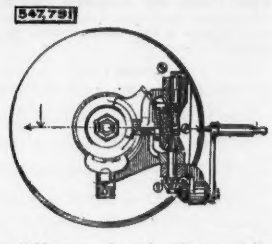
547580



547,791. Breech Mechanism for Ordnance, *O. F. Leibert, Bethlehem, Pa.—Filed May 19th*, 1894.

Claim.—(1) In a breech mechanism for guns, a breech block provided with a recess in its side, and a rack arranged in one side of said recess, in combination with a pinion entering the recess in the block and engaging the rack therein, substantially as described. (2) In a breech mechanism for guns, the combination with a breech block provided with a segmental rack and with a recess in its side having the rack arranged in one side of said recess, of a segmental gear engaging the segmental rack, and a pinion entering the recess and engaging the rack therein, substantially as described. (3) The combination with a breech-piece provided with a segmental rack and with a longitudinal rack, of a shaft having rigidly secured thereto a segmental gear and a pinion respectively engaging the segmental and longitudinal racks of the breech-piece, one of the teeth of the respective segmental gears being cut away, one of the teeth of the pinion being elongated, and the longitudinal rack being provided with a deep recess whereby the said gear and pinion may engage and disengage the said segmental and longitudinal racks at the beginning and end of their movements, and at the same time operate with freedom and be made strong, substantially as described. (4) The combination with a breech block having suitable gears, of a yoke piece supporting the tray to receive the block, a shaft carrying gears engaging the gears of the breech block mounted in the yoke and moving therewith, and operating mechanism for said gears, the arrangement being such that the block is rotated in and withdrawn from the breech on to the tray and swings with the yoke and tray while the operating mechanism is continuously moved in one direction, substantially as described.

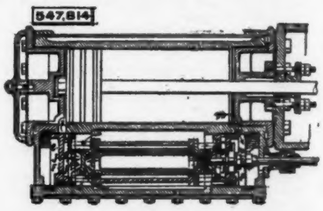
547,791



547,814. Valve for Steam Engines, *E. F. Spaulding, Bound Brook, N.J.—Filed August 17th*, 1894.

Claim.—(1) In a steam engine, the reciprocating valve, combined with the cylindrical cut-off valve carried thereby and having a movement independent thereof and reciprocating valve rod I connecting said reciprocating and cut-off valves, and adapted to turn axially and operate the latter, substantially as and for the purposes set forth. (2) In a steam engine, the reciprocating valve having the spaces *e* and longitudinal ports *h*, combined with the cylindrical cut-off valve seated within said reciprocating valve and having the longitudinal ports *j* and the reciprocating valve rod I connecting said reciprocating and cut-off valves, and adapted to turn axially and operate the latter, substantially as set forth. (3) In a steam engine, the reciprocating valve having the heads F, F, and cylindrical intermediate section, said heads having the spaces *e* and inner cylindrical portions provided with longitudinal ports, combined with the inner cylindrical cut-off valve having closed heads and beyond these the longitudinal ports, and the reciprocating valve rod I, connecting said valves and adapted to turn with the inner valve, substantially as set forth. (4) In a steam engine, the reciprocating valve having the longitudinal ports *h* and spaces *e*, combined with the inner cylindrical cut-off valve having the closed heads *i* and beyond these the longitudinal ports *j* and radial flanges H, substantially as and for the purposes set forth.

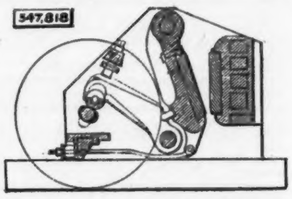
547,814



547,818. Rock-crushing Machine, *G. W. Taft, Kennett-square, Pa.—Filed April 15th*, 1895.

Claim.—(1) In a rock-crushing machine of the character described, the combination, substantially as described, with the movable or swinging jaw, and a vibrating jaw-actuating lever pivoted near said jaw, and connected therewith by a suitable bearing joint or toggle, the cam shaft, and cam engaging a roller at the free end of said jaw-actuating lever, of a non-movable support near the back of said lever, and a bump spring between said jaw-actuating lever and support disposed in disconnected relation to the surface against which it impinges, and adapted for contact, and action in opposition to the throw of the cam, by the lever movement, when at the outer limit of its vibration, for the purposes set forth. (2) In a rock-crushing machine the bump spring composed of india-rubber or elastic gum, the spring carrier having a flanged ring embracing said gum spring, and a supporting column threaded into the frame transom disposed at the back of the jaw-actuating lever, in combination with the jaw-actuating lever, the lever-operating cam, the movable crusher jaw, and means for retracting the crusher jaw, substantially as set forth.

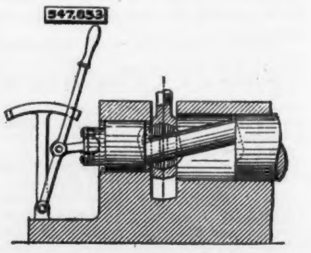
547,818



547,853. Adjustable Stroke Crank, *J. P. Johansson, Enkjöping, Sweden.—Filed June 21st*, 1895.

Claim.—(1) An improved means for varying the length of stroke of reciprocating parts of machinery, consisting of the combination of the following devices, namely, a shaft-box, a driving shaft free to be shifted lengthwise, a crank-pin at one end of such shaft and placed at an incline relatively to the axis of the shaft, a ball gudgeon in which this pin can be shifted longitudinally, a connecting-rod for the reciprocating part of a machine and having an end socket in which the ball gudgeon fits, said shaft-box having a guide recess to prevent shifting of this connecting-rod in the direction of the axis of the shaft, the combination being and operating substantially as and for the purposes set forth. (2) In combination, the shaft *a*, its shaft-box in which it may be shifted endwise and having a recess *e*, oblique pin *b*, gudgeon *c*, rod *d*, and pin *g*, all substantially as and for the purposes set forth.

547,853



THE WORLD'S PRINCIPAL WAR FLEETS.

THE excitement occasioned by the warlike message recently sent to Congress by President Cleveland in relation to the boundary question between Venezuela and ourselves, followed so closely as it was by a suggestion of German interference with our South African affairs, has necessarily directed the public mind to a consideration of our fitness to enter upon a war with any other great Power; and, as the chief source of Britain's strength must always be looked for upon the seas, attention has been chiefly centred upon the relative strengths of the world's principal war fleets.

In this connection it has been thought that the occasion is appropriate for a consideration, not only of what the war fleets of 1896 consist, but also of the development of vessels of war from the earliest time to the present day.

Unfortunately, very little is known regarding the war shipping of the early nations of the world. The first naval engagements of which history affords any detailed or trustworthy records were those between the Romans and Carthaginians, which resulted in the destruction of the Phœnician Colony on the African coast of the Mediterranean. Their war vessels were galleys propelled by one or more banks of rowers, the largest, or "quinquiremes," having five banks of oars on each side. In addition to the rowers, each galley carried a large number of soldiers, who fought their enemies in the opposing fleet with arrows, spears, and darts. The bows of some of the galleys were provided with beaks or rams, and in such cases they frequently attacked the ships of their opponents by ramming—a form of naval tactics which has been revived in modern days. Sailing ships were employed in the naval wars between the Romans and Venetians, but galleys were to be found in the European navies so recently as the seventeenth century. The Mediterranean Sea was the birth-place of naval enterprise, and continued to be the chief scene of naval exploit for more than a thousand years after the Christian era.

The Scandinavian nations were, however, from an early period noted for their maritime prowess; but their activity on the seas was in most cases of a predatory character. The British Isles were the scene of their ravages during the ninth century, and it was with a view to repel their frequent attacks on our shores that King Alfred collected the first English fleet. To check the same marauding foe William I. established the Cinque Ports, granting them certain privileges upon the condition that they furnished fifty-two ships, each with twenty-four men, for a period of fifteen days' service in the event of an attack from these northern raiders. From that time until the seventeenth century the sovereigns of England continued to make levies of ships and men from the mercantile marine to assist in the defence of the kingdom, and a similar practice prevailed in other European countries. A fleet of Edward the Confessor in 1049 is said to have consisted partly of "King's ships" and partly of "people's ships." It is recorded of Edward III. that he blockaded Calais with 730 sail, having on board 14,956 mariners, of which fleet only 25 ships, with 419 mariners, belonged to the Royal Navy. Under Henry IV. and Henry V., the strength of the national fleet was much increased, and the latter monarch is reported to have embarked an army of 25,000 men at Dover on board 1500 sail of ships.

In the early English fleets there were numerous classes of ships, the largest of which, known as "cogs," were of only 250 tons, but each carried 130 seamen, besides archers and soldiers. Of the other classes there were "barges," "balingers," "caraks," "crayers," "doggers," "fluves," "galleys," "galliots," "pinnaces," &c. In the reign of Henry VIII. great improvements were made in the construction of warships, and the Great Harry, built in this reign, is the first recorded ship of war which deserved that name. Her cost was £14,000, which at that period represented a very large sum of money. England's Royal Navy first assumed considerable proportions under the same monarch, and in the thirteenth year of his reign it contained the following ships, besides eleven others of lesser size:—Henri Grace à Dieu, of 1500 tons; Gabriel Royal, of 650 tons; Mary Rose, of 600 tons; Sovereign, of 800 tons; and Great Galley, of 800 tons. The total tonnage of the Royal Navy at that time was 72,600 tons.

The recorded details of the Henri Grace à Dieu are of interest at this time. She was built at Erith in 1512, carried 14 guns on the lower deck, 12 on main deck, 18 on quarter deck and poop, 18 on a lofty forecastle, and 10 in stern ports; or 72 in all. Her complement was 349 soldiers, 301 seamen, and 50 gunners; or 700 men in all. War vessels of this period, as represented in contemporary paintings, were of cumbrous and towering proportions. Their lofty forecastles, poops, and quarter decks must have seriously impeded both speed and manœuvring under sail, and their general appearance was not unlike that of the modern Chinese war junk. The Royal Dockyards at Deptford, Woolwich, and Portsmouth date from this time, and Henry VIII. also founded the Trinity House. At the death of that king the Royal Navy of England consisted of 50 ships and vessels, the largest being of 1000 tons.

The first claim to our naval supremacy was made in the reign of Mary, whose Lord High Admiral insisted upon the fleet of Philip of Spain, consisting of 150 sail, striking their colours and lowering their topsails to the English flag before he would permit his squadron to salute the Spaniards. The defeat of the Spanish Armada in the following reign contributed materially to enhance our naval prestige, and to develope the ardour and enterprise of our seamen. The Spanish Navy was superior to our own in numbers, and in the size of its ships; but their top hamper interfered with their management, and so they became an easy prey to the smaller ships of the English fleet, which cut off individual vessels in the Armada, and destroyed or captured them singly. Moreover, the same defects in their construction will account for so many of the Spanish ships being wrecked through the storms which they encountered in sailing round the British Islands. Such defects were, however, characteristic of the war shipping of the time, and it was not until the reign of James I. that these towering outworks were reduced in the vessels of our own Navy. It is to Phineas Pett, a naval constructor of that time, we owe the first essential improvement in the form and construction of our war shipping. In 1610 Pett laid down the Prince Royal, of 1400 tons, which was 114ft. in length of keel and carried sixty-four guns, "being in all respects," says Stowe, "the greatest and goodliest ship that was ever built in England." Pepys says that in 1618 there were thirty-nine ships in the Royal Navy of 14,700 tons, and six years later the Navy consisted of 33 ships of 19,400 tons, showing that the average tonnage of war shipping was increasing. Charles I. added upwards of 20 ships to the Royal Navy, and Pett built for him the Sovereign of the Seas, of 1637 tons, at Woolwich in the year 1637. Her length of keel was 128ft.; length over all, 232ft.; and breadth of beam, 48ft. She had three decks, forecastle, half deck, quarter deck, and round house; from which data and her great length over all it will appear that the projecting head and lofty poop had not wholly disappeared in warships. Upon comparing an existing painting of this ship with a drawing of the Henri Grace a Dieu in the Pepysian collection, the great improvement in naval design which had been effected during a century is clearly apparent. The Sovereign of the Seas carried 98 guns on her broadsides, besides 20 bow and stern chasers, and smaller ordnance for sweeping her decks of boarders.

During the Commonwealth England was for five years at war with Holland, which at that time was the greatest European Naval Power. Our fleet was increased to 150 ships, many of which were captured from the Dutch, and the Royal Navy then contained 20,000 seamen, so that our naval strength was greater then than it had ever been before. The type of warship known as a "frigate" was added to the fleet by Cromwell; the first, named the Constant Warwick, built by Peter Pett—a son of Phineas —in 1640, being copied from a French frigate which visited the Thames. The French supplied us with models for our ships during more than a century after that time. Indeed, the courage and skill of our seamen contributed much more towards establishing our naval supremacy than the scientific ability of our shipbuilders.

In the early part of the reign of Charles II. the Navy continued to increase, and in 1679 it contained 76 ships of the line in good condition, and at one time there were 30 new ships building. Sir Anthony Deane was placed at the head of our naval construction in 1686, but that eminent naval architect thought it desirable to imitate the best French models, such as the well-known Superbe, of 74 guns. In 1688, when William of Orange landed in this country, the Navy consisted of 173 sail, amounting to 101,892 tons, carrying 6930 guns, and with a complement of 42,000 seamen. William founded the civil government of the Navy, and so augmented our naval strength that at his death it consisted of 272 ships of 159,020 tons. At that time we had 130 ships of the line, and this force was maintained until the middle of the eighteenth century.

At the death of Queen Anne the Royal Navy consisted of 247 ships of 167,219 tons, showing that the average size of our warships continued to increase. George I. left the Navy nearly as he found it, viz., 233 ships of 170,862 tons. In 1739, when George II. was at war with Spain, it was ordered that ships of the line should be enlarged in size, and on the restoration of peace in 1748 it was found that 35 of the enemy's ships of the line had been captured, with a very trifling loss to ourselves. At the king's death in 1760, the Navy consisted of 412 ships of 321,104 tons. Upon the conclusion of the American war in 1783, the naval force of the country amounted to 617 sail, measuring 500,000 tons, and at the peace of Amiens the Navy consisted of 700 ships, of which 144 were of the line. The number taken from the enemy amounted to 600, of which 90 were of the line and upwards of 200 were frigates. Our loss during the war was 60, of which 6 were of the line and 12 were frigates.

From 1808 to 1813 there were seldom less than 100 to 106 sail of the line in commission, 130 to 160 frigates, and numerous smaller vessels; our total naval strength being about 800,000 tons.

A printed return, dated January 1st, 1821, shows that the Navy then consisted of 609 sail of the line and vessels, as under:—

	Number.
First rate, from 120 to 100 guns	23
Second rate, from 86 to 80 guns	16
Third rate, from 78 to 74 guns	90
Fourth rate, from 60 to 50 guns	20
Fifth rate, from 48 to 22 guns	107
Sixth rate, from 34 to 24 guns	40
Sloops, from 12 to 10 guns	136
	432

to which were added 177 vessels, consisting of gun brigs, cutters, sloops, tenders, &c.

In 1836 the total number of our ships of war was 560, of which 95 were ships of the line in good sea-going condition. In 1846 it had reached 671 ships, and in 1857, 735 ships.

Of the war fleet of the United Kingdom in 1859, 110 were ships of the line ranging from 131 guns to 84 guns, and 124 were frigates of from 50 to 36 guns. Sixty-four of the line-of-battle ships and 98 of the frigates were propelled by steam power. Fifty-seven of the line-of-battle ships and 31 of the frigates were in commission. In addition to the foregoing, there were 64 paddle frigates and sloops of from 22 to 3 guns each, and of these 46 were in commission. Many of the ships which were on the Navy List in 1857 had by this time been struck off in consequence of their age and defects.

This brings us down to what may be termed the modern era of war shipping, for from about that time dates the introduction of armour plating, and the commencement of that rapid series of naval developments which result in a warship being obsolete almost before she is completed for sea.

The following is a statement of the strength of the world's principal war fleets in the year 1859:—

	Ships
United Kingdom	711
France	448
Russia	164
Sweden (principally small vessels)	311
Norway	143
Denmark	120
United States	79
Holland	139
Belgium	7
Spain	82
The Two Sicilies	121
Austria	135
Portugal	37
Sardinia	28
Prussia	55
Greece	26
Turkey	49
Brazil	27
Peru	15
Chili	5
Mexico	9

Before considering that series of changes in naval design, and the long list of ships which have been built for the world's war fleets during the past thirty-five or forty years, it is desirable that something should be said regarding the ordnance that was carried by European war shipping from the time of the invention of cannon to that of the Crimean war.

Warships were first armed with cannon so early as the year 1338, and about the year 1372 guns and gunpowder were in common use for war purposes. The armament of the Christopher of the Tower, in 1338, included three iron cannon, of which each had five chambers, and that of the Mary of the Tower included one iron cannon with two chambers, and a brass cannon with one chamber. The weight and calibre of these pieces of ordnance is not recorded, but the projectiles fired from those with more than one chamber were doubtless of small size. At the latter part of the fourteenth century naval ordnance consisted of cannon, which are supposed to have been 60-pounders; demi cannon, 32-pounders; culvers, 18-pounders; falcons, 2-pounders; mynions, 4-pounders; and sakers, 5-pounders.

At the battle of Chioggia in the year 1380, fought between the Venetians and Genoese, guns named "bombards" were employed, which were formed iron rods bound together with hoops of the same material, and the spherical projectiles fired from these were of stone, weighing from 140 lb. to 195 lb. Stone shot of even larger size were used by the Turks in the defence of the Dardanelles early in the present century, and the celebrated Mons Meg, which is still preserved at Edinburgh Castle, is a specimen of large ordnance built with wrought iron bars and hoops, in the manner adopted in the fourteenth century. A similar gun is in Ghent.

The armament of a Maltese galley of about the beginning of the fifteenth century consisted of one 36-pounder, two 24-pounders, and twelve 6-pounders. A Swedish ship, named the Makalos, which was burnt in an action with the Danes in 1564, mounted 173 guns, 67 of which were cannon, and the remainder were small swivel guns; but the weight of their projectiles is not known. It seems, however, that 68-pounders were the heaviest guns in ordinary use on shipboard until comparatively recent times, the great bulk of the ordnance consisting of 32-pounders, 20-pounders, and smaller guns. Indeed, so recently as the year 1857, an eminent naval authority in this country reported his opinion that "our 95 cwt. 68-pounder is probably as heavy a gun as can be worked with facility on board of a ship." Certain it is that Nelson fought his battles with guns of much smaller size, the 32-pounders being considered heavy ordnance in his time, and up to the year 1860 the cast iron 95 cwt. 68-pounder smooth bore gun was the largest ordnance carried in the Royal Navy. Most of the guns captured from the Russians in the Crimean war were 32-pounders, or thereabout.

It was shortly before the war with Russia that explosive projectiles were introduced, and our experience of their effects dates from that time. The use of shell led to the adoption of armour-plate protection, and the floating batteries which were built by England and France during that campaign were the parents of the world's armour-clad fleets.

In what has been said regarding the world's war navies up to the year 1860 attention has been directed almost wholly to the fleet of Great Britain. It is to be regretted that complete statistics are not at hand showing the gradual growth of the naval Powers of Spain, Holland, France, and other countries during the time that the United Kingdom was winning her way to that proud position of maritime supremacy which she attained rather more than a century ago.

Under the Duke of Burgundy in the fifteenth century, the Netherlands—which until then were scarcely known—became the most formidable naval Power in the north of Europe. "His navy was so mighty and strong," says Philip de Commines, "that no man durst stir in the narrow seas for fear of it—being stronger than that of France and England together." Venice in 1420 supported 3000 merchant ships, on board of which were 17,000 seamen. She employed 300 sail of superior force, manned by 8000 seamen; had 45 carracks, with 11,000 men to navigate them, and her arsenals employed 16,000 carpenters.

After the Portuguese had pushed their discoveries around the Cape of Good Hope to India, and Spain had discovered the continent of America, these two Powers made rapid strides in naval construction, building ships of much larger size than before, in order to meet the requirements of their distant voyages. The Spaniards were the first to build a warship mounting three tiers of guns, and thereby laid upon the English Government the necessity of constructing larger and more powerful ships than had hitherto been built for our Navy. During the early part of the seventeenth century the Dutch navy increased rapidly in importance, and they succeeded in wresting a share of both the Portuguese and Spanish commerce. In 1650 their fleet was in all respects the most efficient in Europe.

The navy of France in 1661 consisted of only four or five vessels, yet Louis XIV. and his minister Colbert, in little more than ten years created a Navy which baffled the combined fleets of Spain and Holland, and claimed the mastery of the Mediterranean. In 1681 the French navy consisted of 115 line-of-battle ships, manned by 36,440 seamen, besides 179 smaller vessels; while in 1690 a French fleet of 84 vessels of war, of which 3 were of 100 guns and upwards, and 10 others each above 84 guns, with 22 fire ships, was cruising in British waters. But although the struggle was a severe one the Navy of Britain succeeded in triumphantly asserting its superiority. The French were, however, able naval constructors, and the successes of the British Navy were due rather to our seamen than to our ships. Throughout the wars of the time of George III. our ships were inferior in sailing qualities to those of France and Spain. It was not, indeed, until the commencement of the present century that the British Admiralty called to its aid the same scientific skill as had hitherto been devoted to naval construction on the Continent.

Although the possibilities of steam navigation had been demonstrated for some time previously, it was not until the year 1843 that steam machinery was fitted in ships of large size in the Royal Navy. In that year the frigate Penelope of 46 guns was cut down, lengthened, and supplied with engines of 650-horse power; and in 1846 two screw frigates — the Arrogant and Dauntless — were built in the Royal Dockyards. By the year 1859 a large part of the Royal Navy was propelled by steam power, as shown by the foregoing abstract of that date. Shortly before the Crimean war, and for several years after the conclusion of hostilities with Russia, all the wood vessels built for the principal European navies were designed with a view to screw propulsion; but many of the later constructed screw vessels of the Royal Navy were never commenced nor even rigged for sea, in consequence of the introduction of armour-clads, which speedily rendered obsolete all former types of ships for line-of-battle service. The necessity for this means of protection against shell fire has already been alluded to, as well as the means adopted by England and France in the form of iron-plated floating batteries for resisting the fire from the Russian forts. The floating batteries were speedily found insufficient to meet the wants of the case, and the ironclad frigate La Gloire, commenced by the French Government in 1858, was the first armour-clad ship fit for seagoing purposes. The construction of the sister vessels, Invincible and Normandie, was at once commenced, and they were quickly followed by the Couronne. The British Admiralty found itself compelled to follow in the same direction, and shortly before La Gloire was launched the Warrior was laid down at Blackwall. But while the French armour-clads were constructed of wood, the Warrior, on the contrary, was built of iron, and in that and many other most essential particulars she was more truly the progenitor of the world's armoured fleets than the French vessel; for, except in so far as their rigging was concerned, these latter were no great step in advance of the original floating batteries. The Black Prince, a sister to the Warrior, speedily followed, and soon after them the Defence and Resistance—all of iron—were laid down. In 1861 the British Admiralty decided to cut down to frigates and to armour plate several of the wood line-of-battle-ships then upon the stocks and in a state of great advancement; also to build the Achilles, Minotaur, Agincourt, Northumberland, Hector, and Valiant of iron. During this time the French had built the Solferino and Magenta, and in 1862 they laid down ten frigates of the Gloire type, but with thicker armour.

It will thus be seen that at the commencement of the sixth decade of the century there occurred a remarkable revolution in naval construction, accompanied by great activity at the dockyards of the two principal naval Powers in the world, so that in a brief space of time the pre-existing enormous navies of both Powers were rendered practically obsolete. From that time until now the ingenuity of naval architects has been continually directed towards the attainment of an ideal "ship of the future," which shall occupy the same position in future war fleets as was occupied for about two centuries by the wooden line-of-battleship and frigate.

The simultaneous development of naval ordnance, the introduction of ramming tactics, the invention of the torpedo, and other similar offensive weapons, has, however, made impossible the attainment of finality in naval design. When the French built the Gloire and we laid down the Warrior, it was generally supposed that the 95 cwt. 68-pounder gun was the most formidable weapon that fleets would have to cope with, and the thickness of armour plating adopted in the earliest ironclads—viz., 4in. to 5in.—was considered sufficient to resist the projectiles from that gun, and so secure immunity against the much dreaded shell. But when the armour-plate was found capable of resisting existing guns, ordnance manufacturers set to work to construct more powerful ordnance. To trace the successive steps by which the 95 cwt., 68-pounder, cast iron, smooth bore, muzzle-loading gun has been succeeded by the wrought iron 80-ton muzzle-loading rifled gun of the Inflexible, and the 111-ton gun of the Benbow, to say nothing of the 13½in. 67-ton breech-loaders of the Ramillies, and the 12in. 45-ton guns of the Jupiter, would occupy more space than is at our dispoal. It must be sufficient to say that, thanks to the skill of Armstrong, Lord Rendell, Sir J. Whitworth, the Government staff at Woolwich Arsenal, Colonel Palisser, and others in this country, together with that of Krupp and others on the Continent, the progress of ordnance manufacture has been most rapid, and the results stand in marked contrast with what had been done during several preceding centuries. In the Royal Navy at the present day a gun of 9 tons is considered small; those of 12½ and 18 tons are quite common, while the most formidable of our armour-clads are armed with ordnance of 29, 38, 45, 67, 80, and even 111 tons.

As the gun had increased in size and power, naval architects have sought to clothe ships with armour capable of resisting it. The earliest ironclads, as already stated, were plated with 4½in. to 5in. armour. In 1862 the last named thickness had not been exceeded; but in 1863 the Bellerophon was designed by Sir E. Reed to carry 6in. armour upon 14in. teak backing. The Hercules, laid down by the same eminent constructor in 1867, had 9in. armour plates upon her sides. The year 1872 saw 14in. armour plates being fitted to ships of war, and two years later the Inflexible was designed to carry 80-ton guns, and be plated with 24in. of iron armour. Later on, guns were increased to 100 tons, and an equivalent of 18in. of compound iron and steel armour substituted for the 24in. of iron. During recent years our naval constructors have contented themselves with less heavy ordnance than formerly; but, by reason of the superior strength of the modern steel guns, their penetrative efficiency is fully equal to that of the heavier wrought iron ordnance so much in vogue about ten years ago. Just now another important advance is being made in the manufacture of armour plates from nickel steel, and in the application of the Harvey process for hardening the face of the armour for some distance from its surface. "Harveyed" steel armour of 14in. in thickness is found to offer an equal resistance to penetration by chilled projectiles as that of armour of 18in. to 21in. in thickness which has not been so treated. The 24in. armour of the Inflexible seems to have reached the limit set by the buoyancy of ships of ordinary size, and the requirements in regard to the extent of surface which should be protected.

While the growths in naval construction already referred to were taking place in the British Navy, other nations were not inactive, nor did they at all times permit us to take the lead in the inventive skill brought to bear upon the subject. For a long time the French continued to build armour-clads of wood, but, finding that they rapidly decayed, it was ultimately decided by them to resort to iron and steel. In the year 1874 the last-named material was being largely used in the French dockyards, notwithstanding that failure had in most cases attended our efforts up to that time in the employment of steel both at our royal and private shipyards. Encouraged by the partial success of the French workmen, our naval constructors appealed to steel manufacturers for a more trustworthy steel for ships' construction than had hitherto been supplied, and in response to that appeal the material known as "mild steel" was produced. The committee of Lloyd's Register of Shipping made numerous experiments upon the new material, and very speedily it was accepted by them and the Admiralty. From the year 1875 dates the construction of the steel fleet of steam and sailing vessels of the mercantile marine, and the adoption of the same material for all parts of a warship.

The first ironclads were ordinary broadside frigates, having their sides protected by comparatively thin armour-plates to a few feet below the water-line. The increase in the thickness of armour which soon followed rendered it necessary to limit the area covered by that protection. No sooner was the application of armour limited to certain parts of the vessel than at once there arose a great variety of conflicting views regarding the best possible use which could be made of it. It is scarcely possible to better classify and describe the several systems of armour protection which have been adopted in the world's war fleets than in the language of Sir Nathaniel Barnaby, who preceded Sir William White as Director of Naval Construction at the Admiralty. Sir Nathaniel says:—"Of protected ships there are many varieties. (1) The ships of the Comus class, *i.e.*, corvettes of 2300 tons displacement. They have an under-water steel deck wrought over the engines, boilers, and magazines, with a raft body above it. . . . . . (2) The ships of the Warrior type. These are divided into three parts longitudinally. There is a middle division, varying between one-half and three-fifths of the whole length of the water-line, which has a belt of armour on the sides and ends, and there are two end divisions protected by an under-water deck, as in the Comus, but without a raft body. . . These ships then have, as above stated, three divisions, viz., side armoured middles and protected ends. (3) There is the ship protected by side armour throughout the water-line, associated with a short or with a long and conterminous armoured battery overhead. In the latter case the ship is said to be completely protected, in the former only belted; but in neither of these cases is there a protecting under-water deck. This class includes nearly all the completed ironclads of all navies, and all the protected ships designed in England between 1861 and 1873. (4) There is the ship protected by side armour on a middle division of the ship, associated with protected ends and raft bodies. In this division is included the Inflexible, Ajax, Agamemnon, Nelson, and Northampton, the Duilio, Dandolo, and the German ships—five in number—of the Sachsen type. (5) There is the ship with protected deck and raft bodies from end to end, without side armour, but with armoured batteries, to which it has been understood that the Italia and Lepanto are to belong, but of which there is no actual representation at present."

Since Sir N. Barnaby wrote this classification of the world's armoured shipping, many advances have been made. The torpedo has now a more active existence than in those days, and the quick-firing machine gun has become one of the most important elements in the armament of both armoured and unarmoured ships. Take, for example, the case of the Ramillies recently built on the Clyde. This powerful battleship is of 14,150 tons displacement, she has 18in. and 14in. compound armour on her sides, 17in. compound armour on her barbette towers, and 3in. protective deck armour. Her armament consists of four 13½in. 67-ton breech-loading steel guns, ten 6in. guns, twenty-eight quick-quiring 6-pounders and 3-pounders, eight Maxim guns, and seven tubes for discharging torpedoes.

The Jupiter, now in course of completion, has a displacement of 14,900 tons, Harveyed armour fully equal to the compound armour of the Ramillies, four 12in. breech-loading rifled guns, twelve 6in. guns, sixteen 12-pounder quick-firing guns, twelve 3-pounder quick-firing guns, and five torpedo tubes. These figures will serve to show that in the modern battleship something more is provided for than the pounding of an enemy's armoured sides, all important as that function undoubtedly is. Regarding the unarmoured ships of the British and other navies, it is impossible to give a detailed account in consequence of the great number and the diversity of their types. Some are for cruising, some for dispatch carrying purposes, and others for ordinary service upon distant stations, while others, again, are designed wholly with a view to being employed in torpedo attack. In all these types and classes steel is the material now used, and the improvements effected in recent years with the marine engine and boiler have resulted in far higher speeds and greater coal endurance than was found possible at an earlier date.

An exact comparison of the strength of the world's principal war navies is not possible from a mere statement of the number of battleships, or first or second-class cruisers, &c., &c., in each, for authorities do not agree in regard to the specific value which should be assigned to each of the several functions of a warship. The basis of displacement does, however, afford a rough means of comparing war vessels of the same type, for it is on their buoyant capabilities that the maximum weight of their armour, guns, machinery, coals, ammunition, stores, &c. depend. At the same time, it must be remembered that designers of different skill and experience will appropriate the displacement at their disposal in very different ways. The earlier armour-clads are, ton for ton of displacemant, much less efficient than those of more recent date.

Using the displacement in tons as a basis of comparison, it appears that the relative extent to which Great Britain, France, Italy, Germany, Russia, and the United States have provided themselves with the several powerful classes of warships is as follows:—

Details of the World's Principal War Fleets.

	Seagoing armour-clads and belted cruisers.		Coast defence armour-clads.		Protected cruisers.		Torpedo vessels.		Torpedo boats.		Other unprotected vessels.	
	Ships.	Tons displacement.	Ships.	Tons displacement.	Ships.	Tons displacement.	Ships.	Tons displacement.	Ships.	Tons displacement.	Ships.	Tons displacement.
Great Britain ...	70	676,800	16	61,710	87	390,535	89	71,560	165	7923	156	160,314
France	49	409,400	18	53,775	28	106,035	58	32,356	206	8434	118	193,562
Italy	17	161,880	5	22,860	22	76,885	20	11,639	151	9877	53	69,259
Germany	14	113,557	21	41,840	4	18,850	21	17,450	144	9043	39	63,824
Russia	31	259,540	24	55,800	2	8,150	13	5,544	178	4283	64	59,015
United States ...	8	72,100	21	56,830	16	64,860	4	1,067	4	40	23	29,450

It must not be supposed that the displacement criterion is sufficiently accurate to enable an exact comparison to be made by means of the foregoing table between the strengths of the several fleets named upon it. For instance, of the 21 coast defence armour-clads credited to the United States, 13 date back to the close of their civil war, and are obsolete; and of the 49 seagoing armour-clads in the French Navy, 12 ships of 80,740 tons are built with wooden hulls. Then, again, although we have fewer torpedo boats than France or Russia, and with a relatively less displacement than Italy or Germany, yet it must be remembered that our enormous fleet of torpedo vessels, including the "destroyers" of the Hart and Handy class, serves all the purpose of torpedo boats, and in far more efficient manner. Thanks to the vigorous action of recent administrations—both Radical and Unionist—our fleet is at present stronger in relation to the navies of other Powers than it has been at any time during fifty years before. The efficiency of our Admiralty and Dockyard organisation, and the preparedness of our ships, are evidenced by the promptitude with which the most powerful flying squadron that ever left our shores has been collected and equipped for sea.

THE Lake Erie Ship Canal plans and estimates have been submitted to the consulting engineers, General H. L. Abbott, Major N. H. Hulton, and Professor L. M. Haupt. While no formal report has been made as yet, the Pittsburg *Dispatch* says the following conclusions have been practically arrived at: A 15ft. canal with 340ft. locks would accommodate the bulk of the vessels now engaged in lake traffic; the summit-level water supply, even during drought, is sufficient for a canal with a freight capacity of 13,000,000 tons annually, and this capacity can be increased if the canal is deepened. The railway-bridge crossing question is still in the hands of the engineers; the preliminary estimate of £5,400,000 to £6,000,000 is not far from the expected cost. A canal of 8ft. or 10ft. is impracticable, according to General Abbott, because it would have to be deepened in a few years.

CONSTRUCTION OF MODERN LIGHTHOUSES.

TIMBER, stone, iron, both cast and wrought, and steel have all been employed in the construction of lighthouses. The first of these materials needs no further consideration, although it may be mentioned that exactly two hundred years ago the first Eddystone Lighthouse was built of it. It was swept away in a tremendous storm four years after its completion, and another, chiefly of timber, but with a stone base, was erected in 1708. This structure appears to have been fairly equal to the occasion, for, although repaired at intervals, it stood firm for nearly fifty years, when it was destroyed by fire. In foreign countries, where timber of large scantlings is cheap and readily procurable, it is still adopted as the material for the building of lighthouses; but the examples are not of any magnitude, and seldom placed in a very exposed situation. The erection of the new Eddystone Lighthouse in 1882, and the building of the new Putney Bridge, both of stone, are proofs that iron and steel, however much they may have trenched upon the ground originally occupied by the older material, have not succeeded, and probably never will, in superseding entirely the employment of it in two of the most important works of the architect and engineer. Numerous additional instances could be mentioned in which the solid stone has successfully held its own, but the two modern ones quoted will suffice for our present illustration. In connection with this subject, it must be borne in mind that Smeaton's lighthouse—the predecessor of the present one—was stable, sound, and durable to the last. It was not in any way damaged or destroyed, but was purposely taken down in consequence of the slow but sure disintegration of the rock upon which it was founded. As a monument to its great designer, it can be seen on the esplanade at Plymouth, where it has been re-erected to his honour.

Whether it be true or not that Smeaton took the idea for the contours or form of his tower from that of an elegant and graceful tree, the fact remains that modern stone lighthouses are not built in accordance with that standard. We are not asserting that Smeaton was wrong in his views. In fact, we could not with a due regard for the excellence and stability of his great work. But since his time different, and perhaps more advanced, opinions are now held, which have led to the adoption of another profile for these life-saving beacons, as will be subsequently pointed out. It should also be stated that our knowledge of the action of waves, and their effect upon obstacles and impediments to their motion and violence, has been enormously augmented since the days of the first Eddystone, properly so called. By selecting the tree-form for his tower, the designer probably intended, not so much to resist the action of the waves as to allow them to expend their force in a vertical direction after striking the base of the shaft. Instead of resisting or repelling them, they were induced or coaxed to run up the smooth, sloping exterior of the structure, and, after exhausting their fury, fall harmlessly on the rock or in the waters below.

The height to which the waves reached depended principally upon the state of the weather and the condition of the tide. Waves "mountains high" have frequently been alluded to, but, however strongly they may appeal to the poetical and the imaginative, they will not bear the test of actual experience. At the Wolf Lighthouse the height of the loftiest waves was frequently observed with great accuracy and precision, and it was fully and incontestably established that the highest did not rise more than thirty-two feet above sea level. As the ridge of a wave above sea level is about equal to the depth of the furrow below the same datum, the total height of the wave of maximum altitude in the neighbourhood of Land's End would amount to some sixty-five feet. It should, however, be stated that there is no reason to doubt that the assertion that the waves at the Bishop's Rock Lighthouse have on rare occasions reached a maximum elevation of one hundred feet is not perfectly accurate and trustworthy.

One of the first improvements in the construction of modern lighthouses of stone was adopted in the building of the present structure at the Eddystone Rock. Instead of offering a sloping plane for the waves to run up directly they came in contact with the solid masonry, and ultimately temporarily obscuring the rays of the lantern, they were fairly encountered and resisted at the very base of the edifice. The original form of Smeaton was completely changed, and the contour of the base or pediment was built on vertical instead of inclined lines. Up to high-water mark, and a certain distance beyond it, the lower part of the structure was erected plumb from the surface of the natural rock. The object of this new and improved design was to break the force of the waves, to receive and resist their impact by the weight, mass, and *vis inertiæ* of the solid stonework opposed to their violence. A certain portion of the waves, when there was a violent sea on, no doubt did run up the tower, but to a comparatively very small extent, the larger part being, as it were, reflected and thrown back into the turbulent waters beneath. If this principleof constructionbe adopted, as it no doubt will be in all future solid stone structures of the description under notice, it is an example of meeting and overcoming violence, or action, by simple equal reaction. In describing the structure as solid stone work, we are referring only to the lower part of it which is within, and also for obvious reasons some distance above the striking power of the waves. That part of the lighthouse above the impactive violence of the waters has only to withstand the fury of the wind and elemental disturbances It must also perforce be sufficiently hollow and capacious to contain the inmates and their belongings, together with stores, provisions, and the necessary tools and appliances for keeping the machinery and light in proper and efficient order. This task is by no means so easy as might be imagined, as a visit to a lighthouse will speedily demonstrate.

The older and the more modern contours adopted for the designs of stone lighthouses differed briefly in the fact that the former had no vertical base, which was subsequently bestowed upon the latter. There is a close resemblance between the modern form or profile adopted in the recently built Eddystone Lighthouse and that erected in 1887 at the Bell Rock. This structure was not altogether a new one, but was an improved form, embodying an outer wall or casing of stone, dowelled and dovetailed both vertically and horizontally into the granite courses of the original building, from the foundation level to a height where the shaft necessarily becomes hollow, for the purposes already mentioned. Above this level the old work was pulled down and entirely reconstructed, the whole tower attaining a height of nearly 150ft. to the focus of the lantern, or nearly 40ft. higher than the first design. A comparison of the two principles and two profiles already described will at once indicate the different manner in which the force of the waves is dealt with in the two structures, and also the superior advantages with respect to greater stability, permanence, and security which is endorsed by the adoption of the larger vertical cylindrical base. It is this part of the building that is most exposed to the greatest violence of the waves and requires to be the strongest. The vertical base not only throws back the billows, but widens out the foundations from which the tower springs, and, moreover, lowers the centre of gravity of the whole mass. This last consideration is very important in connection with the safety and the future stability of the tower, as a low centre of gravity tends to diminish the propensity to rocking in a gale of wind, shared by all lofty and comparatively slender edifices. It is not at all uncommon for a high chimney stack to deflect laterally at the top 8in. or 9in. The motion, although not visible to an unpractised eye, can be readily perceived through a theodolite or transit instrument, and measured if required.

In imitation of lighthouses built of stonework, iron has been employed with brick lining, but the more modern type includes the open or braced form. The principle governing designs of this character is essentially distinct from that we have described in the present article, but they have many special features which recommend them for adoption in situations where the erection of a lighthouse of stone would be well-nigh impracticable. It should, in fact, be stated that, previously to the building of the stone lighthouse at Bishop's Rock, which was subsequently strengthened, altered, and partially rebuilt to constitute the present structure, a lighthouse of cast and wrought iron had been put up on the same site. It consisted of a hollow central column, flanked by six smaller on the outside, so as to form a regular hexagon on plan. The six columns were secured to the central or main columns and to one another by the usual diagonal bracing of struts and ties. From the level of high water at ordinary spring tides, the height to the lantern was 96ft. The construction, although tedious and difficult, proceeded satisfactorily until the tower was ready for the placing in position of the lantern and its accessories. In this condition it was left to the mercy of the winds and waves of the impending winter. Fortunately no one was deputed to inhabit it, for one night a furious storm arose, and swept it clean away, leaving nothing of it visible next morning but the stumps of some of the iron columns. The catastrophe was attributed to the fact that the height to which the waves might rise had not been correctly estimated, and that they reached an elevation which enabled them to strike the large area or surface of the shaft intended for the abode of the keepers and the reception of the general stores. In other words, the waves, instead of passing under and through the open part, struck against the sheeted sides higher up. It must be borne in mind that this disaster occurred nearly fifty years ago, and engineers were at that time but very indifferently acquainted with either the theory or practice of open-sided structures of any description. This failure must not, therefore, according to the maxim *ab uno disce omnes*, be regarded as condemnatory of all open-sided lighthouses built on similar lines. Experience has abundantly demonstrated their value and suitability for their duties, and notably in situations where for many reasons, independently of the cost, the erection of a stone lighthouse would be out of the question. A very fine example of the open cast iron columnar design, octagonal in plan, has been recently erected at Cape Charles in the United States. It has a total height from the foundation to the lantern of 176ft., and of 200ft. to the top of the lightning conductor.

THE CUTTER BRIDGE AT ELY.

IN pursuance of their policy of substituting wrought iron for cast iron bridges, the Great Eastern Railway Company, in the persons of Mr. John Wilson, their engineer, and Mr. Charles L. Morgan, the assistant engineer, superintended the removal on Sunday, November 24th, of the old bridge crossing the Ouse just to the north of Ely Station, and the erection of a new one in its place. The contractors engaged on the work were Messrs. Head, Wrightson and Co., Limited, and on their behalf Mr. William Anderson, one of the directors, and Mr. S. Young, the London manager, were present at the proceedings.

Ely is one of the busiest points of the Great Eastern system, inasmuch as there is, in addition to the passenger traffic between London and Norwich and the North, a still heavier goods traffic, which claimed serious consideration, and made it necessary that the work should be done in an absolute minimum of time possible. The original idea of engineers and contractors was to get the whole work through—that is to say, the work as regards taking out the old bridge and fixing in the new—within eight hours; but unexpected difficulties arose in connection with the removal of the old structure—as unexpected difficulties, indeed, have a habit of doing—and three more hours were required. All the same, as the traffic was conducted for some time on a single line, the period for which the passing of trains was rendered impossible was reduced to eight hours, and inasmuch as there were no trains at all due on the Sunday afteroon for half of that period, the actual obstruction of traffic amounted to only four hours. Considering the exceptional difficulties encountered, it was a remarkable performance, and highly creditable to everyone concerned.

The chief trouble consisted in the removal of the old bridge, which, built in 1845, was a nine-span timber-pile structure, three of which supported cast iron girders as superstructure, the remainder being timber, and offering any possible number of uncertainties in the way of bolts, fastenings, and so on, which might impede progress when everything appeared straightforward. Thus the matter was a much more serious one than the lifting out of one iron bridge and the putting in of another. The old structure had a total length over all of 220ft. in the nine spans, but six of these spans, and more than one-half of the total length, stood over the land on each side of the river, the open spaces there making provision alike for flood openings and for allowing local residents to pass from the fields on one side of the railway to those on the other. But these openings have now been closed up, and in their place are embankments terminating in brick abutments, on which the new bridge rests. Thus the new bridge is substantially shorter than the old one. It forms a single span of 75ft. on the square and 91ft. on the skew, with a length over all the girders of 101ft., the superstructure consisting of two main outside girders of wrought iron open lattice construction, 27in. 6in. apart from centre to centre, and 9ft. effective depth, resting on the brick abutments, and provided with expansion roller bearings with rocker and pin at one end. The rails are supported by cross girders 10ft. apart, centre to centre, with rail bearers, upon which the longitudinal timbers are bolted and the usual chaired road used. The net weight of the ironwork was 98 tons, but the timber and rails raised the total to 120 tons.

Such was the structure that was to be moved into position. It had been put together on temporary staging erected over the river, and alongside the older bridge, as near to it as the conditions of work would allow, and it stood ready, on trolleys and rails, for the final operation of traversing.

The uncertainties presented by the old timber bridge have already been mentioned, but there was a still further complication arising from the fact that the river crosses under the line at a very acute angle, so that the two powerful locomotive steam cranes employed—one raising ten tons and the other five tons—were of but little use for the removal of the down line of the old bridge when the up line had been taken away. Had the river been running at right angles with the railway matters would have been much simplified.

The time fixed for commencing the work of removing the old bridge was a quarter of an hour past midnight, but the last down mail train was late, and there were also important goods trains to be got rid of, so that it was after one when operations—facilitated by the use of Wells' lights—really began, though even then there were constant interruptions owing to the necessity of removing the locomotive cranes from the down line, which was to remain open until midday. From this line the cranes lifted, one by one, the six girders and their timbers, which formed the three remaining spans of the up line over the old bridge, the first of them being lifted and taken away within twenty minutes of the passing of the last train. Each girder was raised and carried off by the two cranes to a point lower down the line, where they were at once placed on wagons for removal. This part of the work went off quite easily, no difficulty presenting itself. The old girders having thus been got rid of, the crowns of the piles on which they had been placed were sawn through, where that process had not already been done, and these in their turn were carried off by the cranes, so as to allow the new bridge to be traversed into its proper position. The lower portions of the piles were left standing in the river bed for the time being. Everything was thus ready for the moving of the new bridge into the position which had been occupied by the up line, and as close as practicable to the still remaining down line, or about one-half of the total distance it would have to travel towards its final destination from that part of the temporary staging on which it had been constructed. To facilitate this operation the complete structure of the bridge stood on four trolleys, which in their turn were on rails along the heavy staging running parallel with the river.

The traversing was accomplished by means of two winches which stood on the bridge, and were supplied with ropes passing from them and under the bridge to some timbering on the other side to which they were attached. The distance which the bridge had to travel bodily on this occasion was 15ft., and the time occupied in the operation was altogether thirty-five minutes, great care having naturally to be taken to ensure that the two sides moved at the same rate. The trolleys worked admirably, and the operation went off without the slightest hitch, proving a complete success. This was the end of the morning's work, which, leaving out of account detentions amounting to at least an hour and a-half on account of the passing of goods trains, had occupied three and a-half hours, thus bringing the workers up to six o'clock in the morning.

Between this hour and midday the ordinary Sunday morning traffic, both up and down, was conducted over the down line of the old bridge, which had, so far, not been interfered with, and this was done with but little delay. At noon the contractors' men re-appeared on the scene of operations, hoping to be able to accomplish the feat of completing the work by about four o'clock, which would have left enough margin of time to do the permanent way connections before the next train was due. But the afternoon's work proved to be much more difficult than that of the morning. When the steam cranes stood on the down line of the old bridge it was a very easy matter for them to pull up the six girders of the up line, one after the other. But now there was only one line available, and as the cranes had not length of jib enough to lift the girders, in consequence of the acute angle of the bridge, an entirely different course had to be adopted. The idea was to first raise out of its bed on the piles, by means of hydraulic jacks, each of the two complete lengths of old girders, rails, and timbering stretching across the river to form the down line; and then to draw these complete lengths bodily, one after the other, with the help of winches, along a continuation of the temporary staging, so that they would not interfere with the complete traversing of the new bridge; the massive beams—which represented each a length of about 100ft. and a weight of 35 or 40 tons—being left on the staging to be dealt with on a future occasion. But the bridge-builders of forty-five years ago had done their work so well that it seemed at one time almost impossible to pull it to pieces, and it was not until three o'clock—that is to say, after the men had been at work for three hours—that this particular item in the programme was accomplished. The next thing was to get rid of the crowns of the piles, and as these immense blocks of timber, with their iron bed-plates on which the girders had rested, could not be reached by the cranes, they were unceremoniously tumbled into the river, where they disappeared with a tremendous splash, which was especially appreciated by the local residents assembled on the towing-path.

After this came the final stage in the traversing of the new bridge, so as to bring the rails with which it had already been provided in line with those on the permanent way on either side. This required only another half-hour, the massive structure gliding along the rails with a perfect smoothness. Thus the total time taken in moving along a distance of 30ft. the whole mass of the new bridge—complete as it was constructed, and weighing 120 tons—had been just one hour.

Now came the task of raising the bridge off the trolleys, so that these could be removed, and the bridge then be lowered into position on the bed-plates and abutments. The raising was accomplished by means of hydraulic jacks at each corner, and the expansion rolling bearings, with rocker and pin, having been fixed at one end, the bridge was finally lowered into position, and declared duly fixed, by a quarter to eight in the evening. In the meantime the platelayers had been putting down the rails to join those of the permanent way with those already fixed on the bridge, and the up line at least was perfect by eight o'clock, when the Norwich express—fortunately somewhat late—steamed slowly but safely across the new bridge on its way to London. Thus the actual working time spent in removing the old bridge and putting the new one in its place, available for the resumption of traffic, was only a little over eleven hours.

THE PROPOSED LONDON AND SOUTH WALES RAILWAY.

(*From a Correspondent.*)

THE abrupt abandonment of the projected railway from London through Oxford to South Wales has caused no little surprise and a good deal of disappointment in the district, where for two or three years past an agitation in favour of an independent line to the metropolis has been maintained by the whole mining industry and nearly every representative public body. It was not a case of withdrawing a tentative scheme, hastily prepared, in order that it might be formulated anew in a more complete manner for presentation to Parliament another year. Here surveys had been made, plans prepared, the Bill drafted and deposited, the first directors of the new company nominated, and actually a secretary appointed in the person of Mr. Connacher. All seemed to be going well, when suddenly came the announcement that the promoters, after a conference with the Great Western Railway directors, had determined not to proceed with the undertaking,

The promoters, as specified in the deposited Bill, were the directors and leading shareholders of the Barry Railway, and it was between their representatives and a committee of the Great Western directors that the conference took place. We reproduced last week some of the terms on which it is said that the understanding to abandon the Bill was arrived at; but it requires no special power of divination to discover that the conditions therein mentioned cannot exactly consist of *the* terms, or all the terms, on which the Barry Company consented to sacrifice its elaborate and long-maturing project. For example, the new line of the Great Western Company from Patchway to Wootton Bassett, which would leave Bristol to the south, and shorten the distance to London by twelve miles, was contemplated, as our columns will show, long before the London and South Wales Railway was definitely described in a Parliamentary notice. The extension and "opening" of Cardiff station, and the doubling of the road between that town and Newport, are works which have been proceeding for months past, and for which the money was voted a year ago.

The only concessions that appear to be new, and that are mentioned in the semi-official explanation of the Barry Company, ara a reduction of the coal rate to Southampton by 6d. per ton—undoubtedly a great boon to Welsh coalowners; a promise that very effort shall be made to reduce the rate for bunker coal to London, though on this point the Great Western at present finds its hands tied by agreements with other main lines; and an infinitesimal benefit to passengers by equalising the first and second-class fares between Paddington and South Wales with those charged on other portions of the Great Western system. These matters have long been the subject of discussion between the Great Western and the Chambers of Commerce and local authorities of the South Wales ports; and under the more liberal policy Lord Emlyn has introduced into the Great Western administration there was good reason to believe that the reforms would have been carried out in due course. There is, at all events, some justice in the complaint, raised alike in railway circles and in the industrial districts of South Wales, that if this is all that the Barry Railway has secured as its part of the bargain, it is not sufficient to justify the disturbance its scheme has caused to Great Western shareholders, whose property it threatened, or to the colliery and trading interests, whose hopes it had fired only to quench them in a douche bath of a disagreeably unexpected character.

It is quite intelligible that the coalowners and others—and probably not a few engineers as well—who placed their trust in the good faith of the promoters, should express an honest scepticism as to whether the items already mentioned represent the whole of the conditions on which the Bill was withdrawn, and whether they do not omit some very material advantages which the Barry Railway Company has secured for its system and its shareholders. In the nature of things a railway company does not usually play the part of philanthropist at large, and still less is it to be presumed that a character for universal benevolence would naturally attach itself to a young railway company which was established as an aggressive power, and owes its 10 per cent. prosperity to its legitimately enterprising aggressiveness. The two daily journals in Cardiff, which do not often agree in discussing Barry affairs, are for once of opinion that the Barry directors have been too modest in setting forth their own share of the benefits that are to accrue from the arrangement which has been made with the Great Western Company.

The Barry Railway, as everyone knows, has been making efforts to get access to the Monmouthshire coal valleys. That was the object of the East Glamorganshire Railway, which it twice unsuccessfully tried to carry through Parliament. That is the purpose of the proposal, in its present Bill, to construct a short line between its own railways to a junction with the Rhymney Railway at Walnut Tree Bridge. It is now stated that a part of the compromise with the Great Western Company is that Barry Dock is to be grouped with the Cardiff and Penarth Dock, in regard to the rates from Newport, for all coals brought down from the Monmouthshire coalfield, in which case Barry, with its lower dock dues, and more favourable position, would challenge the Newport trade and become a more formidable rival of Cardiff than it is to-day.

A more important statement in the *Western Mail* is that the withdrawal of the Bill was but one plank in a programme which includes the ultimate absorption of the Barry Railway and Dock in the Great Western system. It looks at first sight improbable, but it is not intrinsically so. The Great Western Company wants a dock in the centre of the Welsh coalfield. It has dock interests at Swansea, larger interests at Llanelly, and it is an open secret that the late Sir George Elliott did not despair of concluding negotiations whereby the Newport Alexandra Dock would have passed to the Great Western Company. The acquisition of the Barry Company's property would involve also that of the Barry adjunct or "feeder," the Vale of Glamorgan, and thus the Great Western Railway would gain a second route for its already congested mineral traffic between the coal valleys converging at Bridgend and the ports upon its main line.

CASTING PUMP PIPES.

THE following paper from the pen of a foreman moulder will be found instructive, we believe, by many of our readers. It describes Scotch foundry practice, which differs in some respects from that of English foundries:—

The writer in introducing this subject will endeavour, as far as possible, to do without the aid of drawings, and the sketches employed are not drawn to scale. At Fig. 1, in cross section form, is the box with the pattern rammed. As there is nothing of special importance in so far as the ramming up of a pump pipe is concerned, it would only be waste of time to dwell on this point, as the sketch should make itself sufficiently clear.

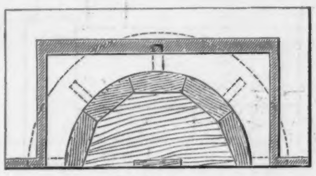

FIG. 1

Fig. 2, a longitudinal section, shows the core bar perforated with holes, to allow the gas which forms in casting to find its way of escape. The core is composed of straw rope and loam. To make a good core suitable in every way, about 2in. should be allowed for the thickness of the straw and loam. The first coat should have one course of straw rope about 1in. thick, rubbed up with black loam while revolving on the core tressels. In callipering, leave about ¾in. for the second coat, which is the finished size of the core, whatever that may be. The loams are generally known as black and red; to the writer's mind the terms are misnomers. He prefers to call them first and second coat loam. The first may be made of any old black sand, providing it is given sufficient plasticity through the addition of the requisite amount of earthy clay. It matters little though the core should be cracked, so long as the loam keeps firm to the straw ropes. Second coat loam is made from river sand. This sand has generally sufficient cohesiveness and porousness, If it is wanting in either it is easily toned by adding clay to bring up the required cohesion. On the other hand, should it have an over abundance of clay, it can be reduced to a proper consistency by the addition of sea sand. Some foundries through force of circumstances are compelled to use sea sand, with clay added, for this sort of loam. This must be a disadvantage, as sea sand has none of the properties that go to make a good loam; in consequence of it being small in grain it is bad for venting, and likewise it is altogether free of plasticity, which is an absolute necessity in second coat loam. If the core after being coated and dried, when taken from the stove should show itself too severely cracked and somewhat glazed on the surface, it may be regarded as a doubtful core.

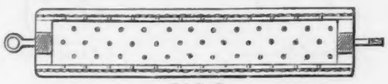

FIG. 2

To avoid possible blistering of the casting, all apparent glaze should be removed by carding before blackwashing. The cracks and hard glaze are the result of too much clay in the loam; that being so, it is easily rectified by a judicious application of sea sand. Any other substitute entirely free from plastic matter, such as sawdust, will also improve its porousness for venting. Finishing and drying the mould may be passed by, as the knowledge how to do it can only be acquired through long and continued practice. The longitudinal section—Fig. 3—shows everything in position previous to casting. In this section is seen the mould finished, cored, closed, and ready for casting. The sand of which the mould is composed is known as rock sand, a rotten sandstone unsuitable for builders. The more rotten it is the better suited it is for moulding purposes. It must have porousness for easy venting, combined with cohesiveness to keep it well in form, to enable it to make a sufficiently strong mould. A, Fig. 3, shows the flow gates.

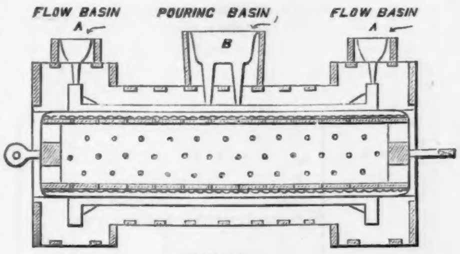

FIG 3

The flow gates are employed for the specific purpose of brightening up the flanges. Without their use the impurities floating on the surface of the metal would find their way to this, the highest part of the mould, and, along with the dullest of the metal, which is always in front, would thus spoil the casting. B, in Fig. 3, shows the pouring gate with its basin. It is necessary that the basin should be sufficiently large to enable all scum which may be floating on the metal still to keep floating in the basin. It is for want of this provision being made that many good moulds are lost, through the metal dropping direct from the ladle to the mould. This is a most important matter in every form of casting. Having thus far shown the various stages in moulding a pump pipe, the writer will next show the three positions of casting, and give their consequent results—(1) Horizontal position; (2) "on the bank," or, as may be more technically put, at 45 deg.; (3) the vertical position. (1) Fig. 4, showing the horizontal position with gates on the top side of the casting, will assist in conveying to the reader how oxide is formed and destroyed, as is also shown in cross section at Fig. 5. The reader must fancy the molten metal striking the top side of the core and finding its way rapidly to the bottom. The moment it reaches the bottom of the mould oxide begins to form, and increases in quantity until the mould is half filled. In cross section at arrows 1 and 2 will likewise be observed the molten metal, shown in bulby form. This is the form it takes when its surface is heavily laden with oxide.

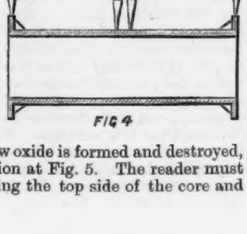

FIG 4

From this point it must be apparent, as the metal with its oxide rises to arrow No. 3, it is seized by the hot metal coming from the pouring gates, which destroys all oxide and passes into combination with all other impurities akin to cast iron. This running of the mould from the highest part of the body in a great measure removes the danger of blistering and cold shot, which is common to horizontal pipe casting. (2) Fig. 6, "on the bank," or at the angle of 45 deg. position, may be said to be *the* position for casting pump pipes. The arrow shown in sketch, with the aid of the bulb as representing oxide of iron, shows the most defective part when cast in this position. This oxide, which is the parent stage of cold shot, is formed through the long run the metal has from its entering the basin, passing down through the gates, then running to the extreme bottom of the mould, and rising up over the back of core, as shown by the arrow. Should the metal when casting be of a pale cherry red, and not milky-white colour, oxide is greatly intensified. Be it observed, this the bottom end is the most defective part, notwithstanding its greater compression when casting; and the only way to avert this possible danger is to cast at a milky-white heat, though it should be at the expense of a rough casting, for if once this oxide bulb be formed, there is no compression capable of destroying it. This oxide bulb is commonly called cold shot. Cold shot may be said to be analogous to a knot in wood, the surface appearing sound and perfect, and the defective part or parts only revealing themselves when under pressure of steam or water.

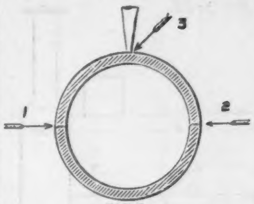

FIG 5

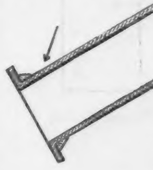

FIG. 6.

Fig. 7 at top end, flaked and dotted, shows the only defective part or parts possible when a pipe is cast on end. In this position there are no such defects as cold shot, blistering, or unequal thicknesses possible, providing ordinary care be exercised by the moulder. The defects as shown in Fig. 7 are caused through the molten metal having such a lengthy drop to the bottom of mould. It is almost impossible for it to strike the bottom without creating more or less dust, should nothing worse happen. This dust accumulates when the mould is in the act of filling, and along with what oxide it gathers can only produce results as shown in sketch. Were one to analyse the contents of the top end of the casting it could only prove to be metal of a very doubtful character. Again, there are other troubles to contend with in this position, viz., vacuum holes created through "draw," "setting down," or solidification. These all concentrate themselves in the top end. Thus it will be seen, although this position is highly favoured in many points, the good is more than counterbalanced in the other ways enumerated. Therefore, unless it be to secure a proper "bore," such as is necessary in a working barrel or cylinder, vertical casting is not commendable. In short, were this a casting 15ft. to 20ft. long, it would take no small amount of trimming before satisfaction could be attained under a hydraulic test. To show how in a great measure one can obviate the ills that accompany vertical casting, the writer gives, Fig. 8, the arrow 1 pointing to a dead head, to be subsequently cut off. There is a provision made in the mould to receive the impurities that are floating on the metal while the mould is in the act of filling. But this dead head is not always satisfactory. If we can imagine the metal rising up past the flange at the arrow 2, it will be seen how impurities on the surface are partially trapped, and in consequence never reach the sinking head at all, the casting showing an imperfect face when the sinking head is cut off. The best part of it will be right round the core, that part having an uninterrupted rise to the highest part of the mould.

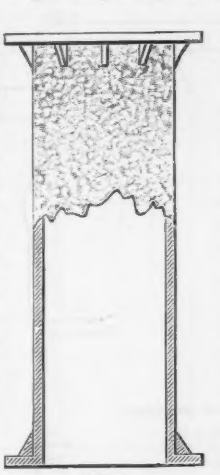

FIG. 7.

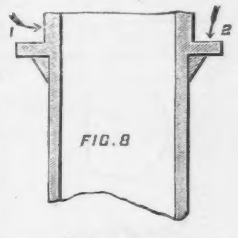

FIG. 8

Regarding the length of the sinking head, the longer the better; but if it be the first part of the casting to "set down," or solidify, it is entirely useless. The point to observe is to make it so heavy that it will be the last part to set, as it is from this reserve the natural demands of the casting are supplied, viz., feeding to solidify the entire casting during the process of cooling.

THE SUNFISH TRIALS.—The average of three hours trials of the torpedo boat Sunfish recently gave 27·581 knots per hour. The mean speed for six runs over the measured mile on the Maplin was 28·082 knots. Going with wind and tide, she performed knot after knot under two minutes. The mean steam pressure in the boilers was 188 lb. per square inch, and the mean revolutions were 351·2 per minute. The average indicated horse-power developed by the engines during the trials was 4174.

OLD GREAT SOUTHERN AND WESTERN RAILWAY LOCOMOTIVES.

In our last impression we illustrated one of the passenger locomotives supplied about 1847 by Messrs. Bury, Curtis, and Kennedy, to the Great Southern and Western Railway of Ireland.

Through the kindness of Mr. Ivatt we now give a number of diagrams supplying the leading particulars of the early locomotives on that line. It will be seen that there was no standard. For the most part the line is level; the only really heavy bank on it being that from the Kingsbridge terminus in Dublin to Inchicore. The conditions are wonderfully like those of the London and North-Western between Euston and Chalk Farm. In the early days tickets were collected at Inchicore, and then the engine was detached, the train running down to the terminus by gravity. We are unable to add any information to the diagrams. There is no date on the chart, but it is probably 32 years old, and the ink has in many places faded. The Great Southern and Western Railway was, from the beginning, a first-class line, and no expense was spared in its construction. The permanent way was far heavier than that of any other line in the world; indeed, 90 lb. rails are not too common now. The sleepers were of excellent quality and abundant, those under the joints were 18in. to 24in. wide; in many cases slabs of beech; the flanged rails were secured by hooked spikes. But for lack of money the renewals and repairs were few, and twenty years ago the line was, perhaps, the worst in the world. The iron rails had become crystalline, and broke with great ease. On the branches lengths of six or seven feet, and not infrequently lengths of but three feet were abundant. But the reconstruction of the permanent way has been energetically carried on, steel rails in chairs have been laid, and now the main line is excellent, and little fault is to be found with the branches. No doubt the bad condition of the rails was very trying to the locomotives, and the performance mentioned in our last impression bears the fuller testimony to the excellence of the engines made by Messrs. Bury, Curtis, and Kennedy.

THE EFFECT OF STRIKES IN THE UNITED STATES.

A recently issued report by Mr. C. D. Wright, Commissioner of Labour, upon the strikes and lockouts of the past seven and a-half years, shows that the employers have lost 29,000,000 dols. and the men 35,000,000 dols. During this period the State of Illinois had the largest number of establishments affected, both by strikes and lockouts, there having been 10,060 of the former and 1193 of the latter. New York came second on the list, with 9540 establishments involved in strikes and 723 in lockouts, and Pennsylvania third, with 8219 strikes and 490 lockouts.

The industries most affected by strikes were the building trades, with 20,785 establishments involved; coal and coke, with 5958; clothing, with 3041; tobacco, with 2506; food preparations, with 2398; stone quarries and cutting, with 1993; metals and metallic goods, with 1834; transportation, with 1327; printing and publishing, with 608; boots and shoes, with 607; furniture, with 459; wooden goods, with 409;

and brick, with 406 establishments. Those most affected by lockouts were the building trades, with 1900; stone quarrying and cutting, with 489; clothing, with 431; brewing, with 150; boots and shoes, with 130; metals and metallic goods, with 128; and transportation, with 112 establishments involved. The total number of employés involved or thrown out of employment during the period covered by the report was 2,391,203.

The States in which the majority of the strikes and lockouts were located were five in number, and were respectively Illinois, Massachusetts, New York, Ohio, and Pennsylvania. The strikes in this quintet of commonwealths were about 70 per cent. of the whole number of establishments in the United States affected by strikes, while the lockouts were about 76 per cent. of all those throughout the country. The report shows that these five States contained 51 per cent. of all the manufacturing establishments, and employed 56 per cent. of the capital invested in the mechanical industries of the country, taking the census of 1890 as the basis of computation.

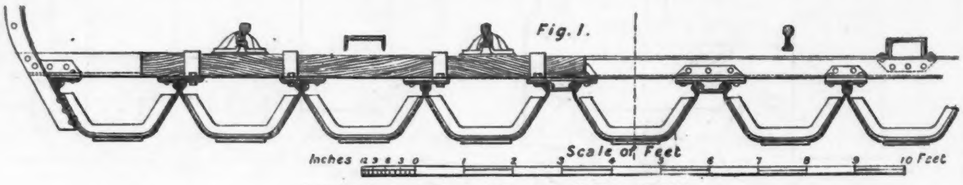
In New York City the wage loss of employés was nearly 6,500,000 dols., exclusive of 792,000 dols. contributed to them by other labour organisations, while the loss of employers was a little more than 3,500,000 dols. The number of strikes in Boston was 257, with a loss to the employés of 800,000dols., as agains 589,000 dols. for the employers. The total number of strikes in Allegheny and Pittsburg was 251, but the loss of wages was 7,379,765 dols., while the loss to employers was 2,600,000 dols. In Chicago, where the strikes aggregated 528, the loss to employés reached nearly 9,000,000 dols., while that of the employers was nearly 14,500,000 dols. In Paterson, N.J., where the number of strikes was only 47, the loss to employés was more than 1,000,000 dols., as against half that sum for the employers. The total wage loss to the employés in twenty-six leading manufacturing cities was in round numbers 35,000,000 dols., while the loss to employers was something less than 29,000,000 dols.

The number of lockouts as compared with the strikes for the same period was small in the aggregate, but the losses incurred were enormously increased. The total was 244 lockouts, with a loss of wages to the employés of 12,000,000 dols., while the loss of employers was nearly half that sum.

For the period covered by the report, out of the 46,863 establishments affected by strikes, success in their demands was gained by the employés in 20,397; partial success was gained in 4775 establishments, and failure followed in 21,687 establishments. Out of the 3853 establishments having lockouts, 1883 succeeded in gaining their demands; 391 partially succeeded, and 1558 failed. The leading cause of strikes was for an increase of wages, and these represent 25 per cent. of the whole number. 13 per cent. were for reduction of hours; 8 per cent. were against reduction of wages; 7 per cent. were sympathetic; 6 per cent. were for increase of wages and reduction of hours; 4 per cent. were against employment of non-union men, and 3 per cent. for a recognition of the union. The remainder of the strikes are attributed to a number of other causes of no especial general interest.

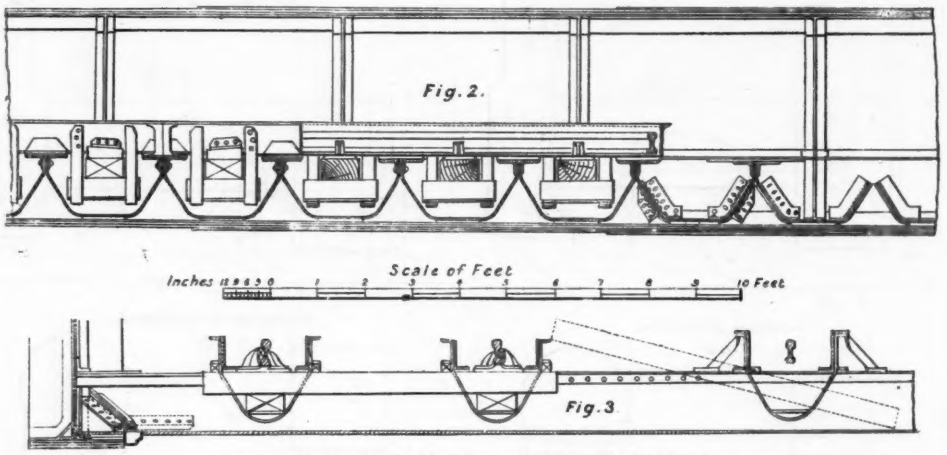
BARKER'S BRIDGE FLOORING.

RAILWAY engineers in this country have employed various corrugated floorings in their bridge work for a number of years. So far back as 26th October, 1865—thirty years ago—the late Mr. Thomas Russell Crampton applied for a patent for corrugated floorings, built up of sections of convenient size, stamped, pressed, or rolled from plates. Since that time quite a number of "improvements" have been devised, and corrugated floorings are often now used in bridge work where cross girders with flat or buckled floor plates used to be the rule. Corrugated floorings are also undoubtedly making headway in the United States. They are in use on the Illinois Central Railroad, the Lake Shore and Rock Island Elevated Railway, and elsewhere. They are also to be employed in the construction of the New York Central four-track viaduct over the Harlem River.

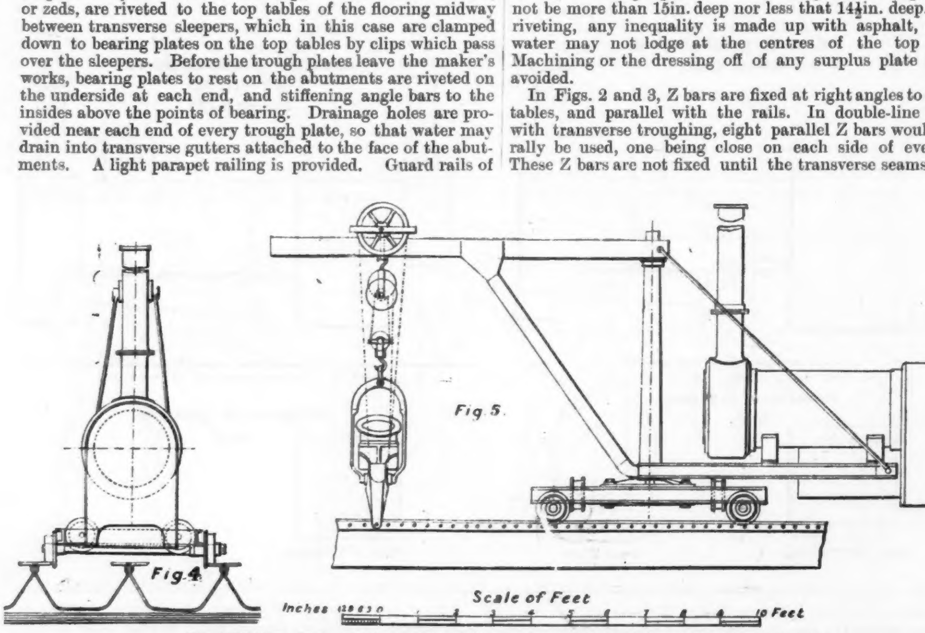


BARKER'S BRIDGE FLOOR FOR SHORT SPANS

We recently illustrated a number of the most used forms of bridge floor—THE ENGINEER, 18th and 25th October, 1895—and we now illustrate a new steel flooring which has been brought to our notice by Mr. Gerald Barker, of 1, Victoria-street, Westminster. It will be seen to possess novel features, although, in common with other systems, it is largely composed of bent plates, which in this case form troughs. The trough plates are placed side by side. A stiff angle bar is attached to each side of the ridge formed by the abutting sides of adjacent trough plates. Fig. 1 shows these plates laid longitudinally in the case of short spans. Transverse Z irons, or zeds, are riveted to the top tables of the flooring midway between transverse sleepers, which in this case are clamped down to bearing plates on the top tables by clips which pass over the sleepers. Before the trough plates leave the maker's works, bearing plates to rest on the abutments are riveted on the underside at each end, and stiffening angle bars to the insides above the points of bearing. Drainage holes are provided near each end of every trough plate, so that water may drain into transverse gutters attached to the face of the abutments. A light parapet railing is provided. Guard rails of inverted channel section are riveted to the transverse zed irons in the centre of each four-foot way.

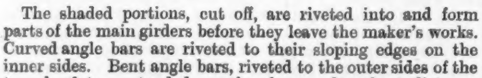


BARKER'S BRIDGE FLOORS WITH TRANSVERSE TROUGHS



DE BERGUE AND CO.'S STEAM RIVETTING PLANT FOR BARKER'S FLOORS

Figs. 2 and 3 show a plate girder bridge in longitudinal and transverse sections. In this case the trough plates are laid transversely, and the ends of the trough plates are cut on a slope, thus—



The shaded portions, cut off, are riveted into and form parts of the main girders before they leave the maker's works. Curved angle bars are riveted to their sloping edges on the inner sides. Bent angle bars, riveted to the outer sides of the trough plates, extend down the slope and a short distance along the sides of the trough plates near the bottom. Short lengths of flat bar are fixed across the cut sloping ends of the trough plates, and riveted to the outside bent angle bars before erection. The width of these flat bars is equal to the width of the outside angles + the thickness of the trough plate + the width of the inside angles. When the trough plates are in position the inner halves of these flat bars become interposed between the curved angle bars on the insides of the trough plates and those on the insides of the short lengths of trough plate which had previously been riveted to the main girders. The rivets to be put in after erection pass through the inside angles of trough plates, the flat bars, and the angles riveted to short lengths of trough plate. A riveting machine with a very small gap can do this work, and all riveting through main girder webs at the site is avoided.

The pairs of angle bars which form the top tables of the flooring extend from web to web of main girders. Horizontal gusset plates may be used, as shown, to connect the top tables of the flooring to angle bars, which run between the stiffeners of the main girder webs. The web stiffeners on each side of the main girders extend from flange to flange. Longitudinal guttering is attached to the inside edge of the bottom flange of each main girder. Both long and short lengths of trough plate drain into these gutters. Down spouts are provided at the four corners of the bridge.

It will be noticed that the edges of all the trough plates are shown to fall short of the level of the top tables of the flooring, the reason being that half an inch allowance is here made for inequalities in the edges of the plates. In other words, the trough plates for a flooring of 15in. depth must not be more than 15in. deep nor less that 14½in. deep. After riveting, any inequality is made up with asphalt, so that water may not lodge at the centres of the top tables. Machining or the dressing off of any surplus plate is thus avoided.

In Figs. 2 and 3, Z bars are fixed at right angles to the top tables, and parallel with the rails. In double-line bridges with transverse troughing, eight parallel Z bars would generally be used, one being close on each side of every rail. These Z bars are not fixed until the transverse seams of the flooring have been riveted. The Z bars are then laid level, or parallel to the gradient of the railway. Packing plates, about 11in. by 7in., and of varying thickness, are inserted between the undersides of the Z bars and the top tables of the flooring. When a bridge is temporarily erected in the maker's works, these packings may then be adjusted and attached to the Z bars by a couple of extra rivets, countersunk on the underside. This would reduce the number of loose parts to be conveyed to the site, and would save considerable time in erection. These eight Z bars give great lateral support to the top tables, and divide their lengths into nine bays, the longest of which is about 4ft.

In all cases cross sleepers may be used with this flooring. In Figs. 2 and 3 they are supported on longitudinal timber packings of the same scantling as the sleepers—10in. by 5in.—and about 1ft. 9in. long. These packings rest on either wrought or cast iron bearing plates suspended in a pair of transverse loops or stirrups composed of flat or angle bars. The ends of these loops or stirrups are riveted to the webs of the pairs of longitudinal Z bars. As the stirrups are short a large factor of safety may be allowed without extravagance. The rivets are merely subjected to shearing stress, and there are no sharp bends in the stirrup loops. The sleepers are shown to be held down on their respective packings by hard wood keys or wedges driven between the tops of the sleepers, and inclined angle iron chubs riveted to the webs of the longitudinal Z bars. The use of bolts is thus avoided, but, of course, there are other methods of securing the sleepers. Junctions, crossings, and turn-outs are not often met with on bridges; but where they do occur special arrangements of Z bars and sleepers are provided.

This form of flooring is not limited in its application to plate girders or lattice girders of multiple triangulation. The trough plates are not cut obliquely, as in Figs. 2 and 3, but are each in one piece, from girder to girder. The horizontal rivets through end angles of trough plates and sides of main girder booms have only shearing stress to resist all pull upon them, through deflection of the flooring, being obviated by horizontal ties across the main girder booms. These ties extend some little distance along the top tables of the flooring. Diaphragm plates, about 5ft. apart, are fixed in the girder booms; or, with a slight alteration in the web members, short lengths of trough plate may be fixed in the booms with short top table angles attached. Cover strips may then be used at every top table. The material required for this flooring consists of ordinary trade sections, and the plates are of dimensions easily obtained and bent to the required shape. The rest is merely a matter of drilling or punching, and riveting. All parts are made interchangeable.

The heaviest pieces of this flooring weigh about 15 cwt. each, and as there are plenty of holes along the upper edges of the troughs, there should be no difficulty in attaching lifting tackle. The trough plates only require to be "landed" in position; no "threading-in" is needed, and being somewhat of wedge shape, the last plate makes a place for itself. The pairs of angle bars which form the top tables of the floor may be fixed after all the trough plates are in position, or may be attached concurrently with the fixing of the plates. The riveting of the seams immediately under the top tables is then proceeded with.

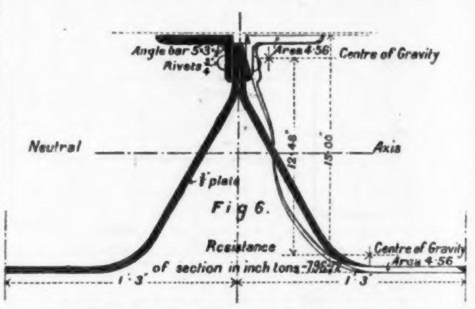


DIAGRAM OF STRESSES IN FLOOR TROUGHS

The whole of the operations of erecting and riveting can be carried out without any scaffolding alongside or underneath the bridge. There is, therefore, no possibility of timber, tools, or rivets falling below. This is undoubtedly an advantage when a bridge is being constructed over traffic of any kind. Men engaged on the work are also saved considerable risk of accident. Every rivet can be put in by machine, a portion at the maker's works, the remainder after erection. Machine riveting is decidedly preferable to handwork. No better proof of this can be given than when hand and machine rivets require to be cut out. When the head has been cut off the former, it can generally be driven out, but it is often necessary to drill out the machine rivet, as it completely fills every irregularity in the holes.

Figs. 4 and 5 illustrate a portable steam riveting plant specially designed by Messrs. De Bergue and Co., Limited, of Manchester, for the riveting of this flooring. It will be seen to consist of a rolling carriage traversing the top tables of the flooring. A small jib crane swivels on a centre standard bolted to this carriage. One of Allen's patent riveting machines is suspended from a roller which can be run in or out along the horizontal jib by means of an endless chain. A horizontal boiler, working at a pressure of 70 lb. per square inch, is carried at the tail end of the crane. The riveter may be either of horseshoe or clipper type. These machines are so generally used by bridge builders in conjunction with an air compressor and receiver, that we need not describe them in detail. Illustrations of Messrs. De Bergue's portable pneumatic plant appeared in THE ENGINEER, vol. lxxv., pages 71, 73, and 75. In this case, however, steam is conveyed from the boiler to the valve chest of the riveting machine by flexible hose.

Messrs. De Bergue's steam riveting plant dispenses with the air compressor and receiver of their pneumatic plant, or the pumps and accumulator of portable hydraulic riveting plant. While the riveter is working, steam must be kept up to ensure uniform quality of work. A 10in. cylinder is sufficient for 1in. rivets. A rivet-heating furnace can also be provided on the rolling carriage. A second set of wheels is fitted at right angles to the other set, and at a higher level. When the machine has riveted the seams within its reach, the carriage is jacked up, a pair of rails laid across the top tables of the flooring, and the crane carriage conveying the complete riveting plant runs on the second set of wheels to the next lot of seams which require its attention, and is there lowered once more on to the top tables.

The trough plates may be closely and firmly clamped together over the whole of their abutting surfaces, if machine riveting is employed. The friction between surfaces so clamped together is undoubtedly of great value.

No ballast is used with this flooring. Ballast on an iron floor is objectionable, as it produces oxidation and shortens the life of a floor. It also adds to the weight of a bridge, and increases the cost of flooring and main girders. Mr. Barker's flooring is designed to be water-tight. It will be observed that water falling upon it drains to gutters below each end of every trough, which are so placed that they prevent water reaching the connection of the flooring to the main girders, which is often a very leaky place.

In Fig. 1 each cross sleeper equally divides its load between four top tables, and brings four complete sections of the flooring into action. In Figs. 2 and 3 it will be seen that—without making any allowance for the distributive qualities of the longitudinal zeds, to which the live load and the weight of the permanent way are applied before reaching the top tables—the load on any sleeper is equally divided between eight points on the two adjacent top tables. But the longitudinal zeds do undoubtedly carry portions of the loading to the top tables 3ft. 9in. distant from the centre of the sleeper, and even to the tables beyond, with but slight deflection in the troughing. It is generally admitted that a shallow floor distributes the loading better than a deep floor, but that the deep floor is stiffer. Excessive deflections tend to loosen the riveted connections.

In determining the proportions of a corrugated flooring, it is generally assumed that the load on a pair of wheels of a locomotive is spread over a length of about 7ft. of railway. Now it is claimed that in the flooring under notice the four longitudinal zeds—8in. deep—to each line of rails distribute the concentrated sleeper load almost equally over sixteen points on four top tables, and with very slight deflection call upon four complete sections to sustain that load.

If we take 18 tons as the maximum sleeper load, and 90in. as the distance from bearing on main girder to centre of gravity of the two driving wheels of the engine, we get a bending moment, $M = 18 \times 90 = 1620$ inch-tons. In Fig. 6, the effective area of a single section of Barker's flooring is graphically shown by the white spaces on the right-hand side of the section. The effective area of the complete section is 9·12 square inches, the effective depth is 12·48in. Taking 7 tons per sq. in. as safe working stress, we have the resistance of this flooring, $R = A \times D \times 7 = 9{\cdot}12 \times 12{\cdot}48 \times 7 = 796{\cdot}72$ inch-tons. The gross depth of this flooring, as shown in these drawings, is 15in. Its weight, including everything except rails, sleepers and fastenings, is 55 lb. per square foot covered.

If we leave the safe working stress out of the question, we have a moment of resistance in this flooring of $A \times D = 9{\cdot}12 \times 12{\cdot}48 = 113{\cdot}8$. If we assume that the sleeper load of 18 tons is only divided over two sections of this flooring, and that the longitudinal zeds have no distributive powers whatever, then we have a bending moment of $\frac{1620}{2}$ on each section. The maximum stress on the flooring would, even under these conditions, only amount to $\frac{810}{113{\cdot}8} = 7{\cdot}1$ tons per square inch of section. If three sections equally share the load, the stress is 4·7 tons per square inch.

As it appears, however, with slight deflection, that four sections will share the load, there seems to be no question as to the strength of this flooring. The zeds give great lateral support to the top tables, and enable them to resist heavy compressive stress. By reason of these distributing girders the seams are not liable to have their rivets loosened by deflection waves in the floor. Excessive local deflection cannot occur.

Every portion of this flooring is accessible for inspection and painting. With this flooring the ordinary rails, sleepers, and fastenings are used as on other portions of the railway. Any sleeper may be readily removed, without interrupting the traffic, by first packing up the rails from adjacent top tables and drawing the four wedges. The sleeper is then drawn a couple of feet towards the main girder. The packing in the pair of stirrups next six-foot way is removed, and the sleeper drawn back towards the six-foot way and bodily removed, as shown in dotted outline—Fig. 3. On single-line bridges the sleeper ends are cut thus,

to allow of their being drawn out in the four-foot way. No timber comes in contact with the trough flooring. In some iron bridges plates and bars have been seriously corroded and eaten away by contact with wood containing acids.

When the trough plates are laid transversely between main girders, as in Figs. 2 and 3, there is a vertical depth of 10in. of timber between the undersides of the chairs and the tops of the bearing plates in the stirrups. This should afford a good cushion between the rails and the steel work of the bridge. In these cases also the depth from top of rail to underside of floor is less than 2ft. in double-line bridges without centre girders. The top of rail is about 7½in. above floor surface. In Fig. 1 there is a practically continuous floor for a derailed locomotive to run on, the gaps between sleepers and transverse zeds being only about 8in. The tops of the sleepers may with advantage be kept a little above the zeds, as wheel flanges would cut into the former. The inverted channel guard rail is provided to keep derailed vehicles within the width of the sleeper track. When the troughing is laid transversely, as in Figs. 2 and 3, an even more continuous floor is provided, there being only 4½in. gaps between sleepers and top tables. The longitudinal zeds form efficient "guard baulks" on each side of every rail. These zeds also acting as distance pieces between top tables, check vibration and lessen the humming noise noticeable in some curved plate floors.

In conclusion, we would just point out that longitudinal timber sleepers or "way beams" are very troublesome either on flat plate or corrugated floorings, as, by reason of the longitudinal camber in the main girders, and the transverse camber in the flooring—to say nothing of local inaccuracies, cover strips and rivet heads—they have to be adzed and fitted to the ironwork. They conceal a considerable portion of the surface and render it inaccessible for inspection and painting. As the sleepers usually "break-joint" with the rails, it is necessary to take out two rails before one sleeper can be removed. Longitudinal sleepers afford little protection to a floor in case of derailment, but, on the other hand, increase the risk by raising the rail further above floor level.

As already mentioned, cross sleepers may be used with the flooring described. When the longitudinal zeds have once been fixed level or parallel to the gradient, the cross sleepers require no adjustment, as all the stirrup loops are of one depth. Cross sleepers afford considerable protection to a trough flooring, as they assist in receiving and bearing the brunt of the shock in the case of a derailed locomotive, carriage, or truck.

THE total approximate cost of the work executed in connection with the construction of the Blackwall Tunnel up to the end of December last is £573,560, of which £10,096 represents the value of the work done on the raised approach road. The cost of the operations during the past year was £106,703. On the south side of the river the cut and cover work was completed; and on the north side, out of a total length of 436ft., 398ft. had been executed. The caissons—see THE ENGINEER of 27th December last—for all the shafts are now sunk to their final level.

A NEW INTEGRATOR.

By A. RUSSELL, M.A., and H. H. P. POWLES, A.M.I.C.E.

MANY ingenious and practical forms of integrators have been devised,* but any integrator other than Amsler's is seldom met with outside the laboratory of a technical college, although Coffin's averager, as made by the Globe Engineering Company, Manchester, for indicator diagram work, is a good deal used. The great obstacle to their more general employment is their initial cost, an investment, by the way, that is very often justified, as Amsler's planimeter can be applied to perform almost any integration if we make some necessary graphical constructions first, which are in general very simple. In working out several forms of integrators depending on various mechanical considerations, we were forcibly impressed that nearly all of them to be really useful must be very well made, and therefore very costly. The beautiful simplicity and finished workmanship shown even in a cheap planimeter sets a very high standard for makers of integrating machines. The following integrator, however, is not only an exceedingly accurate instrument, but requires no special skill to construct. If an Amsler's planimeter is available, so that the rolling wheel and gear can be temporarily joined on to the simple wooden framework, then the necessary expense is only a few pence.

The object of the instrument is to measure for a point o $\Sigma\, r\, d\, \phi$, where r is the distance of o from a point on a curve, and ϕ is the angle r makes with a fixed line. All that is necessary, therefore, is to have a wheel rolling on the paper with its axis making a constant angle with r, and its distance from the fixed point always in a constant ratio to r. The length moved round by a point on the circumference of the wheel will then be proportional to $\Sigma\, r\, d\, \phi$.

The instrument shown in Fig. 1, taken from a photograph, is made of parallel pieces of wood, the joint pins being ordinary screws. The centre bar from A to C is double, and the pointer B is carried on a block of wood which slides between the two pieces forming the centre bar. At A the wheel from an Amsler's planimeter is connected by pushing it on to a square piece of wood fixed between the two sides of the centre bar. The anchor point C is fitted to a block of wood which slides freely between the two sides of the centre bar. The sliding blocks to which B and C are attached move quite freely between the bars, and simply keep the axle of the rotating wheel always in the same straight line with the points B and C. The whole arrangement of links and bars can easily be made by anyone who can use ordinary carpenters' tools.

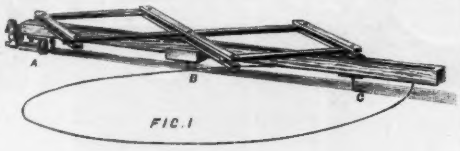

FIG. 1

The best way to calibrate the instrument is to move the pointer round a semicircle of radius r. Suppose the difference between the two readings of the wheel to be A, then the constant of the instrument is $\frac{\pi\, r}{A} = k$. Hence, if we move the pointer over a portion of a curve, and the difference between the readings on the wheel be A^1, then for that portion of the curve $\Sigma\, r\, d\, \phi = k\, A^1$.

The following are a few of the uses to which we have applied this form of integrator, and we have found that errors made in solving problems in this way are generally due to defective drawing, an error of one in a thousand due to reading the instrument being a rare occurrence.

(1) To calculate the elliptic integral, $\int_o^\phi \left\{ 1 - k^2 \sin^2 \theta \right\}^{\frac{1}{2}} d\, \theta$.

With centre A, Fig. 2, and radius A B = R describe a circle B C E. Make A O = k R, and make the angle B O C = ϕ. Let L be the reading of the instrument when the anchor is placed at O and the pointer is moved over B C. Then it is very easy to show that—

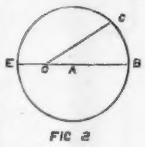

FIG 2

$$\int_o^\phi \left\{ 1 - k^2 \sin^2 \theta \right\}^{\frac{1}{2}} d\, \theta = \frac{L - a \sin \phi}{R}.$$

This integral, which represents the length of the arc of an ellipse, is denoted by E (k, ϕ); k being called the modulus and ϕ the amplitude. It occurs in problems in dynamics, and in many electrical problems.

(2) To calculate the elliptic integral F (k, ϕ)

$$\int_o^\phi \frac{d\, \theta}{\sqrt{1 - k^2 \sin^2 \theta}} = F\, (k, \phi).$$

Describe by any of the ordinary methods an ellipse whose excentricity is k.

Then, Fig. 3, O B being the semi-minor axis, make the angle P O B = ϕ.

Placing the anchor at O, move the pointer over the arc B P, and let the reading of the instrument be L, then

$$F\, (k, \phi) = \frac{L}{O\, B}.$$

This very important integral occurs in the formula for the time of swing of a simple pendulum and in the solution of many other problems in applied mathematics.

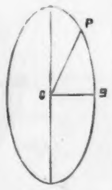

FIG 3

(3) To calculate the magnetic force at any point due to an electric current:

Let A B be the wire, Fig. 4, and let there be A ampères flowing in it, and suppose we wish to find the magnetic force at a point O due to this current.

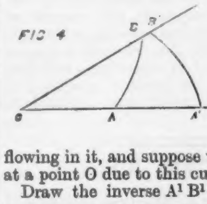

FIG 4

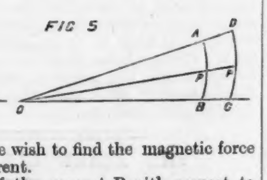

FIG 5

Draw the inverse $A^1\, B^1$ of the curve A B with respect to the point O by means of a Peaucellier linkage or otherwise.

$$\text{Then the magnetic force at O} = \frac{A}{10} \int \frac{d\, \theta}{r} \text{ C. G. S. units.}$$

$$= \frac{A}{10\, k^2} \int r^1\, d\, \theta \quad ,,$$

$$= \frac{A\, L}{10\, k^2} \quad ,,$$

Where L is the reading of the integrator when O is the fixed point, and the pointer is moved over, $A^1\, B^1$ and k^2 is the constant of inversion.

This integrator can also be used for solving many other problems, but the type of problem illustrated is the one which it solves most readily and accurately. One of us formerly used Amsler's planimeter to find $\Sigma\, r\, d\, \phi$ in the following manner:

Let A B be the curve, Fig. 5, and O the pole. Produce O P to p and make P p = k. Construct C D, the curve locus of p, so that A D = P p = B C = k.

Then since

$$\tfrac{1}{2} \int_o^\phi (r + k)^2\, d\, \theta - \tfrac{1}{2} \int_o^\phi r^2\, d\, \theta = k \int_o^\phi r\, d\, \theta + \frac{k^2\, \phi}{2}$$

$$\therefore \quad \int_o^\phi r\, d\, \theta = \frac{\text{area A B C D} - \frac{1}{2} k^2\, \phi}{k}.$$

Hence, the planimeter can be applied to find this integral, and therefore can solve the preceding problems. It is obvious, however, that for accuracy and rapidity an instrument of the form we have described is far preferable.

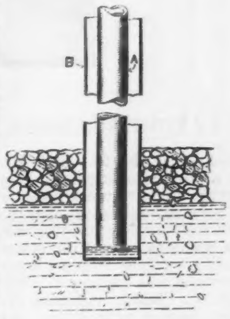
RAISING WATER BY AN AIR PUMP.

IN reporting upon an exhibition in the States, the American *Engineer and Railway Journal* of December says:—"There is one exhibit illustrating the increasing range in the use of compressed air that is made in connection with the Bacon system of increasing the flow of artesian wells by the Knowles Steam Pump Works. The apparatus on the ground is pumping water from a cistern 50ft. below the level of the floor. An air compressor supplies air at a pressure of 10 lb. per square inch, and the delivery is 250 gallons per minute. With a pressure of 35 lb. per square inch, 100 gallons per minute can be raised from a well 250ft. deep. The water is literally blown up, and in order to explain the operation we refer the reader to the accompanying diagram. A is the water pipe, and outside it the casing B is sunk so that the lower end of the latter is a trifle below that of the former. In the water-bearing strata the water level is supposed to stand at C, and it will have a constant tendency to rise about the bottoms of the pipes and enter them. The compressed air that is forced down between the casing and the water pipe drives the water before it, and, as it turns at the bottom to enter the inner pipe, it catches the water at that point and carries it with it in its rush to the surface. The system has been extensively introduced in the South for increasing the flow of artesian wells."



MAIL RECORDS OF TRANSATLANTIC STEAMERS.

A REPORT prepared by Captain N. M. Brooks, United States Superintendent of the Foreign Mail Service, gives the following tabular statement regarding the mail service of the several transatlantic lines during the year ending June 30th, 1895:—

Cunard (New York to London viâ Queenstown).

Steamer.	No. of trips.	Average time per trip, hours.	Quickest trip, hours.
Campania	9	162·5	157·4
Lucania	11	163·0	156·7
Etruria	12	178·8	172·3
Umbria	12	183·6	170·9

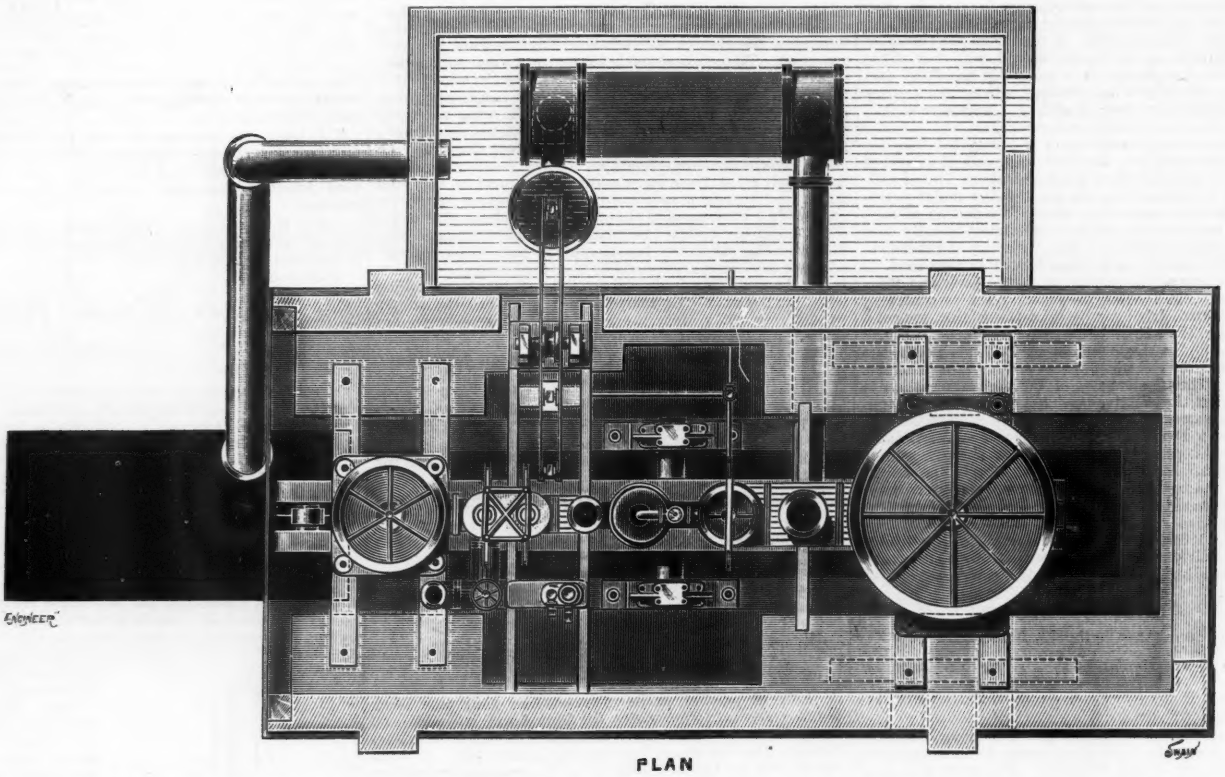
COMPOUND CORNISH PUMPING ENGINE

MESSRS. HATHORN, DAVEY, & CO., LEEDS, ENGINEERS

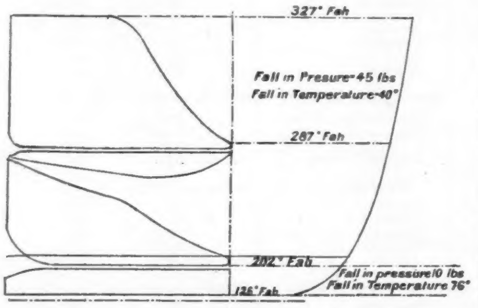


PLAN

COMPOUND CORNISH CYCLE PUMPING ENGINE.

In our annual article we mentioned the fact that Mr. Henry Davey was bringing out a compound engine working on the Cornish cycle. That engine we have much pleasure in illustrating this week. It may be well to say, for the benefit of those not familiar with the Cornish cycle, that one paramount advantage which it possesses is that the steam side of the piston and corresponding cylinder cover are never exposed to the frigorific influence of the condenser. The engine we illustrate consists of two Cornish cylinders, the high-pressure supplying the low-pressure with steam. An important factor is the feed-water heater. If exhaust steam be used to raise the temperature of the feed, not much gain is to be had because the exhaust steam has only a temperature proper to the condenser pressure, say, 110 deg. or less. But Mr. Davey uses the equilibrium steam, passing from one side of the piston to the other, which may have a temperature of 210 deg., or even more, to heat the feed-water. It matters, of course, nothing that condensation takes place, because the steam finds its way the moment the out-door stroke is completed to the condenser.

We illustrate on page 88 a large Davey engine now being made by Messrs. Hathorn, Davey, and Co., of Leeds. It has cylinders 45in. and 90in. diameter by 8ft. stroke, and is provided with 19in. plunger pumps, and also a sinking pump, for a total depth of 1000ft. The steam pressure will be 100 lb. per square inch. The distribution of steam is that of the Cornish cycle in both cylinders. The feed-water is heated to a temperature of 180 deg. to 200 deg. Fah. by means of a patented compound heater. Through one section of the heater the exhaust steam from the low-pressure cylinder passes on its way to the condenser, thus heating the feed-water to about 100 deg. Fah. The water is further heated in the second section of the heater, as explained above, by steam which passes from one side of the piston to the other during the equilibrium stroke.



The distribution of steam is illustrated by the preceding diagram:—On the right-hand side is plotted a curve of temperatures with horizontal ordinates corresponding to the pressures on the vertical line, from which the temperatures in the various points in the cycle can be ascertained, and which shows at a glance the importance of the Cornish cycle in reducing the variation in temperature in the low-pressure cylinder. In the final stage a fall of pressure of 10 lb. causes a variation in temperature of 76 deg. Fah., whilst in the first stage of the cycle a fall of pressure of 45 lb. causes a variation in temperature of 40 deg. Fah. only.

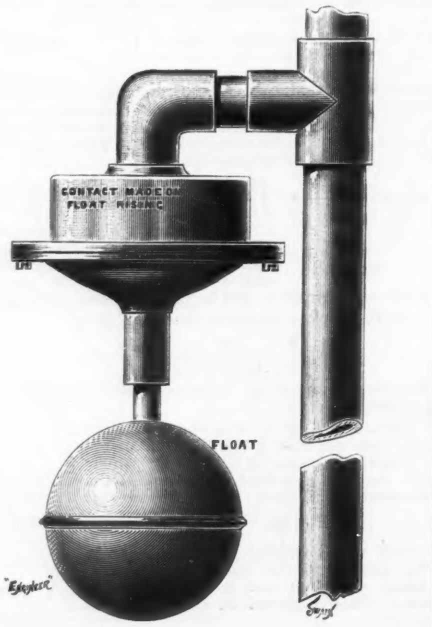
The engine is for working the Cornish system of pitwork, viz., that of a single spear rod, and is particularly suitable for draining metallifferous mines, where the working of the mine is generally contemporaneous with the sinking of the shaft, and therefore the Cornish system or stage pumping is the most suitable. Sinking is performed with a bucket pump to a depth of 200ft., when a plunger pump is put in, and the sinking is continued with the bucket pump, thus there is provided a plunger pump every 200ft. in depth. The engine valves are actuated by Davey's well-known differential gear.

AN ELECTRIC LOW-WATER ALARM.

A simple apparatus applicable to a number of purposes has just been brought out by Messrs. J. Davis and Son, of Derby and London, who have applied for letters patent.

The apparatus consists of a water—or other liquid level—alarum. The rise and fall of the liquid is caused to make or break an electric connection which rings a bell or drops a shutter, or both. The contacts are contained in water-tight metal boxes, having on the lower side a stuffing-box, through which works a plunger rod terminating in a float; the whole thing thus becomes a plunger key in a water-tight case, the motive power being the liquid acting on the float.

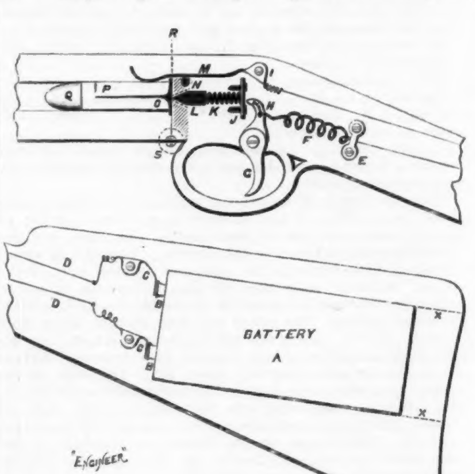
The illustration shows this apparatus arranged for high and low levels, the upper contact being made when the liquid rises and the lower when it falls. Intermediate points may be made to sound the alarum both on the rise and fall, so that it can be seen by a glance at the indicator board whether the liquid is on the rise or fall.



One feature which adds greatly to the simplicity of the apparatus is, as shown by the illustration, the manner of mounting the contact boxes, namely, on a metal pipe through which the electric wires are carried; the required distances for the alarums being thus obtained to a nicety, in addition to which all the contacts can be removed readily and simultaneously for examination or repairs and replaced in their original positions.

THE BLAKE ELECTRIC RIFLE.

The practice of firing big guns by electricity is already well established, but hitherto no practical attempt has been made to explode the shells of small arms electrically. An electric rifle has recently been designed by J. F. Blake, of New Haven, Conn., in which it is sought to carry out this principle. The source of the current is a battery A, which is fitted into the stock either from the side or from the ends. The holes B B are connected to springs C C, from which the wires D D run respectively to a spring M, bolted at I to the lock plate, and to the insulated hammer H, fixed on the upper part of the trigger G. Q is the shell containing an insulated pin, the head of which, O, projects beyond the base of the shell. If necessary, two pins can be placed parallel with each other and insulated until their points nearly meet. Between the base of the cartridge and the hammer is a pin K, encircled by a spring, and riveted into a cross plate J at one end, the other end being fitted into an insulated thimble L, the point of which nearly touches the shell pin head O. When the cartridge has been inserted and the gun closed, the spring M rests on the metal base of the cartridge.



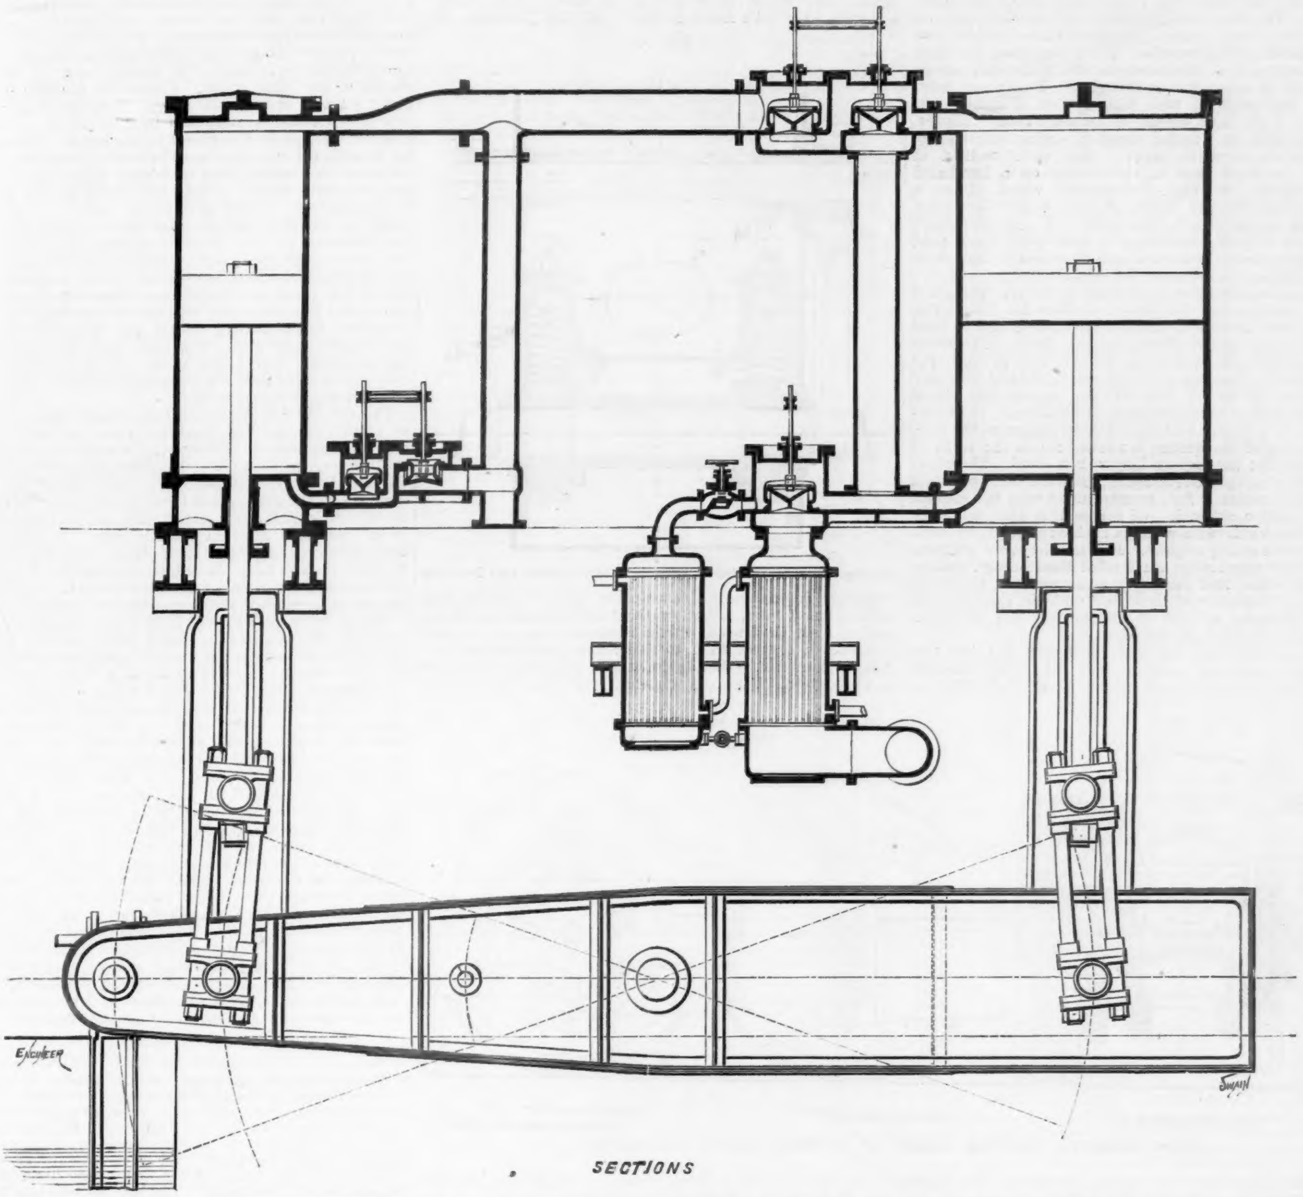
As the trigger is pulled the hammer strikes the plate J, forcing the point of the thimble L into contact with the projecting end O of the cartridge pin. An arc is established at P O, which, the *Electrical Engineer* says, explodes the contents of the cartridge.

The point of the firing pin P can be placed anywhere within the explosive powder of the cartridge, but by extending it near the bullet, as shown in the illustration, a more effective explosion of the powder is secured.

Calcutta is upon the eve, according to the last received number of the *Indian Engineer*, of a dearth of kerosine oil. "The stock on 1st December was eighteen lakhs of cases, and five lakhs only are expected between now and the 1st April. On the other hand, the consumption may be put down at four lakhs monthly or twenty lakhs in the four months, so that by the 1st April practically the whole available stock will have been exhausted. The Russian oil line from Baku to Batoum has broken down, and the European market is too bare to relieve the pressure, while only between three and four lakhs of cases can be expected from America between April and August. After that date, no doubt, the difficulty will right itself, but in the meantime the deficiency will be very considerable."

COMPOUND CORNISH PUMPING ENGINE

(For description see page 84)



SECTIONS

STEAM LOCOMOTIVES ON COMMON ROADS.

By W. Fletcher.

(Continued from page 52.)

Messrs. J. and H. McLaren's compound road locomotive and van for French parcel service is shown by Fig. 28, as described in the last article, on page 52.

Road locomotives mounted on springs—One of the most difficult problems connected with spur-geared road locomotives is the effective mounting of the engine on springs. Many of the plans introduced for this purpose have been much too complicated to be of any real service. Provisions must be made in the arrangement of the details, so that the up-and-down movement of the main axle when passing along a rough road at a fair speed shall not affect the pitch circles of any of the spur driving gear, or interfere with the proper action of the compensating apparatus. It is equally important that the springs should be free to act without being influenced by the transmission of the power through the gearing. In addition to these essential requirements, some traction engine makers insist on the axle being suspended in such a manner that one end of the axle may be higher or lower than the other without affecting the proper working of the engine. It will be seen that to successfully overcome these mechanical difficulties is no easy matter. In passing, we may remark that the mounting of chain-driven road locomotives on springs is very easily accomplished. Fig. 25 in the last article on page 51 shows how this can be done.

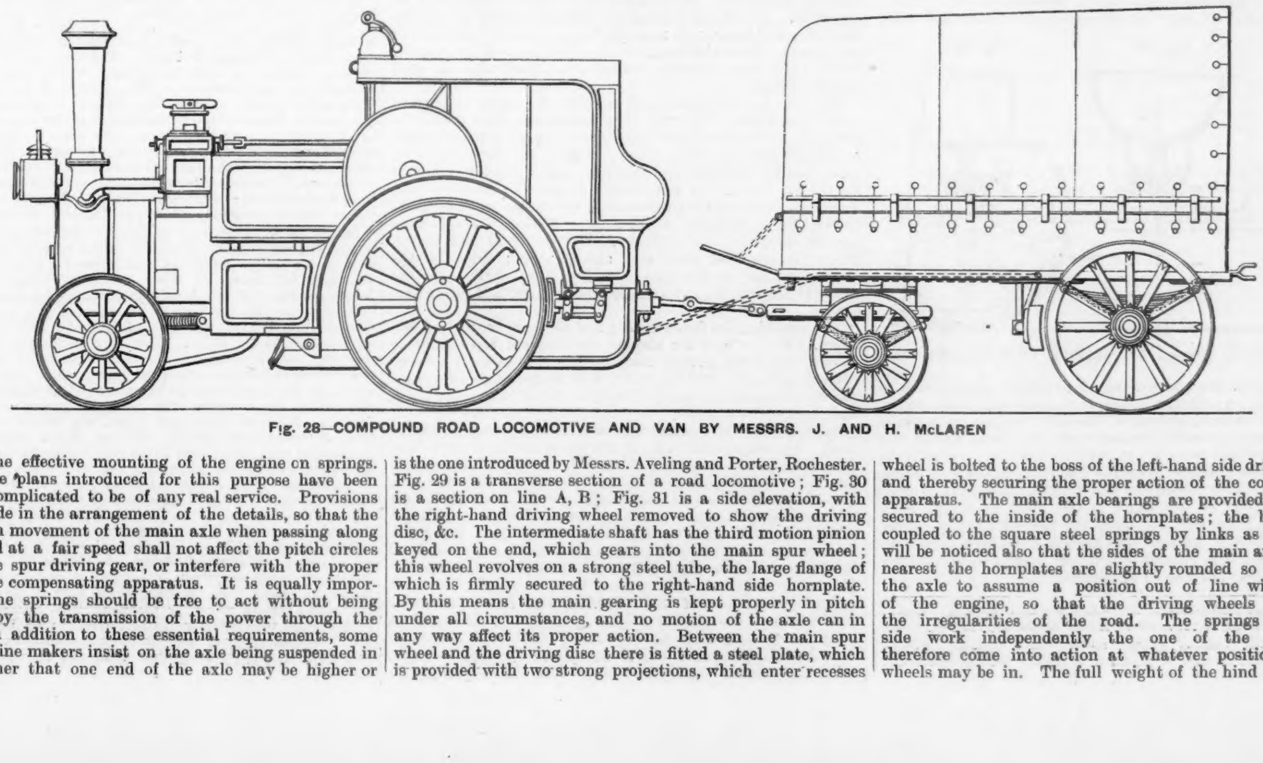


Fig. 28—COMPOUND ROAD LOCOMOTIVE AND VAN BY MESSRS. J. AND H. McLAREN

I will now proceed to describe some of the methods recently introduced for successfully mounting spur-geared road engines on springs. The latest arrangement for effecting this purpose is the one introduced by Messrs. Aveling and Porter, Rochester. Fig. 29 is a transverse section of a road locomotive; Fig. 30 is a section on line A, B; Fig. 31 is a side elevation, with the right-hand driving wheel removed to show the driving disc, &c. The intermediate shaft has the third motion pinion keyed on the end, which gears into the main spur wheel; this wheel revolves on a strong steel tube, the large flange of which is firmly secured to the right-hand side hornplate. By this means the main gearing is kept properly in pitch under all circumstances, and no motion of the axle can in any way affect its proper action. Between the main spur wheel and the driving disc there is fitted a steel plate, which is provided with two strong projections, which enter recesses in the spur wheel; while two more projections at right angles with the above enter the driving disc. This arrangement transmits the power from the spur wheel to the driving disc independent of the position of the axle. It will be seen from Fig. 29 that the driving disc is keyed to a long cannon, which forms the boss of the compensating gear centre, thereby passing the power from one side of the axle to the other. The right-hand side driving wheel and right-hand side bevel wheel are both keyed to the main axle; the left-hand bevel wheel is bolted to the boss of the left-hand side driving wheel, and thereby securing the proper action of the compensating apparatus. The main axle bearings are provided with slides secured to the inside of the hornplates; the bearings are coupled to the square steel springs by links as shown. It will be noticed also that the sides of the main axle bearings nearest the hornplates are slightly rounded so as to allow the axle to assume a position out of line with the rest of the engine, so that the driving wheels can follow the irregularities of the road. The springs on either side work independently the one of the other, and therefore come into action at whatever position the road wheels may be in. The full weight of the hind part of the engine rests evenly on the springs in the usual manner, but the details are worked out in the stiffest possible way. It will be seen that a wrought iron plate fits in between the hornplates and beneath the flanges of the axle slides. The brake rim is cast on the main spur wheel. The hornplates are stiffened by an angle iron frame fitted above the main axle slides. The whole arrangement is well worked out, and will undoubtedly be a success. Messrs. Charles Burrell and Sons' patented arrangement of spring mounting for their road locomotives was illustrated in Mr. McLaren's paper,[5] so it need not be referred to in this place. I may say, however, that engines fitted with their system of springs run smoothly at fairly high speeds on ordinary roads. Messrs. John Fowler and Co.'s spring traction engine has recently been described in these pages. But their method of mounting the front part of the engine on a laminated spring is shown by Figs. 32 and 33, which allows a free movement of the front wheels in all directions to suit the inequalities of the road. Messrs. McLaren's arrangement of spring mounting of their quick-speed road locomotives is clearly illustrated and described in Mr. John McLaren's paper,[6] so this need not be described.

Another spring arrangement is made by Messrs. Wallis and Steevens, Basingstoke. In the plans thus far dealt with, provisions have been made whereby the motion of the hind axle, due to the action of the springs, shall not interfere with the pitch circle of the spur driving gear between the intermediate shaft and axle. In Messrs. Wallis and Steevens' arrangement, shown by Fig. 34, two springs are placed between the load of the engine and the hind axle. The intermediate shaft is fixed. The up-and-down motion of the axle, due to the play of the springs, is allowed for in the teeth of the spur gearing; the cogs are longer than usual. The wheel has two pitch lines placed ⅜in. apart; between these two lines the cogs are practically flat, corresponding with the amount of vertical motion allowed. Of course this plan would be quite impracticable with a range such as is given by some makers to their spring engines. It is said by some practical men that "too much range is a decided disadvantage, making the engine dance, and causing a great wash of the water in the boiler." A range of about half an inch, they say, will be found sufficient to take off all the jar, and cause the engine to run smoothly on common roads.

It will be seen from the illustration that the two axle bearings are connected together by a very strong distance piece, so that the axle must always be parallel with the intermediate shaft when the springs are acting. The spring boxes are provided with set screws and nuts let into the castings, so that the amount of play allowed to the springs can be regulated. When the driving wheels are subjected to an exceptional shock, the axle bearings come into contact with suitable stops, so as to prevent the cogs of the spur wheel and pinion entering too deeply into gear with each other. It must be admitted that this spring engine is the simplest one in the market, but some engineers will possibly take exception to the arrangement. It is said, however, that the up-and-down motion of the axle, causing the teeth of the gearing to ride in and out to the extent of such motion, works very well in practice, and the life of the gearing is not materially shortened by this sliding process.

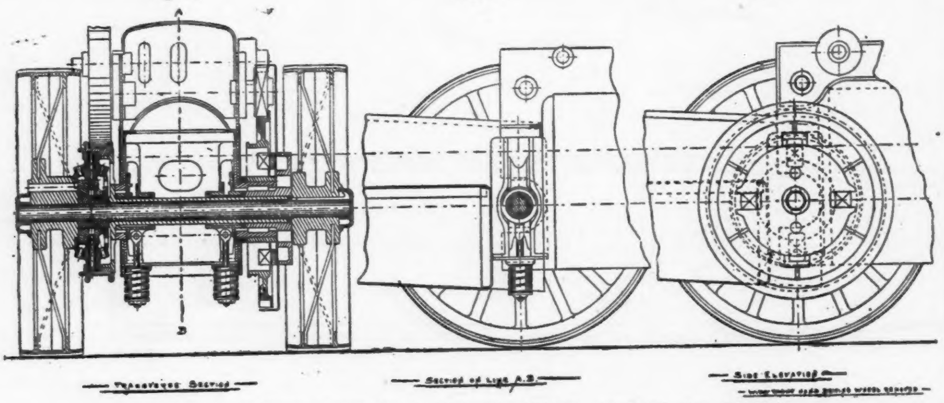

Fig. 29 Fig. 30 Fig. 31

SPRING MOUNTED TRACTION ENGINE BY MESSRS. AVELING AND PORTER

I have described some of the trains that have been used successfully for the conveyance of passengers and parcels at quick speeds on ordinary roads, and dealt with some recent methods of mounting geared traction engines on springs, without which no road locomotive can be run at a good rate with comfort and economy of repairs. It only remains for me to describe the type of engine I should propose for running light carriages for passengers and wagons for market produce at a good speed of, say, eight to ten miles an hour. Some hard things have been said about the modern traction engine, and very often by persons who have had the least experience with them. The present engine as made by the leading makers is the "survival of the fittest."

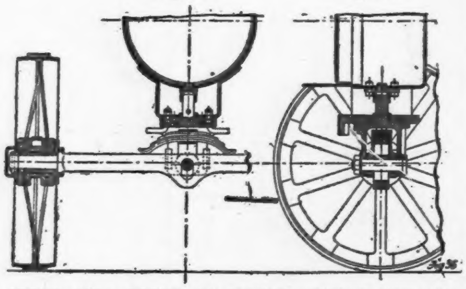

Fig. 32 Fig. 33

FRONT AXLE SPRING BY MESSRS. FOWLER AND CO.

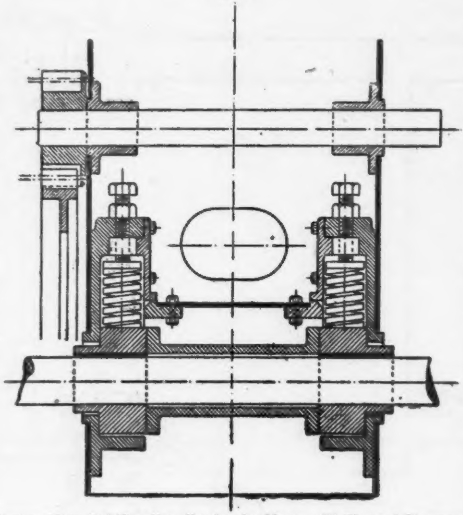

Fig. 34

Spring Mounted Traction Engine by Messrs. Wallis and Steevens

We have in the past seen some curious specimens that were to eclipse all other engines—some arranged vertically in the smoke-box, some placed on the tender, others fixed beneath the boiler barrel, and several types with all the wheels coupled. Road locomotive makers have often been urged to adopt the railway locomotive as a model, thus several attempts have been made to carry out this proposal. It would be interesting to name other types of engines and boilers, but I must not allow these curiosities to detain the reader. All that need be said respecting coupled engines, underneath engines fixed to side frames, and others of a similar character, is that as a rule only one engine was made to the pattern. These experimental types have given place to the modern road locomotive that we now possess, and there can be no question that the best remains.

The engine I should propose for passenger service would follow the lines of the modern road locomotive, with modifications in construction to make it suitable for its special work. It must have no experimental details in its construction, all the vital parts must be of the well-tried patterns. The engine would be mounted on the top of the boiler, in the usual fashion, the cylinder occupying the position of the boiler barrel near the smoke-box. At the fire-box end the various shafts are carried by the hornplates, stiffened by transverse plates forming the box brackets. In this box the first motion gearing is placed, with the clutch lever for altering the speed. The working parts of the engine will be closed in. Every detail must be carefully studied as regards efficiency and wear, and no superfluous material retained in any detail. Wrought iron and steel will be used frequently, so as to give the necessary strength, combined with the least possible weight.

The first consideration, and possibly the most important one, is the boiler. The well-tried locomotive type should be adopted. With fairly good water and careful attention, this boiler will give very little trouble. Steel has for some years been used for the shell, and this material is gaining in favour for the fire-boxes. At one time Lowmoor or Bowling iron was used. The working pressure is 150 lb. per square inch; the test pressure under water will be 240 lb. The following are the thickness of the plates:—Fire-box shell and barrel, ⅜in.; fire-box end plate and saddle, $\frac{7}{16}$in.; sides of the fire-box carried up for supporting the crank shaft, ⅝in.; the internal fire-box, ⅜in.; the fire-box and smoke-box tube plates are ⅝in.

The stays for the fire-box sides and roof will be pitched 4in. apart. Bridge bars for staying the fire-box top cannot be recommended for several reasons, but the vertical screwed stays from the fire-box top to the arch plate, as used for some railway locomotives, are preferable. These stays are light, and the fire-box crown can be kept free from scale.

Solid iron fire-box foundation and fire-door rings should be used. The water space around the fire-box should not be less than 2½in. at the bottom and 4in. at the top; the fire-hole ring is 2in. square, the fire-box front plate being dished to suit. The longitudinal seams are double riveted, and so is the circumferential seam connecting the saddle plate with the barrel. Some makers use 2in. tubes, others 2¼in.: the spaces between the tubes should not be less than 1in.; both ends of the tubes should be expanded in the tube plates and beaded. The boiler barrel must be made as short as possible, so as to reduce the amount of water carried, and the mean water level will be less affected by the gradients of the road. A good fitting ashpan is an important item, with a damper door back and front; a swivel damper in the chimney box, below the exhaust nozzle, is useful. The chimney must be provided with a hinge, and facilities for lowering and raising it when low bridges have to be encountered. No sparks must be emitted, an effective spark catcher must be fitted, and the smoke-box door must be provided with a central handle that will pull the door tightly up to the smoke-box front. As far as possible the engine must be smokeless, coke must be mixed with good coal, and the damper arrangements such as to prevent the emittance of smoke. The fire-door will be of the sliding pattern. A good set of fire-bars are essential, the air spaces should be as narrow as possible, and all the spaces should be the same width. Unless the fire-bars are nicely made a waste of coal will ensue, I should prefer wrought iron deep fire-bars securely held in their places. A manhole properly strengthened is placed in the barrel. The facilities for clearing out the boiler must be carefully studied; in some instances the saddle plate is flanged under the hydraulic press to a large radius, so that two mudholes can be placed in the corners. Every part of the boiler will be riveted under the machine, and the very best workmanship must be bestowed upon it. For a single cylinder 9in. diameter, and 12in. stroke, 160 square feet of heating surface, and 6 square feet of grate area would be required. For a compound engine with a high-pressure cylinder 6½in. diameter, a low-pressure cylinder of 10in. diameter, both the pistons with 12in. stroke, 145 square feet of heating surface and 5½ square feet of grate area should be allowed. The noise from the exhaust must be suppressed. Two water gauge fittings are essential, and they should be of such a safe character that the steam is shut off the moment a glass breaks.

The fire-box side plates are carried upward and backward so as to form the box brackets; there are two transverse plates firmly riveted between the side plates, and held by angle iron to the arch plate. Another plate will be placed at the top for further stiffening the whole structure; this top plate covers the gearing and forms a neat tray. The carriages for the crank shaft, two countershafts, and the main axle must be let into bored holes in the side plates, the rivets merely keeping the bearings up to their places. The carriages should be made of steel so as to reduce the weight. The plates of the box brackets must be machine riveted. If the engine is mounted on springs, the above description must be modified.

The cylinder will be made in two parts, the shell or casing will be in one casting; the liner is made of hard metal and forced into the casing, the annular space around the liner is of ample capacity, in order to act as a steam dome and prevent priming. The jacket steam supply and drainage must be so carried out that the circulation of the steam in the annular space is maintained. At the highest part of this dome the stop valve should draw its supply of steam for the working cylinder. All the passages for the steam should be of sufficient area to admit of a high piston speed. The cylinder will be placed on the boiler as near to the smoke-box tube-plate as possible, and be provided with a strong flange all round the base, the bolts in which will be arranged about 4in. pitch; a sufficient amount of surface must be allowed so as to make a reliable joint between the foot of the cylinder and the boiler barrel; this will prevent any springing of the barrel plate. It is usual to make the steam enter the cylinder as near to the smoke-box as possible. A double spring Ramsbottom safety value is mounted on the top cover of the cylinder. The proper lubrication of the piston and the slide valve is a very important matter, and must be well attended to. The greater part of the cylinder will be carefully lagged and covered with sheet steel. A single cylinder of 9in. diameter and 12in. stroke may be adopted.

(To be continued.)

Street Subways for Pipes.—At the meeting of the London County Council on Tuesday it was moved, "That it be referred to the Highways Committee to consider and report without delay on the expediency of the Council applying to Parliament for power for the Council and the local authorities to construct subways under the streets of London, for the reception of the tubes and wires of the gas, water, electric, and other companies, and to charge rents for the same." This was seconded and agreed to, with the addition of a reference to the Parliamentary Committee.

Institution of Mechanical Engineers. — The forty-ninth annual general meeting of this Institution will be held on Thursday evening, January 30th, and Friday evening, January 31st, at 25, Great George-street, Westminster. The chair will be taken by the President at half-past seven p.m. on each evening. The annual report of the Council will be presented to the meeting on Thursday. The following resolution will be moved from the chair: "That in accordance with No. 31 of the Articles of Association, the Council be hereby authorised to borrow moneys for the purposes of the Institution on the security of the property of the Institution, or otherwise at their discretion." The annual election of the president, vice-president, and members of the Council, and the ordinary election of new members, will take place at the meeting on Thursday. The retiring President, Professor Alexander B. W. Kennedy, LL.D., F.R.S., will induct into the chair the president elect, Mr. E. Windsor Richards. The appointment of a professional accountant, to audit the accounts of the present year, will be made by the members on Thursday, and his remuneration fixed. The present auditor, Mr. Robert A. McLean, chartered accountant, offers himself for re-election at the same remuneration as at present, namely, 25 guineas. The following papers will then be read and discussed, as far as time permits:—"Telemeters and Range Finders for Naval and other Purposes," by Professors Barr and Stroud." "Calculation of Horse-Power for Marine Propulsion," by Lieutenant-Colonel Thomas English, Thursday. "Notes on Steam Superheating," by Mr. W. H. Patchell, of London, Friday.

Death of an American Engineer.—Mr Alfred E. Beach, for nearly fifty years one of the editors of the *Scientific American*, died at his home in New York City on January 1st, aged seventy years. Mr. Beach was the son of Moses Y. Beach, who established the New York *Sun*, but outside of a short time in his father's office, his entire business life had been as a member of the patent soliciting firm of Munn and Co., which he established in 1846 with his former schoolmate, A. D. Munn. The firm purchased the *Scientific American*, and its editorship was undertaken by Mr. Beach, and he has been its responsible editor all these years. But neither that work, nor the direction of the extensive patent business of the firm absorbed all his energies. The list of his inventions is an important one, and would alone have given him distinction. He was a man of remarkable energy, with an active mind, of natural mechanical bent, which well fitted him for his business. As early as 1852 he exhibited a typewriting machine, which received a gold medal at the Crystal Palace exhibition in New York as one of the most important and ingenious inventions exhibited. It had practically all the devices of the present typewriting machines. He devised a pneumatic tube system for carrying mails, and a pneumatic railroad, of which an experimental section—elevated—was put in operation. The Beach Pneumatic Transit Co., of which Mr. Beach was president, built a section of underground road in Broadway, New York, in 1869, being part of an underground pneumatic system which he planned. This section of road was built without interfering with street traffic, by the Beach hydraulic shield, similar ot those used at the St. Clair tunnel, on the City and South London underground road and elsewhere.—*Railroad Gazette.*

[6] "Steam on Common Roads," by Mr. John McLaren. Excerpt, "Minutes of Proceedings' of the Institute of Civil Engineers, vol. ciii., 1890-91.

RAILWAY MATTERS.

Though the railroad system of the United States increased from a total length of 114,712 miles in 1882 to 178,709 miles on June 30th, 1894, or 56 per cent., the aggregate sum paid in dividends during the latter year was only 95,575,976 dols., being 6,455,458 dols., or 6½ per cent., less than during the former.

The Parliamentary plans have been deposited by Sir John Fowler, Bart., C.E., and Mr. James C. Inglis, the engineers to the Great Western Railway Company, for the construction of that company's proposed South Wales and Bristol Direct Railway. The total cost of carrying out this scheme, according to the deposited estimate, is £1,116,348.

Besides the Ahmedabad-Parantij Railway, the Bombay-Baroda and Central Indian Railway Company is now, says *Indian Engineering*, engaged in constructing a railway on the 2ft. 6in. gauge from Ankleswar to Sarsa for the Rajpipla State, and from Vishvamitri to Padra on the same gauge for the Baroda State. Mr. Whately, who was acting as resident engineer in Bombay during the absence of Mr. Wolff, has been placed in charge of these two lines.

Information has been received at the India-office from the Public Works Department of the Government of India that Berhampore-Rambha section of the East Coast State Railway, a length of 29·5 miles, was opened for the public carriage of passengers on October 15th, 1895, and that the Nankan-Mohnyin section and the Katha branch of the Mu Valley State Railway, 73¾ and 15 miles long respectively, were opened for the public carriage of passengers on October 21st, 1895.

The average charge for carrying a ton of freight one mile *via* thirteen of the most important railroads in the United States during 1865 was 3·08 cents; 1870, 1·80; 1875, 1·36; 1880, 1·01; 1885, 0·83; 1890, 0·77; and 1893, 0·76. These railroads performed one-third of the entire freight transportation during 1893, and from the figures given it appears that 76 cents would pay for as much transportation over their lines in 1893 as could have been obtained for 3·08 dols. 28 years earlier.

The method of preventing electric street tramway accidents adopted by the Steinway Electric Railway, of Long Island City, N.Y., is worthy of adoption by overhead and cable car lines in general. In accordance with an agreement made a year ago, *Engineering News* says, prizes of 25 dols. each were paid each motorman and conductor who got through the year without an accident to his car. The full prize was given to 98 men, and lesser prizes were given to 94 men who had served less than a year, over 4000 dols. in all being distributed.

The railway has been opened to Woolgangee, within 40 miles of Coolgardie, but, owing to the increase in the quantity of goods coming forwards, teamsters have announced their intention of adhering to the present rate of freight, which is £12 per ton. Notwithstanding the fact that the railway has advanced 60 miles, carriage is more expensive now than it was last year. The *Railway News* says large quantities of machinery are waiting removal, and more teams are urgently required. Labour of every description is also very scarce, owing to the large number of buildings going up.

The United States Government report of mail car accidents for the year ending June 30th, 1895, records 33 cases in which mail was damaged by oil and three cases in which the subsequent destruction by fire was caused by oil lamps. The use of compressed gas and Pintsch lamps is recommended. The great improvement made in these lamps and the establishment of compressing plants at so many of the principal cities leaves no reasonable excuse for not using gas and taking away this one element of danger to mail clerks and mails. The same is true of passengers and passenger cars, in quantity of light, cleanliness and safety.

During the year 1895, according to the *Philadelphia Record*, the Baldwin Locomotive Works built 401 locomotives. The output is about 28 per cent. in excess of that of the previous year, 1894, when but 313 locomotives were built, and about 52 per cent. of the product of 1893, when 763 locomotives were sent out by the firm. Of the 401 locomotives constructed during the past year, 162 were for export. There are now in hand orders for 90 engines. Of this number 20 constitute the balance of the order placed some months ago by the Russian Government. These 20 engines are rapidly approaching completion, and will be ready for shipment by the latter end of January.

The New Central and Hudson River Railroad Company has increased the scheduled speed of its Empire State express from an average of 51 miles an hour to 53·33 miles an hour between New York and Buffalo. For more than four years this train has made its daily run of 440 miles in 520 minutes, including four stops and 28 slow downs. Its new time of 495 minutes is not that of an experimental run, but is scheduled for daily service between New York and Buffalo until a further reduction becomes practicable. The speed of the best trains of foreign nations is:—England, 51·75 miles an hour; Germany, 51·35; France, 49·88; Belgium, 45·04; Holland, 44·73; Italy, 42·34; Austria-Hungary, 41·75. The *Railroad Gazette* says America now heads the list with 53·33 miles an hour to the credit of the Empire State express.

The French Ministry of Public Works has recently addressed to the various French railroads a circular letter with regard to some of the complications arising from the fact that enginemen are paid premiums for time made up. It is believed that certain dangers follow the custom of giving such premiums, because the enginemen are tempted to run too fast when they have lost time. These dangers are modified, it is true, by the premiums for fuel saving, and by the rules fixing the maximum speeds. It is thought important to avoid excessive speeds, and yet it is no less important to avoid delays, which disarrange the traffic and cause complaints from the public, and which are often the cause of accidents. The railroad companies are requested to make a study and report concerning the systems of premiums, both for time gained and for fuel saved, in their relative effects, and also to consider and report upon the practicability of a general use of registering speed records.

The new railway construction in the United States, in 1894, was reported at 1760 miles, and that seemed to be as low a record as was likely to be again made. But the total for this year is about 300 miles less than that, being 1428 miles. This will, no doubt, be increased by later returns from companies which are still laying track. But it shows that railroad extension is no longer a very important factor in the industrial concern of the nation. That has been true for some years, but there have been so many adverse conditions stopping the expansion of many enterprises just as severely as railroad building could be affected, that there has been a feeling that with more favourable economic conditions, railroad building would again become of great interest and influence. We apparently should have to conclude that railroad extension hereafter will be small, as compared with what has been done in quite recent years. The following shows the new track laid, by different States:—Alabama, 22·5; Arizona, 65·3; Arkansas, 38; California, 65·5; Colorado, 33·9; Florida, 38·5; Georgia, 67·7; Illinois, 41·8; Indiana, 14·9; Ind. Ter., 144; Iowa, 11·1; Kansas, 18; Louisiana, 17; Maine, 82; Maryland, 2; Michigan, 49·5; Minnesota, 23·86; Mississippi, 10; Missouri, 50; Montana, 5·4; New Jersey, 4·6; New York, 61·6; North Carolina, 44·3; Ohio, 72; Oklahoma, 49; Pennsylvania, 83·5; South Carolina, 1; Texas, 186·5; Utah, 4; Virginia, 14; Washington, 2·6; West Virginia, 68·5; Wisconsin, 35·8; total, United States, 1428·4.

NOTES AND MEMORANDA.

The Gas Company of Paris has in its shops at Tory a 5-horse power de Laval steam turbine which holds a high record for endurance. It operates an exhauster 21 hours a day, and has now run for 5300 hours. After 1700 hours it was stopped for a brake test. Since then it has been running 3600 hours continuously. The peripheral speed of the disc being 525ft. per second, 1,900,000 miles in all, or about 78 times the circumference of the globe, have been made since it started, and about 53 times the circumference in 150 days since it has been running without interruption. The result is the more remarkable as the machine is running without attendance. Someone has to fill up an automatic oil feed every twelve hours; that is all the attention it has needed; 120 lb. of oil have been consumed each month

An experiment has been made at Cleveland, Ohio, in the use of trap rock as a paving material, and it promises to result very satisfactorily. A foundation of crushed limestone, 10in. thick, is laid; above this is placed the trap rock, 8in. thick, arranged in three layers—coarse screenings, fine screenings, and dust. The trap is obtained from quarries near St. Joseph's Island, St. Mary's River, at the north of Lake Huron. The rock can be had for little more than the cost of quarrying and transportation, and the pavement as laid down cost 3·10 dols., 3·19 and 3·65 dols., according to grade. Two miles have been laid in Cleveland, and it is said to promise well. Trap is used extensively in Germany for road making. *The Quarry* says, however, that wherever trap rock has been used it has generally been condemned on account of its liability to become slippery by wear, even when broken up and used in small pieces.

Mr. Alexander Kellas and Professor William Ramsay have found a trace of the new gas argon in the combustible gas from the spring known as "Allhusen's Well," Middlesborough. An incombustible gas from another well at the same place, says the *Globe*, was found to contain about ½ per cent. of argon. Moreover, the gas from a boiling spring, near Reykjavik, Iceland, has even a greater proportion of argon than common air, namely, 1·14 per cent. No helium could be detected in the gas. The fact that breathed air contains a slightly higher percentage—1·21—of argon than ordinary air has led Mr. Alexander Kellas to suppose that more argon is emitted by the blood than is absorbed in breathing, or that the air had been confined over water during breathing. In any case it would appear that argon like nitrogen does not play an important part in the animal ecomony, except as a diluent of the oxygen, which is so necessary to sustain life.

In a paper on "Urban Roads and Footways" recently read by Mr. J. Julian, Cambridge, before the Institution of Junior Engineers, the author remarked that in macadamised roads it was more economical to strengthen the foundation than to use a thick layer of other material between foundation and surface. The materials employed for foundation, and, to a somewhat lesser degree, for surface, were shown to be governed by local circumstances. Examples of cost in three localities amounted to practically the same per yard super.—4s. 3d.; but the problem in most places was, perhaps, to produce a road as good as possible for a fixed figure, the various items varying considerably. Details were also given of the total cost per yard super. of pavings on concrete foundations, viz., granite 11s. 9d., hard wood 15s., and asphalte 11s. The limiting gradients in ordinary cases were, asphalte 1 in 60, wood 1 in 25, macadam 1 in 20, and granite 1 in 15; but there were instances of macadam roads as steep as 1 in 6.

Numerous experiments during the last few years relating to the transmission of heat have shown that much of the earlier work on this subject was interpreted too broadly, and even yet there are questions remaining to be solved by experiment. At the last meeting of the British Association a paper was read by Mr. W. G. Walker on "Transfer of Heat through Plates with Differently-arranged Surfaces," as, for instance, in Servé tubes, in tubes with no ribs, with ribs outside, and with ribs inside and outside; but his ribs were soldered on to the tube, and did not form part of the material as in Servé tubes. Lately Mr. Bryan Donkin, in conjunction with Lieutenant-Colonel English, has been making many experiments, which will probably be shortly presented in a paper for reading. A Research Committee was some time ago appointed by the Institution of Mechanical Engineers, for making experiments on a special experimental steam engine. There has also been a Research Committee appointed for investigating the temperatures and pressures in gas engine cylinders. The experiments on the condensation of steam have been going on for some little time at the University College, under the Steam Jacket Research Committee.

A paper on "Solid Carbonic Anhydride" was recently given in the *Comptes Rendus* by Mr. P. Villard and R. Jarry:—Dry carbonic anhydride cooled and solidified in a wide tube melts at −56·7 deg., and its vapour pressure at this temperature is 5·1 atmos.; it resolidifies at the same temperature, and shows the same vapour pressure. The temperature of solid carbonic anhydride under atmospheric pressure is −79 deg. In making this determination, precautions were taken to protect the thermometer from radiation from surrounding objects. Regnault found −78·16 deg., and Pouillet −79 deg.; contrary to the usual statement, the addition of ether does not reduce the temperature, and the minimum of −79 deg. is only obtained when the carbonic anhydride snow is in excess. The heat of dissolution of the solid in the ether is so small that it can only be recognised if the ether has previously been cooled to −79 deg. Methylic chloride behaves differently, and the solid carbonic anhydride at temperatures below −65 deg. dissolves in it without any evolution of gas, and when the liquid is saturated the temperature is −85 deg., a result due to the dissolution of the solid. By passing a current of dry air through the mixture its temperature can be reduced to −90 deg. Under a pressure of 5 mm., the temperature of the solid anhydride is −125 deg., and it evaporates very slowly under these conditions. It follows that it should be possible to liquefy oxygen with carbonic anhydride only as the cooling agent and with ordinary appliances.

Photographs and photographic slides showing objects such as the bones of the hand of a living person were exhibited and explained at the Camera Club on the 16th inst. by Mr. A. A. Campbell Swinton. The source of influence or light used was a Crooke's radiant matter tube. He has some experiments in progress with metal plates of different thickness, by which he hopes to find whether there is any analogy between their relative conducting powers for heat and electricity and their porosity for these radiations. He showed two pictures, or rather shadows, one being taken in a wooden camera back, and the other through an aluminium plate. These included coins, a leather purse, in which the coins were distinct, while their receptacle was all but invisible, and pieces of wood to which had been affixed wafers of tinfoil—the wood being transparent to the radiations and the metallic wafers opaque. He showed prints from the original plates, but he hesitated to use the terms negative and positive, for it was difficult to say if such terms were allowable. He regarded Professor Röntgen's experiments as an amplification of Lennard's, who had experimented some time back with a Crooke's tube, in which was fitted a window of aluminium, and had found that a photographic plate was to some extent sensitive to similar radiations. What these radiations are it is impossible to say. There are two theories, one indicating that they move in waves, and the other that they consist in the projection of particles of matter, and if it be correct the ordinary laws of optics cannot apply. He could not learn that Professor Röntgen employed any special apparatus, but he himself found that no effects were evident when an ordinary induction coil was employed. He happened to have in use a lot of apparatus for high frequency phenomena, and with this his experiments had been brought to a successful issue.

MISCELLANEA.

The Main Drainage Committee of the London County Council reported on Tuesday that the total quantity of sludge sent to sea during the year 1895 from the northern outfall at Barking had been 1,408,000 tons, and from the southern outfall at Crossness 761,000 tons, making a total for both outfalls of 2,169,000 tons, or an average of about 41,712 tons weekly. These figures, compared with those of 1894, showed an increase of 80,000 tons in the quantity removed at the northern outfall, and of 37,000 tons at the southern outfall, or a total increase for the year of 117,000 tons.

The Board of United States ordnance officers appointed to watch the trials of the three 15in. pneumatic guns mounted at the entrance to San Francisco harbour, have reported to General Flagler that the battery has more than fulfilled all requirements. According to the *Army and Navy Gazette*, the trials included traversing, elevating, and firing air charges to test the capacity of the plant, and about 150 dummy projectiles were fired in three hours. Three sub-calibre 8in. shells were thrown to distances of 1500, 2000, and 2500 yards successively, and one charge with 100 lb. of dynamite was thrown upon the rocks two miles across the bay.

Two horses attached to a brougham ran away in New Bond-street on Tuesday afternoon, and just opposite the Albemarle Hotel came into collision with a gas lamp. The driver was thrown from his seat and killed at once, as was also the driver of a hansom which just then collided with the brougham. Three ladies in the carriage were hurt, and one of the horses had to be shot. It is not often that two drivers are killed by one such collision, but the death of one at a time is somewhat frequent. These accidents with horses occasion but passing notice, but if one such accident occurred, or in future occurs, with motor carriages, the cry against them will be loud and long, as it has in the past if an accident happened with a road locomotive.

The fact that calcium carbide is now obtainable commercially has been ingeniously applied by M. G. Trouvé for the purposes of domestic lighting. The principle of his lamp is that of the "Kipp," used in chemical laboratories, in various forms, for the production of hydrogen sulphide and other gases. The mode of arranging the contact of the water and carbide had to be carefully worked out, as an ordinary "Kipp," charged with calcium carbide and water, gives such a vigorous evolution of acetylene as to be unmanageable. An estimate of the working cost of the lamp compared with that of coal gas is favourable, *Nature* says, to the former in Paris, where gas is costly—7s. per 1000ft.—but in London, if the carbide could be obtained at the same price—4½d. per lb.—the cost would still be double that of ordinary lighting gas.

The ambition of the Water Committee of the London County Council is not to be baulked by any considerations of public expense. On Tuesday they submitted a report asking that they shall be requested to go into the whole question of supplying the metropolis by aqueducts from the Welsh lakes. The scheme is, no doubt, imposing. But the question asked the other day has not yet been answered, and we are glad to see that the *St. James's Gazette* is now refusing to adopt the cry for a new source of supply, and asks, "Why should we convey filtered water at the ratepayers' cost just for flushing drains and watering streets? If the amount of pure water now available were reserved for drinking, cooking, and washing, it would more than meet the needs of a population larger than London is likely to contain fifty, even a hundred, years hence."

The official report to the Board of Trade on the working of the Boiler Explosions Acts, 1882 and 1890, during the year ended June 30th last, states that eighty-seven preliminary inquiries and twenty-seven formal investigations were held, forty-three persons having been killed and eighty-five injured by boiler explosions. The total number of cases inquired into showed a small increase upon that of the preceding year, and the number of persons killed, as also the number injured, was larger than in any year since the Act of 1882 came into force. Several exceptionally serious cases were dealt with, and more than half the total number of deaths resulted from four explosions. The year was, moreover, remarkable for a period of unusually severe frost, one result being a large number of explosions of boilers used for heating public buildings and places of business. There did not, however, appear to be any increase in laxity of management or inspection on the part of steam users or boiler insurance companies, and the figures did not show any general increase in the number of serious boiler explosions.

At a meeting of the Society of Arts, on Wednesday evening, a paper was read by Mr. F. Grierson on "The Supply of Sea Water for London." Mr. Grierson described the scheme, which will come before Parliament in the ensuing session, by which it is contemplated to construct conduits for the conveyance of sea water to London from South Lancing, in Sussex. The present intention was to supply nine or ten million gallons a day. One of the main purposes for which sea water could be usefully employed in London was for street-watering. As nearly as could be ascertained, about forty million gallons of fresh filtered water were now daily consumed in London for non-domestic purposes. The cost of the complete carrying-out of the project would be £450,000, and the works could be completed in about two years. There would be less dust and smell, and more cleanliness in the streets; watering would be less frequent and more efficient; the road surface would be more durable; the sewers would be less offensive; the cost to the ratepayers would be less; hospitals and schools would be provided with additional aids to health; every house could be furnished with its own sea bath; the saving of fresh water would be very great, practically adding 25 per cent. to the present supply, and this would make the proposed expenditure on an enormously costly aqueduct system from Wales a more absurdly preposterous scheme than ever.

The new war vessels with which the French Government propose to proceed this year are the Henri IV., ironclad; the Jeanne d'Arc, first-class cruiser; and the Dunois and La Hère, first-class despatch boats. The plans of the Henri IV. are not yet finally approved, but she will have a displacement of 7000 tons, while her length will be 283ft. 4in., her breadth 66ft. 8in., and her draught of water 23ft. 4in. She will be built entirely of steel, her engines will work up to 7000-horse power, and she will be propelled by three screws. Her estimated maximum speed is 15 knots per hour. At 10 knots per hour she will be able to steam 6000 miles. The Henri IV. is to be laid down at Cherbourg in the course of the second half of this year, and she is to be ready for sea by April, 1900. Her estimated cost, including engines and equipment, is £627,163. The Henri IV. has been designed by M. Bertin, who has also prepared the plans for the Jeanne d'Arc. This new cruiser is to have a displacement of 11,000 tons, and she is to be 476ft. 8in. in length by 64ft. 8in. in beam. Her draught of water is to be 27ft. 8in., and her hull is to be wholly steel. She is to be fitted with vertical engines working up to 28,000-horse power. Steam will be supplied by multitubular boilers on the Normand system. The Jeanne d'Arc, which is to be fitted with three screws, is expected to attain a maximum speed of 23 knots per hour. The Jeanne d'Arc is to be laid down at Toulon this month, and she is to be ready for sea by October, 1899. The Spanish Government has ordered two torpedo destroyers in England. They are to steam at the rate of 28 knots per hour. The Brazilian Government has recently placed an order for two ironclads with the La Seyne shipbuilding yards—France. The *Standard* says the Brazilian Government will also shortly place contracts for three 4000 tons, 19½ knots, protected cruisers, ten ordinary torpedo boats, eight torpedo boat destroyers, and five submarine torpedo boats.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

R. S.—*All the information we possess on the subject has been published. We will endeavour to obtain replies to your questions.*

L. R. C. S.—*Apply to Messrs. Roots and Venables, 100, Westminster Bridge-road, London, and to the Britannia Company, Colchester.*

R. E. S. (Birmingham).—*The most economical method consists in blowing live steam directly into the water to be heated. It is also much the cheapest as regards first cost.*

THE CALYX DIAMOND BORING CROWN.

(*To the Editor of The Engineer.*)

SIR,—We will be obliged if you will allow us to ask through your columns for the name of the makers of the new Calyx crown, as we are unable to obtain it out here.

M. AND F.

Johannesburg, December 23rd.

STEEL PEN MAKING MACHINERY.

(*To the Editor of The Engineer.*)

SIR,—We require the name of makers of steel pen machinery, and will be obliged if you will allow us to ask for them in your columns.

St. Petersburg. H. D.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, January 28th, at 8 p.m. Paper: "Recent Developments in Gas Engines," by Mr. Dugald Clerk, Assoc. M. Inst. C.E. Friday, January 31st, at 8 p.m. Students' meeting. Papers: "Ironfounding in Green Sand," and "Malleable Cast Iron," by Mr. F. A. Lart, Stud. Inst. C.E. Dr. W. Anderson, C.B., F.R.S., Member of Council, will preside.

INSTITUTION OF MECHANICAL ENGINEERS.—Thursday, January 30th, and Friday, January 31st, at 8 p.m., at 25, Great George-street, Westminster, by permission of the Council of the Institution of Civil Engineers. Thursday, January 30th. Papers: "Telemeters and Range Finders for Naval and other Purposes," by Professors Barr and Stroud. "Calculation of Horse-power for Marine Propulsion," by Lt.-Colonel Thomas English. Friday, January 31st. Paper: "Notes on Steam Superheating," by Mr. William H. Patchell, of London.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, January 28th, at 3 p.m. Lecture: "The External Covering of Plants and Animals: Its Structure and Functions," by Professor Charles Stewart, M.R.C.S., F.L.S. Thursday, January 30th, at 3 p.m. Lecture: "Dante," by Philip H. Wicksteed, Esq., M.A. Friday, January 31st, at 9 p.m. Discourse: "National Biography," by Sidney Lee, Esq. Saturday, February 1st, at 3 p.m. Lecture: "Realism and Idealism in Musical Art, with Musical Illustrations," by Professor C. Hubert H. Parry, D.C.L., Mus. Doc., M.A.

DUNDEE INSTITUTE OF ARCHITECTURE, SCIENCE, AND ART.—Thursday, January 30th, at 8 p.m. Paper: "Locks and Keys, Ancient and Modern: Their Development, Ornamentally and Mechanically," by Harry W. Chubb, Esq., Assoc. Mem. Inst. C.E., London.

SOCIETY OF ARTS.—Monday, January 27th, at 8 p.m. Cantor Lecture: "Alternate Current Transformers," by Dr. J. A. Fleming, F.R.S. Tuesday, January 28th, at 8 p.m. Foreign and Colonial Section. Paper: "Stamboul, Old and New," by Richard Davey. Wednesday, January 29th, at 8 p.m. Paper: "Standards of Light," by W. J. Dibdin, F.C.S. Captain W. de W. Abney, C.B., F.R.S., will preside.

THE ENGINEER.

JANUARY 24, 1896.

FOREIGN COMPETITION IN THE IRON TRADES.

THE investigations which have recently taken place on the Continent, and which were set on foot by the British Iron Trade Association for the purpose of ascertaining how far foreign competition in this industry is affecting the British trade, have now been embodied in a lengthy report, which was drawn up by the delegates, and has now been formally adopted by the Association. The delegation consisted of seven representatives of British masters in the trade and seven representatives of the working men, and their combined efforts have produced a document which is very interesting to the student of international trade matters. No subject is more open to misrepresentation and more persistently misrepresented than that which has to do with industrial problems, whether in their commercial or labour aspects, for there are nearly always two bitterly opposed sides to them, and the statements of both are too often extremely reckless and exaggerated. In the present instance, however, this argument does not hold good, as the joint committee formed of the two contending elements had in view the common and laudable object of ascertaining, as practical men, why it is that continental firms can in many cases undersell the British producer, and of offering suggestions as to how such a state of affairs can be remedied or lessened. In England we have, on the one hand, become so used to the cry, from the masters' point of view, that wages are far too high in comparison with continental standards; while from trade unionists we hear with equal emphasis that the working man is sweated and downtrodden, that it has become very difficult for the most unbiassed and well-meaning individual to strike an accurate mean between the two extremes. It is, therefore, distinctly gratifying to learn that, according to the opinion of the iron trades' representatives, the working man in this country, in these industries at all events, is neither overpaid nor underpaid. His salary is higher than that of his continental brethren, but we are told that the difference between English and German wages is not so great as is generally supposed. Now, it is precisely on this point that statistics would have been extremely valuable, but the report does not give us any figures on the subject.

We are aware that the collection of accurate details as to wages on anything like a comprehensive scale is at once an extremely arduous and delicate undertaking, and that superficial information on the subject would stand a great chance of being rather misleading than otherwise; but it would have been interesting to know in a general way what the difference in wages between us and our neighbours really amounts to. The members of the delegation must have arrived at some basis of their own when they stated that the difference is not so great as is generally supposed. But what is the general impression? We do not know, and we do not believe that any employer in the iron trade has a very accurate knowledge on the subject. This is where the report fails, and leaves matters exactly as they were before as far as real explanations are concerned. It tells us that Belgian wages are lower than German, but this fact has been well known to most iron employers for a long time past. A useful point, however, with regard to the labour question is noted, viz., that the extremes of payment, so noticeable in Great Britain, have no equivalent on the continent. For instance, while in Glasgow engineers are paying their men at least 25 per cent. less than London firms are obliged to pay similar men for similar work, there is no such variable scale of wages among any of our Continental competitors. The logic of so great a variation is by no means apparent, and the Fatherland, whatever else we may have to say about it, is to be congratulated on managing the equalisation of its wages better than we do.

The most instructive and interesting portion of the report, however, is that which deals with the reasons other than labour which tend to lessen the cost of foreign products, and here, at all events, we have some data to go by. The most important of these is the extraordinary difference in the cost of internal transport. In this the Englishman is enormously handicapped, and the report does well to emphasise this fact. From the figures given, it would appear that Belgian producers can send their material by rail to Antwerp, unload it, place it on board ship, bring it to London, and unship it at a much lower cost than is paid by the Englishman to transport his goods from the Midlands to the Metropolis. Another striking illustration of the disadvantage under which we labour is given with regard to "one of the largest works in Germany, whose premises are situated over 150 miles away from any port, but who can send their finished iron and steel through Belgium by rail, and ship it at Antwerp for 3s. 6d. a ton, while the cost of bringing the same class of material from, say, Staffordshire to London, less than 140 miles, would amount to about three times that sum. The delegation have come to the conclusion that were the English railway rates on a par with those on the Continent, we could successfully defy foreign competition in this industry in neutral markets. All round it appears that the railway companies in England charge about twice as much as the continental tariffs. In the face of all these disadvantages, it is satisfactory to learn that the statements with regard to the success achieved by continental firms is habitually exaggerated, and that England, as far as the metal trades are concerned, is not yet "going to the dogs," as pessimists would have us believe, though both Belgium and Germany undoubtedly take many orders which might have been executed in England, were we not so handicapped by external transport.

It is pointed out that Germany goes so far in encouraging its export trade as to have a double price list, charging considerably lower rates for goods destined to be sent abroad. Often this portion of its trade, it appears, is carried on at a loss, the manufacturers relying on the higher prices charged on goods for home consumption to recoup them. It is, of course, Germany's protective tariffs which permit it to charge higher rates on metals and machinery for its own use. After all, perhaps it is not an unmixed blessing to Great Britain that such should be the case, for heavy protective duties on this class of goods, at all events, have been proved to be the most efficient check on progress that a country can have. In England, where we have no protective duties which touch this industry, and where consequently the market is open not only to ourselves, but to Germans, Belgians, and Americans, our three principal competitors, English manufacturers are bound, in order to ensure a market for their goods both at home and abroad, to keep to the front in the way of quality, even when they cannot cut their prices down to those of continental firms; and it is more than probable that were Germany and the other countries to adopt Free Trade, the demand for British machines, large as it is, for use in those countries, would, in spite of their tariffs, be so greatly increased that the local manufacturers would have to bestir themselves to keep pace with us, and thus their competition in outside markets would be much more keenly felt by us than is at present the case. This matter of a double tariff for home and export has long been forcibly illustrated by American machines sent to Europe, as for years past machines manufactured in the United States, after a railway journey at both ends, and the sea voyage, and three loadings and dischargings, have been put on the market in England at a lower price than an American could purchase them for on the manufacturers' premises in his own country. With regard to raw material and coal, we are told, and can readily understand, that we are better off than our neighbours, both as regards quality and price, and all things being considered, it is just as well that such should be the case.

The moral to be drawn from this report is, undoubtedly, that while capital and labour are at continual war with each other in this country, they have overlooked, or at all events neglected, the fact that there are other causes besides the wages question which may tend to drive trade away from the country. The time of both masters and men would often have been much better employed in endeavouring in a peaceful manner to lessen these outside causes which tend to diminish our trade and cut down our profits to so great an extent that generosity on the part of masters in the way of increasing wages becomes an impossibility, even if they were willing to grant concessions. If, as is stated in the report, German and Belgian raw materials and manufactured iron and steel are taken by railway companies at half the price charged in Great Britain, there can be no conceivable reason why concessions should not be demanded from the companies, for our railway system is much more complete than any other in the world, and should be equally effective. It is true that railway dividends are small, but it is not clear that they would be reduced by a revision of tariffs, which would probably be followed by augmented receipts. If the employers' associations and the trade unions would for this purpose co-operate, they could together bring sufficient pressure to bear in the right quarters to effect a great change in transport tariffs. We are by no means advocates of the Government taking over, or having a great deal to do with, our railways and their management, and we consider that, if properly worked, the necessary concessions could be obtained without Government interference; but we would point out that the agitations which have taken place from time to time with regard to railway rates have, as a rule, been ineffective, and even disastrous, mainly because they have not been worked in a right way or by the right people. It will be remembered that when Government took the matter up, and instituted maximum rates for the different classes of goods, some few years ago, the result was the reverse of satisfactory. For the railway companies promptly adopted these maximum rates, which were in many cases considerably in excess of the prices they had hitherto charged, and the public have, as a rule, vainly endeavoured to get these rates reduced. It is, therefore, for master and man, who, after all, are the people who keep the railway companies going, to apply themselves in co-operation to effecting such reductions as will put their produce more on a par in price with that of their foreign competitors. With regard to quality, we have, as a rule, nothing to fear from German or any of our competitors in the engineering or iron industries up to the present.

ACCURACY.

OF the thousands of engineering firms all over the globe, the number which insist on a close approximation to accuracy of work might be expressed in two figures, yet the other firms which are content with less perfect work turn out machinery which performs its duties satisfactorily, and even in certain cases with great efficiency. It is not an uninteresting investigation, then, to look into the conditions which decide the particular degree of excellence which is most desirable in mechanical construction, and to attempt to arrive at a conclusion which may to some extent be capable of general application.

The question has to be viewed from two points, viz., that of the purchaser and that of the manufacturer; for though it may appear at first sight that the maker's most advantageous course is to provide an article which just meets the demand and no more, we think we shall be able to show that in a very great number of cases—we might almost say all cases—it is really to the manufacturer's advantage to maintain a higher standard of work than that upon which his customers insist. At present a higher price is demanded for a first-rate than for a second-rate machine, and this seems natural enough, but we fancy the time is not very far distant when the fact will be recognised that the higher class work, if conducted on the proper lines, is so little more expensive than the inferior quality that the difference should not be taken into consideration. However, the question for us now is to consider the matter as it stands from the two points of view indicated, and with the fact before us that two machines giving results for all practical purposes equally good, may differ from 25 to 30 per cent. in price—the "physical" difference being that the cheaper machine is fitted in the ordinary way, that is to say, no parts have been accurately gauged, but one part has been adjusted to the next, so that they fit with tolerable accuracy, and the whole when completed works with a near approach to smoothness, whilst the other has been made throughout with plus or minus allowances not exceeding a few thousandths of an inch. The most obvious factor in the decision of the purchaser must, of course, be the conditions under which the machinery is to work, and the length of life which is expected of it. No one would think of demanding in an excavator for a Panama Canal the beautiful accuracy and finish of a repeating rifle; not only because the class of work does not require it, but because the machine will only be required to operate for a comparatively short period, and will then disappear into that mysterious limbo whither goes most of the machinery of civil engineering. But when it is desired to keep a machine, be it engine or tool, and particularly the latter, running over an indefinitely extended period, and when repairs and renewals are bound to occur in the course of nature, the purchaser is undoubtedly wise in insisting on thoroughly good and accurate workmanship, for not only will a machine accurately fitted in the first place take much longer to get out of order, but repairs can be executed much more expeditiously, as spare parts ready to go directly into their places can be kept at hand or obtained on very short notice.

The question, then, for the purchaser is sufficiently simple, and in case he feels a difficulty in arriving at a decision from the consideration indicated above, the amount of money he is prepared to spend can generally be used to determine it. But, observe how much more complex is the matter as affecting the manufacturer. Putting aside for the moment the moral effect of the standard of work on his men, he has to take into account (1) The number of similar articles required; (2) the probability of future orders; (3) the cost of the necessary tools, both in outlay and in wear and tear discount; (4) the increase or decrease of highly-skilled labour; (5) the time of manufacture; (6) the increase of price of material, and several other items of a nature affecting his particular case, as shop space, standard of efficiency of his staff, &c. We have put the number of similar articles required and the probability of future orders in the first place, because, provided these be sufficiently high, they overweigh all other considerations. We are well aware that there are still many manufacturers turning out large quantities of machinery identical in all parts, who do not insist on a high standard of excellence. There can be little question that this is false economy. The necessary outlay in tools may mean drawing a considerable sum from the capital; but it will be returned in the increased facility of manufacture. Let us explain this more fully; and, for the sake of example, we will take the case of a large number of small steam engine cylinders all made from the same drawings. The quantity actually on order at any time, it should be observed, does not affect the question if the probability of future similar orders is considerable, or if the price for the first lot is sufficient to partly cover the expense of the tools. The maker who is not prepared to work accurately planes up one cylinder end, bolts the cylinder on to a face plate and bores it out with a simple tool. His lathe probably is not in the best condition, nor by the best maker. Consequently, his cylinder is a little taper and considerably elliptical, perhaps to the amount of several hundredths of an inch. His cylinder covers have in the meantime been turned, and the stuffing-box bored; he prefers probably to leave his piston until he can gauge the cylinder with an indifferent pair of callipers, and turn it to fit the smaller diameter. The holes for the cover studs have been marked off with compasses, or at best with a plate template, and drilled with a shaky drill through the cover. These holes are scribered through on to the cylinder ends, and the tapping holes drilled as accurately as a man can judge by his eye, concentrically with the clearance holes scribered on. They are then tapped by hand. Again, he chips out his ports to scriber lines, and makes his valve in the same way. It is unnecessary to go further. What is the result of all this ramshackle work? The cylinder has to be scraped out true, and the covers adjusted to the position in which the rods work through them best. Some studs are not vertical, and have to be knocked straight; others fit too tight or too loose in their holes; others are not in the right position, and the cover holes have to be filed out to suit. Tedious complications occur with the valve, and so on and so on. How much simpler are the same operations as performed by the best maker? The cylinder is held steady and two cuts taken through with long cutting tools gauged to a thousandth of an inch over the edges, and the ends faced from the boring bar. The stud holes are drilled from cast iron copies through holes bushed with hard steel, and are tapped and studded in a machine that ensures fit and verticality; the ports are milled out to a hard steel copy also. And so with the corresponding parts. What is the result? The engine can be put together, and work without hitch in a fifth the time the other takes. Through all the remaining details the same class of work is carried out. Fitting is reduced to a minimum; it is merely the putting together of parts which are gauge fits. But where fitting has to be done the same accuracy is observed; faces are scraped, not merely filed, and holes made gauge size and drilled through jigs, and all boring and turning done to fixed callipers or bar gauges. It is evident, therefore, that the superior maker can reduce slightly his number of highly skilled hands, though it must be borne in mind that a certain number taken from the fitting shop must be transferred to the tool shop and charged solely with the upkeep of all the accurate tools, templates, jigs, &c. On this point then he does not gain much if at all, and on the original outlay on tools he is considerably the loser. For really accurate work no feature is of nearly so great importance as the condition of the machine tools, and of all the tools, the lathes and milling machines require the greatest perfection and the tenderest care. No one who has not had practical experience of tools of different qualities can fully appreciate the vast difference there is between even a good tool and a perfect one. The manufacturer's outlay on tools must be very high, for he must have the very best tools, keep them in the best condition, and employ good workmen on them. We fancy this is one of the principal obstacles to great accuracy of work in already established firms. They are not prepared to go to the expense of large new plants, and they find they are totally unable to work to a fraction of a thousandth of an inch with their existing tools, so give up trying for "fit" at all, and are content if parts come together within a sixteenth or so. Considerable expense is also involved in the construction of jigs and copies; it not unfrequently occurs that a copy will cost more than the article it is to be used on, so that it is only in quantity that copies pay; but as we have pointed out above, provided the probability of orders is high, the outlay on chucks, jigs, &c., is well worth while, repaying itself over and over again in rapidity and ease of work. The last item we have specified is the increase in price of material, and it is taken on the basis that there must always be a certain percentage of rejection for faulty castings or forgings, and for mistakes in workmanship. If the limit of perfection is very narrow, as in Government specifications, this item may reach from 7 to 10 per cent., but should be a regularly decreasing factor as our knowledge of the whims and vagaries of materials become better understood and dealt with.

This seems a long bill of expenses against the manufacturer, and the only countercharge in his favour is the rate of turnout of work; yet so potent a factor is this that the highest class of work can be made to pay, and by the reputation which it makes, to increase the demand. The proof of this assertion is not far to seek, for the most prosperous firms in this country and abroad are those which have arrived at a high degree of accuracy. And it must be borne in mind that their success is largely due to the fact that by starting in the first place to turn out highly finished work, and having stood the expense of special tools and appliances, they have attracted to themselves extensive orders from all parts for similar articles, so that they have become firmly established in a speciality. No matter where we look, the same observation is true, that the most prosperous manufacturers are those who are able to create and meet a constant demand for some special form of machinery, be it big Corliss, or small high-speed engines, be it sewing machines or quick-fire guns. The power of turning out work rapidly is the cause of a great deal of specialised success, and as, other things being equal, the rate of output varies directly as the accuracy, we may say that in the long run a high degree of accuracy pays well.

But even where special tools cannot be afforded because the demand does not justify the expense, the proper use of standard plain and screw gauges and of rigid callipers should be insisted on, not only because it is expedient from a monetary point of view, but because it is desirable for the general welfare of the nation that its trades and professions should be kept at as high a standard as possible. Such a remote consideration, however, is not likely to affect many persons, and the best plea for good workmanship must be that inaccuracy is nearly as prolific as the greenfly and quite as blighting, whilst the path of accuracy, though it be strait at first, widens in the course of time and leads ultimately to success.

GREAT EASTERN RAILWAY WORKS.

ONE of the earliest of the railway reports to be issued for the past half-year is that of the Great Eastern Railway. The statement of accounts furnishes some facts that are of interest, and that indicate the progress of great works the company has had for some time in hand. In the past six months the Great Eastern has spent the sum of £163,199 on capital account. Out of this sum about £15,957 has been the cost of the purchases of land; and on the widening of lines £27,000 have been spent. The largest work of widening has been that between Bethnal Green and Hackney Downs, on which £8916 was spent in the last six months; and next to that, on the North Woolwich branch, £8643; whilst the remainder was expended on the Whitlingham to Wroxham, Stratford to Ilford, and Rochford to Prittlewell branches. On the electric light works at Liverpool-street, Bishopsgate, &c., the expenditure was £2478. There were additional works at various stations which cost £10,100, and those at Stratford took £9500. Other smaller sums bring up the total to over £103,000. The metropolitan lines have had a further sum of £19,139 spent on them, chiefly in construction of way and stations, &c. On working stock the half-year's expenditure was £39,729, out of which additional carriages took £17,774, and additional wagons £18,452. The capital expenditure on the Great Eastern is now falling off, as with an expenditure, as we have said, of £163,199 for the past half-year, the estimate for the present half-year is only £133,030, two-thirds of which are to be spent on the lines and works open for traffic, and nearly all the remainder is to be spent on additional working stock, so that, compared with the heavy expenditure of three or four years back, there is now a comparatively small sum being spent, and necessarily fewer works of moment are in course of execution. Many of the most important works are becoming productive, and to some of these the great improvement in the suburban traffic of the company is to be in considerable degree attributed, so that in the past six months the passengers on the line have averaged close upon 8,000,000 in each month, whilst the receipts have considerably increased both from ordinary passengers and season tickets. The Great Eastern will now reap the fruits of its recent extensions, and it is to be expected that increasing traffic, both passenger and merchandise, must pave the way for further extensions on a line which is now rapidly becoming one of the leading passenger lines of the country.

LITERATURE.

An Elementary Treatise on Heat and the Steam Engine By the Rev. ISAAC WARREN, M.A. Dublin: Hodges, Figgis and Co. London: Simpkin, Marshall and Co. 1895.

A LITTLE girl walking through a cemetery with her mother, after reading more or less closely a few score of epitaphs, is said to have asked where the bad people were buried? We never see the words "elementary treatise" without feeling disposed to ask where the non-elementary treatise is buried, and what it is like? In our younger days we spoke of treatises not elementary with bated breath, filled with awe. As we have grown older we have by degrees got to the Betsy Prigg frame of mind, and as that lady did not believe in Mrs. Harris, we are incredulous as to the existence of treatises non-elementary. To be more precise, and to apply what we have just written, we maintain that the book before us is very far from being "elementary." On the contrary, it is a very complete and advanced treatise on the steam engine and thermodynamics generally, and the author ought in subsequent editions to leave out the word "elementary" altogether.

Mr. Warren says in his preface that the object which he has "aimed at in this treatise has been to express in intelligible language the main facts of the Science of Heat, together with the Salient Principles which underlie the construction of the Modern Steam Engine." The author has done his work very well; that fact may be admitted at once; but whether the book will take the place of any one of a score of treatises on heat and the steam engine already in use, or at least on the shelves of libraries, is quite another matter. Knowing what we do, if we were buying text books again, we should buy this; but this is not tantamount to saying that those who have already other treatises ought to purchase this. Mr. Warren has succeeded in stating facts very clearly indeed, and the work ought to save much trouble to those who set about the arduous task of teaching themselves, and mathematical formulæ have been reduced to the smallest possible quantity, for which we offer our sincere thanks to the author. We are filled indeed with kindly thoughts concerning him, because he shows that thermodynamics are not after all creations of the mathematical brain, but a real science, the fundamental truths of which can be mastered by anyone possessing sense and fair reasoning power.

Mr. Warren has coined two new contractions, and writes about "Isots" and "Adiabs." These are not lingually æsthetic, but they will commend themselves to the undergraduate, and they lend completeness to the treatise. It may be taken for granted that no author who has any self respect will, in the present day, write a treatise on dynamics or thermodynamics without introducing some new names. We are glad to see that he quotes Lord Kelvin against those who hold that Rumford's experiment on boring cannon was conclusive against the materialistic theory of heat; whereas it was nothing of the kind.

We are not surprised to find that our author goes steadily over the old paths, and does not attempt to take away any of the stones which lie in the way of the thoughtful student. Nothing, perhaps, would be gained if he did under existing conditions. Examiners, for example, are not likely to expect that the student will see that the radiation of heat is an exception to the law that heat cannot pass from a cold body to one hotter than itself. It is open to question whether the production of heat by the resistance of an electric conductor is or is not an irreversible process. The two so-called "laws" of heat are not laws, but arbitrary definitions of certain conditions. The second law, as stated on page 215, is immensely defective. It runs thus: "It is impossible by the unaided action of natural processes to transform any part of the heat of a body into mechanical work, except by allowing heat to pass from that body into another of a lower temperature." Of course, every steam engine gives the lie to this proposition taken in one sense. It is quite different from Kelvin's statement of the second law. The statement on page 231, that the internal energy of a perfect gas depends only on its temperature, is open to question, seeing that hydrogen is raised instead of lowered in temperature by being passed through a porous plug, while the recorded particulars of Dr. Linde's experiments lead to the belief that the theory of gas energy needs some revision. Like almost every other writer on thermodynamics—except, perhaps, Mr. MacFarlane Gray—our author comes to grief over entropy. The following definition leaves the student just where he was:—"The entropy of a substance is a physical property of it which remains constant as long as heat does not enter or leave it *as heat*, *i.e.*, as long as the relation between its volume and pressure per unit area is graphically depicted by an adiabatic line." This reminds us of the celebrated definitions of the function of an archdeacon. It would be improved by the substitution of the word energy for the first "heat." In dealing with our old friend the Carnot cycle, Mr. Warren improves on Clerk-Maxwell, and uses four cylinders instead of three, or rather four positions or states instead of three. It is very difficult, however, to improve on Clerk-Maxwell on any point.

Of the section on the steam engine we can speak very favourably. The illustrations are all new and very effective. Figs. 92 and 95, in which we have combined the position of the crank pin, piston, and slide valve, are both ingenious and highly effective. The explanation of the theory of the injector is novel, although the theory explained is not.

Finally, we may say that while it would be quite easy to find defects in this book, it is far more easy to discover merit, and we take the line of least resistance. Mr. Warren has produced a very good little book, and we think the author deserves the grant which we believe has been made to him by the Board of Trinity College, Dublin, "In consideration of the services rendered to education by the production of the work." The book is a recognised college text-book, therefore, and bears on its title page the arms of the University.

Elements of Geometry. By GEORGE C. EDWARDS, Ph.B. Pages 293. Macmillan and Co. 1895. 7s. 6d.

THIS book is in reality a revision of Euclid's Elements; the cold, cut-and-dried method of the latter, as usually presented to English students, is avoided, and the subject is made interesting and practical. The whole treatment of the matter, and the numerous well-selected examples are justly calculated to appeal directly to the understanding, and thus to be retained in memory without effort, Algebraical expressions are frequently made use of, and aid considerably in simplifying the proof in certain cases; and all the definitions have, as the author states, been so framed that they will not need to be changed when the more advanced portions of the subject are attacked, or when other branches of mathematics are studied. The geometry of solids is dealt with in the same interesting manner, and includes the discussion of spherical arcs and triangles, surfaces and volumes of solids, and the book ends with an introductory chapter on conic sections. The book has been prepared especially for American readers, but, as it will certainly fill a hitherto unsatisfied want here as well as in America, we can heartily recommend it to the notice of English students.

Plane Geometrical Drawings. By ROBERT HARRIS. New Edition, revised and enlarged. London: George Bell and Sons. 1895. 3s. 6d.

THIS is no doubt a very useful book, and one that has been appreciated, or a new edition would not have been called for. It is intended, primarily, to meet the requirements of students preparing for the Woolwich or Sandhurst Army examinations. The problems on plane geometry are arranged and discussed in the usual orthodox manner which the teachers of our youth should know so well; there certainly are a few references to Euclid, but otherwise no elucidation is given as to the why or wherefore. In the graphic arithmetic the author embodies the co-ordinate equations of the line, circle, and parabola; this is a novelty in a book of this class, and should be welcomed. There are also a few useful pages on Graphic Statics and some capital collections of examples, most of which have been abstracted from examination papers. The figures are fair, but no particular care has been taken to have them accurately drawn—see, for instance, Figs. 129 and 138, plane geometry, and Figs. 2, 3, and 4, on cycloidal curves; we also notice that the author uses the term "director" of a parabola—page 108—instead of the classical expression directrix; this, however, may be simply a printer's error, not to be repeated.

SHORT NOTICES.

Tables and Diagrams of Switches and Crossings: A Handy Platelayers' Guide. By Thomas Summerson and Sons, Darlington. Third edition. 1895.—The fact that this little book has reached a third edition is sufficient evidence of its merits. The tables and diagrams are very complete and very clear, and cover gauges from 1ft. 6in. to 5ft. 6in. Simple and satisfactory instructions are given for setting out crossing angles. The type is large and the language simple, but the form of the book is more suitable for an engineer's office than for a foreman platelayer's pocket. It might be worth while to modify the next edition in this respect in a way which will no doubt be obvious to the authors.

The Shipbuilding and Marine Work of the Whole World, and Review of the Leading Trades in Scotland, &c., for 1895; *with Trade Prospects for* 1896. London: Effingham, Wilson, and Co., Royal Exchange; and Glasgow: Proprietors of *The Glasgow Herald.* Second year's issue.—Naval architects and marine engineers will find in this pamphlet a complete *résumé* of the world's progress in shipbuilding and marine engineering for the year 1895. The output is given of all the dockyards, and private yards abroad as well as at home, with plentiful detail and many valuable statistics. Other articles and tables, all on trade generally, such as coal, metals, timber, explosives, &c., more paticularly from a commercial point of view. The whole is in a handy form and is well printed. The publishers are to be congratulated on the second year's issue of so useful a compendium.

Ferguson's Ceylon Handbook and Directory, 1895-96. Kegan Paul, Trubner, and Co.; Street and Co.; John Haddon and Co. Bouverie House, Salisbury-square, E.C.—This latest issue of Messrs. Ferguson's well-known work surpasses in interest and completeness all those that have preceded it. Containing in all more than 1500 pages, more than half of these are filled with valuable and closely printed data and other information connected with the colony. The book is, in fact, a *vade mecum* for research, whether it be by the student of Ceylonese history, of the island topography, or of any other branch of local study. All will find in its pages, and in fullest detail, the information sought for. The work is throughout an admirable specimen of colonial typography, while the copious indexing leaves nothing to be desired by the searcher. We believe this important work of reference not to be even approached in scope and usefulness by any other Colony, save, perhaps, that of Victoria.

Annuaire pour l'an 1896. *Publié par le Bureau des Longitudes.* Small 8vo., pp. 894, with two maps. Paris: Gauthier, Villau and Son, 1896.—This well-known annual appears with the usual regularity at the New Year in the old familiar form of an almanac and ephemiris, accompanied by a large body of information on money, weights, measures, geographical and vital statistics, and physical and chemical contents for the principal natural substances; in fact, the useful knowledge in these fields which is susceptible of reduction to numerical tables. Apart from changes in the astronomical section, that on chronography has been enlarged by an article on the Chinese calendar. M. Moureaux gives a table of the magnetic constants determined by him in 1895, and which now amount to 644 stations, covering the whole of France, and in connection with this subject there is a notice in the literary supplement of a plan of simultaneous magnetic observations by eight groups of French naval officers on different foreign stations, which have been undertaken and in part completed for the purpose of improving the magnetic maps of the world. The newest data in solar and stellar spectroscopy are contained in M. Cornu's notes on these subjects, who also contributes the important literary articles, the first under the title of "Les Forces à Distance et ces Ondulations," being a popular sketch of the history of development in the undulatory theory from the time of Newton and Descartes to the present day, and the second on the optical work of Fresnel, both being papers of enduring value. M. Janssen gives an account of his third ascent of Mont Blanc, in September, 1895, when he stopped for fifty hours at the observatory on the summit, which has only slightly shifted in position during the past year. The air at the summit was extremely dry. With the temperature at the freezing point, and the dew point 32 degrees lower, the lines characteristic of water vapour in the solar spectrum had almost entirely disappeared, thus confirming M. Janssen in his opinion that such lines are entirely due to the terrestrial atmosphere. All the parts of a 12in. equatorial of special construction have been safely carried up to the observatory, but the construction has been deferred to the next season. The biographical notices at the end contain an account of the life and work of Rear-Admiral Fleuriais, a distinguished officer both in the military and hydrographic branches of the service, who died very suddenly in June last while superintending the equipment of the North Atlantic Squadron, which he was appointed to command. He was elected to the Board on the death of Admiral Mouchez in 1893, and contributed a charming article on the history of the mariner's compass to the *Annuaire* for 1894. Another notable loss is M. Emile Brunner, the famous astronomical instrument maker, whose decease leaves the "Artist" class of members unrepresented at the Board.

BOOKS RECEIVED.

A Text-book of Gas Manufacture for Students. By John Hornby, F.I.E. London: George Bell and Sons. 1896. Price 5s.

Forth and Clyde Ship Canal in Relation to the Development of Cemmerce. By J. Law Crawford. Glasgow and London: MacLaren and Sons.

Shipbuilding and Marine Work of the Whole World, and Review of Leading Trades for 1895. London: Effingham, Wilson, and Co. Price 1s. Paper.

A Treatise on Mine Surveying. By Bennett H. Brough. Fifth edition, revised. With numerous diagrams. London: Charles Griffin and Co., Ld. 1896. Price 7s. 6d.

Refrigerating and Ice-making Machinery. A Descriptive Treatise for the use of Persons employing Refrigerating and Ice-making Installations and Others. By A. J. Wallis-Tayler, C.E. London: Crosby Lockwood and Son. 1896.

A Text-book of Marine Engineering for the use of Naval Officers, Marine Engineers, and Students of Marine and Mechanical Engineering. By A. E. Tompkins, Engineer, Royal Navy. With 134 illustrations. Portsmouth: J. Griffin and Co. 1896.

Chemistry for Engineers and Manufacturers. A Practical Text-book. By Bertram Blount and A. G. Bloxam. With illustrations. Volume I.: Chemistry of Engineering, Building, and Metallurgy. London: Charles Griffin and Co., Ld. 1896. Price 10s. 6d.

ALMANACKS AND CALENDARS FOR 1896.

MESSRS. J. ROGERSON AND CO., of the Stanners Close Steel Works, Walsingham, Darlington, send a monthly sheet almanack with the sheets arranged to be turned over and kept for reference. They have good plain figures, and the background is illustrated by engravings of the great variety of steel castings made by the firm from small to very large.

We have received from Messrs. Owen, Brazil, and Co., of the Vulcan Ironworks, Avonside, Bristol, a nice table calendar, with removable and renewable monthly cards printed with clear figures.

Messrs. Ernest Scott and Mountain send a delicately coloured calendar, with monthly tear-off sheets, the background representing some of the firm's specialities in electrical mechanical engineering.

Messrs. Samuelson and Co., of Banbury, send a calendar.

The Columbia Bicycle Company, of Hartford, Connecticut, send a daily tear-off calendar on a metal base. On each day is a suitable remark or *bon mot* relating to cycling or roads and highways, and riding, and a clear space is left for notes concerning coming events or appointments, &c., and as each sheet is held only at one end these sheets are conveniently used for the purpose. The moon's phases are given, but the time for lighting lamps is not, so we may assume the arm of the law is not free in America to stop a cyclist having no light.

THE SHIPBUILDING DISPUTE.

WE are happy to say that it has been officially announced by the secretary of the Amalgamated Society of Engineers that the dispute on the Clyde and in Belfast has been settled. On the Clyde things are quite clear. Belfast was the difficulty, and concerning matters there it was stated yesterday morning that a meeting of the district committee of the Belfast engineers was held at the Engineers' Hall on Wednesday night, and was addressed by Mr. M'Dowell. It is understood that Mr. M'Dowell won over a majority of the committee to the course suggested by the executive. Subsequently Mr. M'Dowell stated, in answer to inquiries, that no ballot meeting of the engineers would take place, but a mass meeting of the men would be held to-day. Mr. M'Dowell intimated that matters stood fairly well for a prompt settlement of the dispute.

REGENERATIVE COLD.

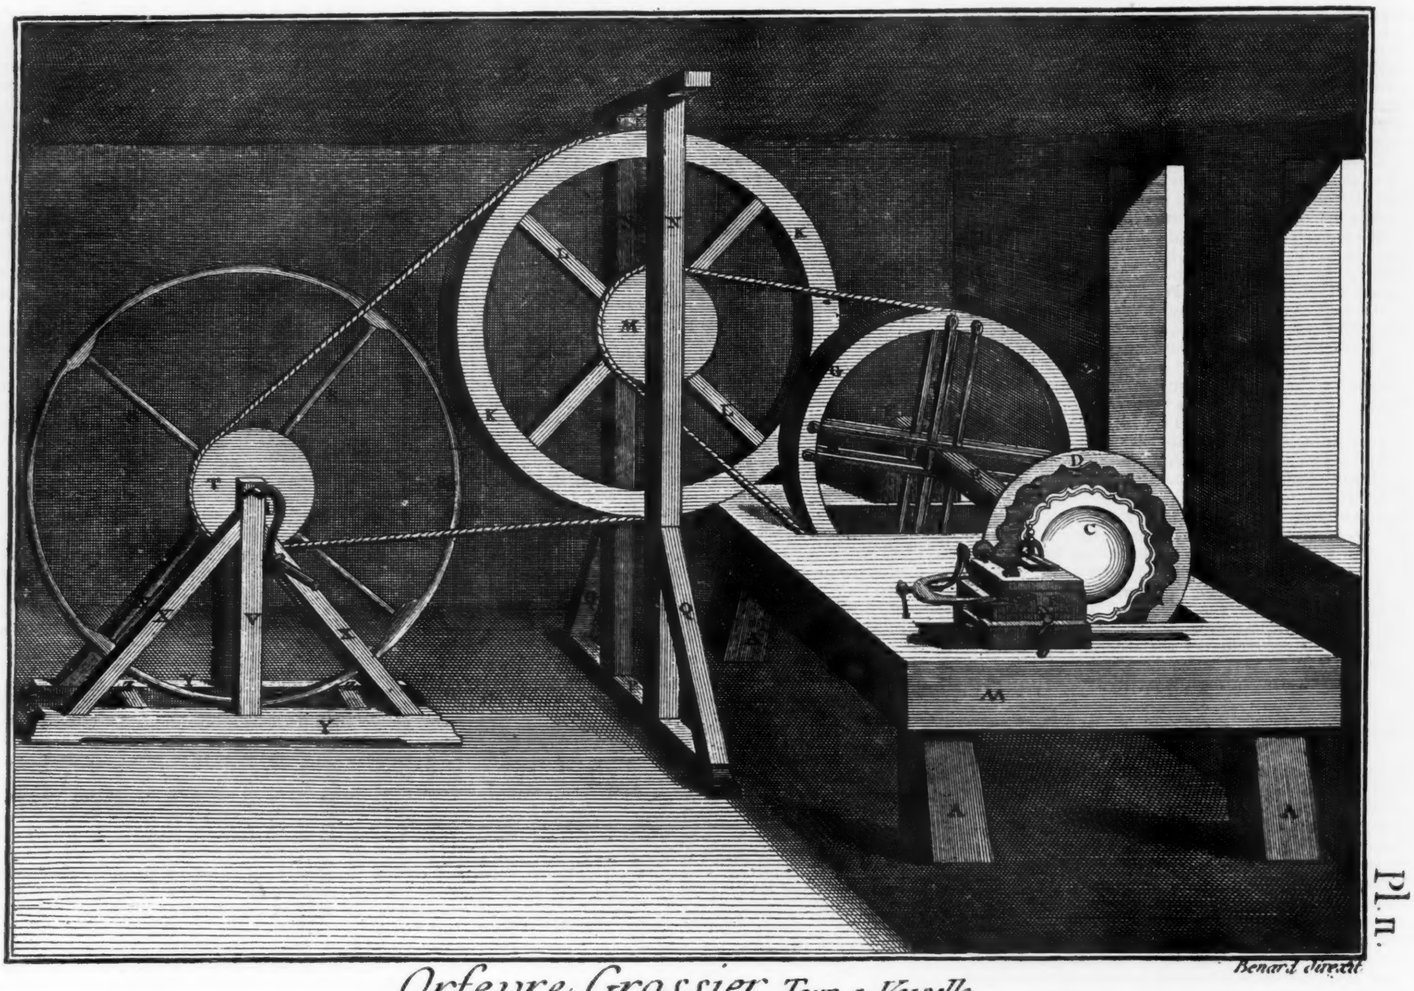
IN our impression for October the 4th we gave a description, condensed from a paper by Herr Schrötter, of the new Linde method of producing cold. We use the word "new," because Dr. Linde has long been known as the discoverer of several admirable methods of constructing refrigerating plant. For reasons not at first sight very obvious, a certain amount of uncertainty and confusion has invested this latest device, and if rumour is to be trusted, some questions connected with it will have to be settled in the law courts. With this matter, however, we have nothing to do. The process is remarkable in many ways. It is remarkable for the fact that it was not used long since; it is remarkable that its nature is not fully understood; and it is doubly remarkable that the facts connected with it have not long since been published. The theory of the Linde process, as we shall call it, admits of being simply stated; we shall so state it, and then deal with the extraneous matters with which the theory has been surrounded.

When a gas is compressed in a non-conducting cylinder its temperature is raised, and the foot-pounds of work done in compressing it are represented by the number of degrees of rise in temperature multiplied by the specific heat of the gas and by 772. When the gas is allowed to expand to its original volume it will fall to its original temperature, provided it is a perfect gas, and will do as much work in expanding as was done upon it during the period of compression. If the gas is not perfect there will be a small loss, and the gas will be a little colder after the operation than it was before. What becomes of the lost energy no one knows. If the gas is perfect there is no loss; if the gas is hydrogen there is a small gain; the temperature being greater after than before compression and expansion. Various explanations have been advanced; we need not concern ourselves with them. In any case the amount of loss or gain is very small. If a gas expands without doing work there is no change of temperature. But there is no known direct means of expanding a gas without overcoming a resistance, and so we have to get at the facts in a roundabout way. Joule took two iron bottles; into one he compressed air to a very heavy pressure, in the other was a vacuum. He coupled the bottles by a pipe and a stop cock, and he put them both in a tank of water at 60 deg. When the temperature was uniform he opened the cock and let the air flow from one bottle to the other. When the temperatures had adjusted themselves it was found that the thermometer stood at very nearly 60 deg.; but during the passage of the air from one bottle to the other the temperature fell in the delivery bottle. Every student of thermodynamics knows why, as far as anyone can be said to know at all. Now, we have here the elements of the cold air refrigerating machine. If it was possible to make a room, compress air into it, and then let the air escape, very intense cold might be produced in the room. This, however, is not a feasible way of working, and so a different method is used. But we may say here that cold air machines have been constructed on the mistaken idea that the air discharged after compression must be cold; the idea being that the receiver bottle in Joule's experiment would be cold, because the delivery one was. Such schemes have, of course, ended in failure. The cold air machine as produced by Giffard, Kirk, Hall, and others works in a different way. Air at, say, 60 deg. is compressed; its temperature is raised during compression according to well-known laws. Thus, by compressing it into one-third of its original space, its temperature would be raised to about 245 deg. Fah. While the air was at 60 deg. no heat could be got out of it by water at 60 deg., but being now raised in temperature, heat can be extracted by passing the air through a surface condenser. We now have the air at a considerable pressure, and at, say, 70 deg. The air is now allowed to expand, and do work in expanding, by driving a piston which helps the compressing engine, and the exhaust air, which has now lost all the heat given up in the condenser, besides that converted into work during expansion, is delivered into the cold room, where the meat to be chilled is kept. So far we have had no occasion to mention Dr. Linde's apparatus, or Regenerative Cold. What we have said was necessary to clear the ground, and make what follows intelligible.

We have said that the air was taken into the refrigerating machine at 60 deg. Now let us suppose that we want to produce a much more intense cold than anything to be had under ordinary conditions. It is obvious that much would be gained in this direction if we supplied the compressing pumps with air drawn from the cold room at, say, – 15 deg. instead of at 60 deg. The late Professor Balfour Stewart, talking of apparatus for producing extreme cold, said that the best effects could be got near the North Pole, where mercury was a solid and strong rum resembled honey in consistency. Again, if we used a third machine and supplied its pumps with air at, say—80 deg., furnished by machine No. 2, we should get a further fall in temperature. We must not forget, however, that apparently water could not be used as the cooling medium, because it would be converted into ice. As a matter of fact, in small apparatus water cannot be so used, and carbonic anhydride liquefied, or some other volatile fluid, is used to carry off the heat. But on a large scale water can be used, and is used by Dr. Linde. No matter how cold air is, it can have its temperature raised to any point we please by compressing it sufficiently. If our readers will now turn to THE ENGINEER for October 4th, they will find an illustration of the apparatus used by Dr. Linde. The compressed air is delivered through a small nozzle above that part of the apparatus in which liquefaction takes place. Now, it is about the functions of this nozzle that confusion exists. To judge from Professor Schrötter, without the nozzle there could be no liquid air. He seems to hold the view that the cooling is a result of what has been erroneously called "Joule's effect." We have said that when an

AN EARLY COPYING LATHE

(*For description see page 93*)



Orfevre Grossier, Tour a Vaiselle.

imperfect gas is passed through a porous plug or other small aperture it is cooled. But, as a matter of fact, the apparatus would work with a perfect gas, and is partly independent of Joule's effect. No doubt that effect helps, but it is in no way essential. Let us suppose that a stated quantity of air, say 100 lb., was put into an apparatus surrounded with air at 60 deg. Now, so long as that air was compressed and expanded wholly within the apparatus, and did no external work, there could be no loss of energy unless the temperature was raised, so that heat could escape from the apparatus, or unless it did work on, say, a piston. There is no theory which will lead to the belief that by merely passing the same air over and over again through a small orifice, the air would ultimately lose so much energy that it would liquefy, save one. When steam is permitted to escape through a contracted orifice electricity is produced, and the current carries away some energy. If the same action takes place with compressed air, then energy would be lost and cooling would be accounted for. To assume that the energy in the air would gradually disappear from an apparatus doing no external work, and losing no heat by radiation or conduction, is simply to assume that energy would be annihilated. What does happen is this: The air, cooled by expanding against a resistance, passes away to the compressing pump. In doing so it has its temperature raised by the air flowing down to the nozzle from the cooler. The exchange of heat goes on rapidly through the thin copper pipe, and so by the time the air has reached the compressing pump its temperature has been raised to probably 40 deg., or even more. In the compressing pump, it is, we believe, reduced in volume to one third, not one half as stated by Herr Schrötter. Now the coefficient of temperature for a threefold compression is 1·375. The total heat of air at 40 is $40 + 461 = 501$, and $501 \times 1{\cdot}375 = 688{\cdot}87$. Deducting 461, we have 227·87 deg. Fah. as the temperature at which the air is delivered to the cooler in which water is circulating at 60 deg. It will be seen that it is on the cooler that the whole process depends for success. Energy has to be got out of the air, and the only place where it can be got out is in the cooler. Taking it for granted that no more energy leaves the apparatus through the cooler than the compressing pump engine puts into it, we come to a very important feature of the apparatus. We have said that, in the case of the two Joule's bottles, one was cooled while the other was heated. Now, the speciality of Dr. Linde's apparatus lies in the circumstance that he can have in the same apparatus, and in close proximity to each other, very different temperatures. It will be seen that the temperature of the air leaving the cooler must be over 60 deg., while that of the air which expands in passing through the nozzle is probably —194 deg. It is almost certain that the required result could not be got were it not that the temperature of the air after it has left the cooler is still further reduced by the application of the principle of Regenerative Cold, the effect of which is to localise temperatures. Let us suppose that we have two long pipes, one inside the other, and that we pass two streams of air through these pipes, one of these having a very low and the other a very high temperature, in opposite directions. Let us call these A and B; a transfer of heat will take place so long as there is a difference of temperature, and as A, the hot air, advances and cools, it continually meets with air a little colder still. In the same way, as the cold air advances and becomes heated, it encounters inch after inch air a little hotter than itself. So, in the Linde apparatus, the air coming from the cooler continually meets with colder and colder air, the result being, as we have shown, that the temperature of the air going to the compressing pump is raised, while that going to the expansion nozzle is lowered.

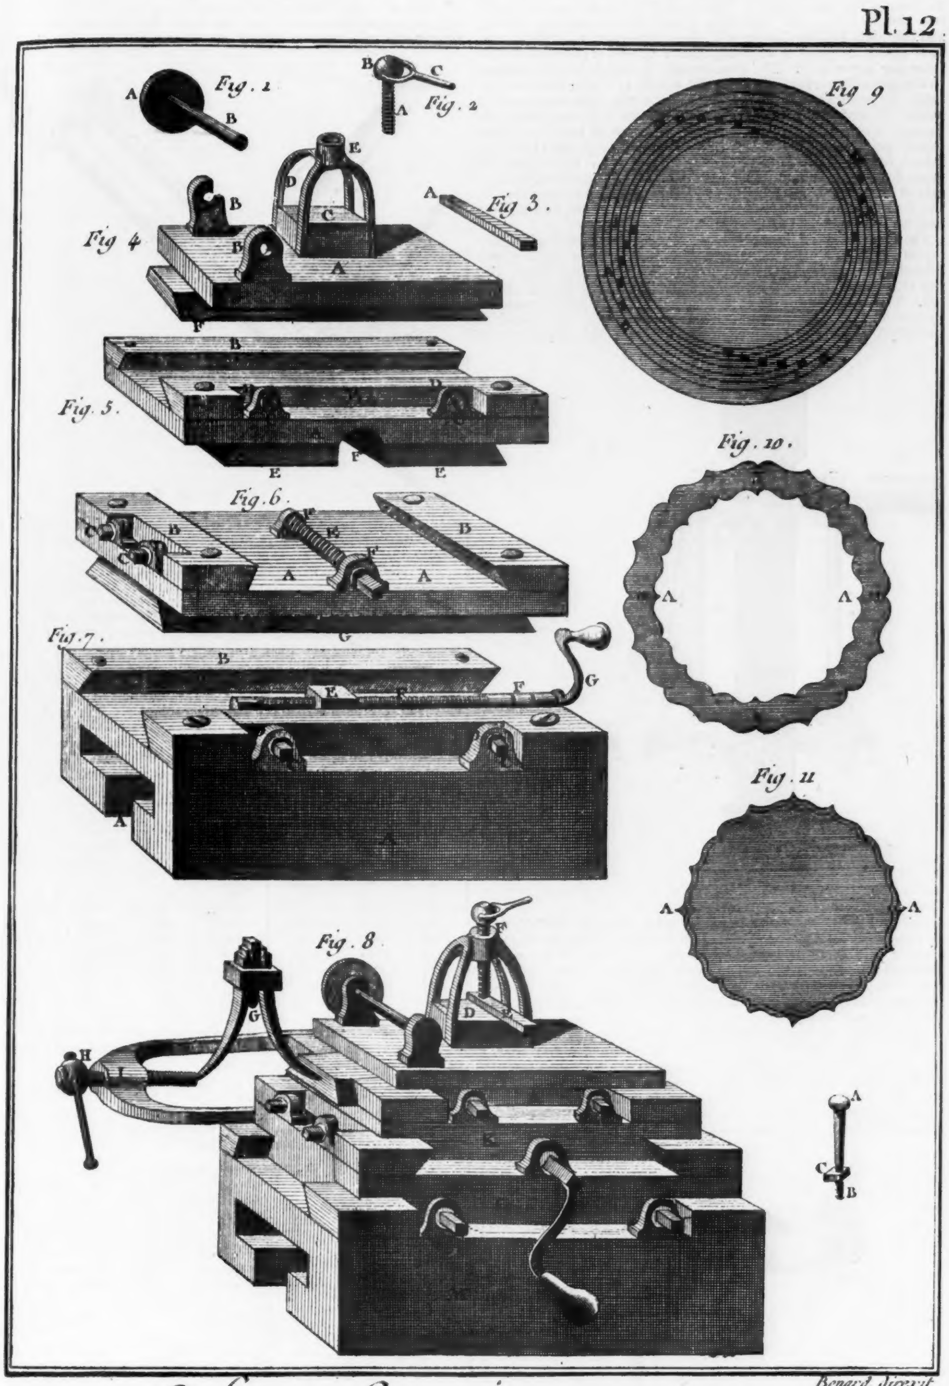
We have used the words "Regenerative Cold," but they are not ours but Professor Dewar's. We have now before us the text of the paper which he read on the 19th December last. We quote the following passage:—"In all continuously working circuits of liquid gases used in refrigerating apparatus the regenerative principle applied to cold first introduced by Siemens, in 1857, and subsequently employed in the freezing machines of Kirk, Coleman, Solvay, Linde, and others, has been adopted." Professor Dewar does not mean that Siemens invented the application of the principle of regeneration to the production of low temperatures, but only that he invented the principle of regeneration; but this is not the fact. In Rankine on "The Steam Engine," page 344, we have under the head "Heat Economiser or Regenerator":—"This difficulty is almost entirely avoided by the following process for producing alternate elevation and depression of temperature with a small expenditure of heat, invented about the year 1816 by the Rev. Dr. Robert Stirling, and subsequently improved and modified by Mr. James Stirling, Captain Ericsson, Mr. Siemens, and others." Rankine then goes on to describe the regenerator. But, as a matter of fact, the method adopted by Linde has next to nothing in common with either Stirling or Siemens. They turned hot air on to wire gratings or bricks, which were raised in temperature by the waste heat. Then a fresh supply of cold air was turned into the heated chamber and warmed. The process is intermittent; the heated bricks in the Siemens regenerator, the hot-plates in Stirling's air engine, or the wire gauze used by Ericsson, acting alternately as recipients and deliverers of heat. In this way Siemens produced the highest temperatures on a large scale known. But it is clear that there is nothing in common between this system and that adopted in the Linde apparatus.

We have already said that the cooling effect which is produced by passing the air through a contracted orifice is very small. We may quote here Professor Dewar as to the reason why the Linde nozzle is more effective than that used by Pictet. "The stopcock that Pictet employed to draw off liquid and produce sudden expansion was in his apparatus placed outside the refrigerator proper, but it is now placed inside, so as to be kept cool by the gases undergoing expansion. This improvement was introduced along with that of isolating the liquid gases by surrounding them with their own vapour in the apparatus made wholly of copper. It is interesting to note in passing that Pictet could get no liquid oxygen jet below 270 atmospheres. This was due to his stop-cock being massive and outside the refrigerator." One point remains for consideration, that is what is known as the cumulative effect. These words are calculated to convey a wrong impression. There is no cumulative effect. The energy contained in the air to be liquefied has to be got out of it, and the only door of exit is the cooler. Work is continuously being done on the air by the circulating engine, which has to raise the pressure from about 350 lb. to about 1000 lb. on the square inch, and the resulting heat must be disposed of. Cold is produced because the air is compressed isothermally and expanded adiabatically. The nozzle is not essential, as would appear from Herr Schrötter's paper, but it is convenient. A fall of twenty atmospheres in pressure would by nozzle action alone only reduce the temperature by about 5 deg. or 6 deg. C. In a word, an ordinary cold air machine, such as Giffard's or Hall's, might be made to produce liquid air by working it at very high pressure, but for the difficulties of lubrication. The fact remains that Dr. Linde has produced an exceedingly beautiful apparatus of extreme simplicity, in the working of which phenomena are manifested of singular interest; but it seems to be clear that the first description of it which appeared in this country, that by Herr Schrötter, conveyed a somewhat erroneous impression, the work of adiabatic expansion being underrated, and that of the nozzle being unduly magnified.

X.

THE record for rapid erection of tall steel buildings has, according to *Engineering News*, been broken by the erection of thirteen and a-half storeys of the ironwork for the Fisher Building, in Chicago, in fourteen days. Previous to this performance, the erection of nine storeys of the Reliance Building, in Chicago, in two weeks was the best record. Both of these buildings were illustrated and described in our issue of October 17th. The Fisher Building is eighteen stories, or 235ft. high, and covers a ground area of 70ft. by 100ft. Work was begun excavating for the foundations July 3rd, and by the last of August they were ready for the ironwork. The first iron arrived October 12th, and work was begun, but it was not until October 19th that the iron could be had as fast as wanted. From October 19th to November 2nd, fourteen days, thirteen and a-half storeys were erected. On November 14th the eighteenth storey was finished, and on November 17th the attic and roof had been completed. From October 12th to November 17th inclusive, there were thirty-seven days, on six of which no work was done, which makes the time thirty-one days for erecting the whole framework for eighteen storeys, attic, and roof. Work is in progress upon the terra-cotta covering, and by December 1st it was expected that the building would be entirely closed in.

AN EARLY COPYING LATHE



Benard Direxit

Orfevre Grossier, Tour à Vaisselle

AN EARLY COPYING LATHE WITH SLIDE REST.

On another page and above we reproduce from the *Encyclopédie des Arts et Metiers*, published at Paris in 1771, two plates representing a curious and early form of the copying lathe adapted for forming the scalloped edge and ornamentation of silver dishes. The text gives no account of the origin of the machine, nor does it mention the name of the inventor, the only particulars furnished consisting of a detailed and minute account of the various parts. The mode of action is, however, perfectly clear. The pattern is fixed upon the face plate D, to which the dish C is also attached. The tool is fixed in a veritable slide rest, identical in its principal details with the slide rest of the present day, and this constitutes another interesting feature of this machine. It is the earliest instance of the appliance which we have met with. As the pattern revolves it causes the rest and tool to move backwards and forwards, the tool being kept to its work by the spring, shown on a larger scale in Fig. 8. One would like very much to know whether this was merely a design or whether the drawing was made from an actual machine.

It will be noticed that the machine as represented is incapable of producing the particular form of scalloped edge depicted, because the friction roller which bears against the pattern could not enter the deep angles of the pattern. The edge actually produced would be of a wavy character, consisting of a series of easy curves. This is, however, in all probability an error of the draughtsman, who thought that an edge with sharp angles would look better. The plates are reproduced not from the original edition of the *Encyclopédie*, but from a subsequent edition in quarto, published in 1781 under the title of *Encyclopédie Methodique*. In almost every detail the plates are identical, though on a somewhat reduced scale. The engravings in the folio edition of 1771 show a wavy edge of easy curves such as a friction roller could readily follow. This explanation seems to be necessary to account for an obvious imperfection in the machine as shown. The plates do not, as might be supposed, belong to the article "Tour" (lathe), but form a portion of the illustrations of "Orfévre Grossier" (gold and silversmith). We have no intention of entering into the vexed question of the invention of the slide rest, but here we undoubtedly have a particular form of slide rest, though not applied to the uses to which it was put by Bramah and Maudslay at a later period. There was an article on this subject on page 391 of the last volume of THE ENGINEER.

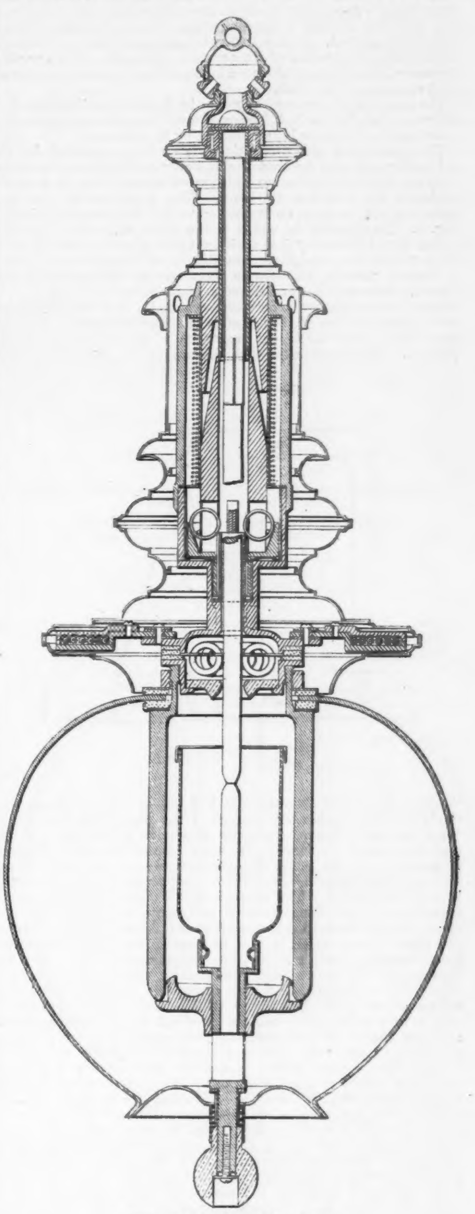
THE JANDUS ARC LAMP.

It is well known that the arc lamp is the most economical instrument for utilising the electric current in the production of light. The drawbacks to the lamp and its defects are equally well known.

Mr. Jandus, an American electrician, has devoted many years to the production of an arc lamp which will be free from that defect, and will be suitable for internal lighting. To this end it is necessary first that the current should be small; secondly, that the carbons should last a long time; and lastly, that the lamps should be simple. We illustrate the lamps as made by Messrs. Johnson and Phillips, of Charlton.

The carbons are carefully selected and of the best quality, and they are "burned" in an atmosphere, self-produced, of carbonic acid. The result is that, instead of wasting at the rate of 1½in. to 2in. per hour for the positive and half that rate for the negative carbon, a positive carbon may last a week, no true combustion taking place at all. It will be seen from our engraving that the carbons are enclosed in a glass jar, open-mouthed, bottomless, and inverted. The top carbon passes, a slack fit, through a hole in a light brass plate, which lies on the bottom of the jar, or rather, as the jar is inverted, on its upper edges. The jar soon becomes filled with carbonic acid, which being heavy, does not tend to escape. But as a further precaution, the outer globe is fitted air-tight at top as shown, at the bottom it is carried on a spun dish plate of brass. The result is that, as we have said, the carbons are surrounded by an atmosphere containing little or no free oxygen, and, as a consequence, they do not burn away.

The feeding mechanism of such a lamp escapes many troubles; under ordinary conditions it is necessary to make the feed as nearly continuous as possible to avoid blinking. In the early days of arc lighting lamps were used which struck the arc by drawing the carbons apart; the light lasted until the carbons had wasted to such an extent that the current could no longer jump across; then the carbons fell together. The current was re-established, the arc re-opened, and things went on as before for five or ten minutes, when the process was repeated. Quick as the fall of the carbon and its rise was, there was a blink quite sensible and annoying to the eye. Now in the Jandus lamp, seeing that the blink does not take place oftener than once in an hour or two, it is of no consequence, and the arc is struck by a coned electro-magnet seen in section in the top of the lamp, in which is a coned armature. The lamps are used in multiple arc, a small resistance being used in the ordinary way to steady them, and consequently no shunt coil is needed. The clutch by which the armature grips the carbon carrier is very ingenious. It will be seen just at the base of the armature, and consists of four milled edge rings, lying inside a conical cup. When the cup rises the rings are forced inward against the carbon holder rod, and gripping it, raises it. It would be very difficult to make the action, which is extremely simple when seen, intelligible to those who have not seen it. In the lower part just above the globe will be seen a number of rings, these take the current into the top carbon. The rings are threaded into notches in the edge of a thin brass diaphragm plate, and they act as guides to the carbon holder. Some of them are certain to be in contact somewhere with the plate, and to carry the current. They take in a very elegant way the place of brushes or springs, and work without friction.



THE JANDUS ARC LAMP

The details of the lamp have been very carefully thought out. The current used is very small, three to five ampères for indoor work, and, hanging in a hall or dining-room, the light, in its silence and steadiness, resembles that of the old-fashioned French "Moderator" more than any other, being quite soft, perfectly silent, and free from sputter or hiss. At long intervals there is a blink, but it is not easy to detect it unless it is watched for. Mr. Jandus has, we think, solved the problem of applying the arc to internal lighting, and we have no hesitation in saying that it is the best lamp of its kind that has yet been produced.

THE INSTITUTION OF CIVIL ENGINEERS: NEWCASTLE-UPON-TYNE ASSOCIATION OF STUDENTS.—The third general meeting of the present session was held in the Durham College of Science, Newcastle-on-Tyne, on Wednesday, 15th January, when Mr. J. D. Wardale, M. Inst. C.E., was in the chair. Mr. C. G. Henzell, Assoc. M. Inst. C.E., read a paper on the Rede pipe line of the Newcastle and Gateshead Water Company.

ON MEASUREMENTS OF SMALL STRAINS IN THE TESTING OF MATERIALS AND STRUCTURES.[*]

By J. A. EWING, M.A., F.R.S., Professor of Mechanism and Applied Mechanics in the University of Cambridge.

MANY forms of "extensometer" have been devised for measuring the small strains of extension or compression which precede yielding in materials subjected to stress by direct pull or push. Such instruments are employed, in the testing of metals, for determining Young's modulus and for observing the behaviour of the material as the limit of elasticity is passed. Apparatus of the same general kind has also been applied to examine the strains produced in the members of bridges and other structures by the application of load to the structure as a whole; the amount of stress in any member being in that case inferred from observation of the strain. Professor Unwin, who has himself designed more than one form of extensometer, has described in his work on the "Testing of Materials of Construction" a number of instruments of this class, and has pointed out that a first condition of accuracy is that the measurements of extension be made on both of two sides of the piece, in such a way that a mean is obtained representing the extension of a central line. In practice, a rod always bends more or less on being pulled. Even when the rod is initially straight the pull is rarely, if ever, so symmetrically applied or the elasticity so uniform as to make the extension equal at all parts of the section. Hence, to avoid errors which would be great relative to the quantity under examination, the extensometer must be arranged in such a fashion that its indications depend only on the change of distance between two points on the axis of the rod, and are independent of those inequalities which are found to exist in the strains as measured on the surface. The condition is met either by taking two separate observations of the strain on two sides of the rod and averaging the two, or by making the extensometer itself indicate a mean strain. Bauschinger's apparatus, in which two mirrors are used to indicate separately the strains on opposite sides of the rod, is an example of the first method. Professor Unwin's extensometer, in which the rod is grasped by a pair of clips at the extremities of two parallel diameters, the change of distance between the clips being measured, is an example of the other.

The object of the present paper is to describe an instrument of the same class, but embodying some novel features, and to mention a few results that have been obtained by its means.

The instrument is self-contained, is entirely supported by the rod under test, and touches the rod only at the points where the clips are attached—a feature which is of advantage in view of the tendency the rod has to bend. The principle of the construction will be seen on referring to the diagrammatic sketch, Fig. 1. To the rod A, which is the piece under test, the two pieces B and C are attached each by a pair of set-screws. Each of these pieces has, separately, one degree of freedom with respect to the rod, namely, freedom to rotate about the axis of its set-screws. Hence, B has two degrees of freedom relatively to C, so long as the two are not otherwise connected. But the piece B has fixed to it an arm B′, which ends in a rounded point P, and this point gears in a V-slot cut transversely across the end of the piece C. The contact of P with the two sides of this slot removes the two degrees of freedom which B would otherwise have relatively to C, and makes the position of the pieces definite. Then, when the rod extends, the point P acts as a fulcrum, and the opposite end of C, namely, Q, moves down through a distance proportional to the mean displacement of the two pairs of set screws. The displacement of Q is a multiple of the strain, in the ratio of P Q to O Q. This displacement is measured by means of a microscope, which hangs from B and sights an object at Q. The strains to be observed are so small that it is easy, without making the piece C inconveniently long, to prevent its angular movement from becoming sufficient to prove troublesome or to affect the accuracy of the indications. The arm B′, which carries the point P, must be so attached to B that, as regards oscillation about the set-screws of B, the two pieces B and B′ move as a rigid whole. But B′ may be flexible in the direction which would give P motion at right angles to the plane of the paper, and by giving it flexibility of this kind—while preserving its rigidity as regards motion in the plane of the paper—the point P may be made to gear in a hole instead of a slot in C. There is a practical advantage in doing this, for if P gears in a slot any unequal extension of the front and back of the specimen makes P work along the slot, and it is difficult to secure that no error will result in consequence of the slot not being perfectly parallel to the axes of the set-screws. This consideration has led the author to adopt the plan of putting a transverse joint between the pieces B and B′, with the object of giving P freedom to adjust itself to a hole—instead of a slot—in C, by movement about this joint in a direction perpendicular to the plane of the sketch. Incidently, such a joint has the further advantage that it allows the whole apparatus to be more conveniently and quickly applied to the rod under examination.

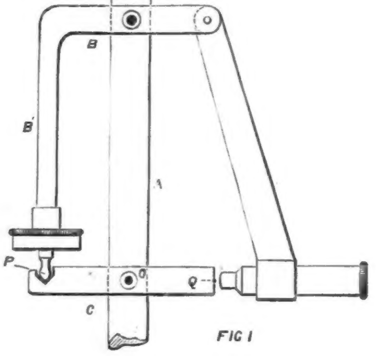


FIG 1

The displacement of Q due to the strain is measured by means of a micrometer in the eye-piece of the microscope. A micrometer scale engraved on glass is convenient for the purpose, and by estimating tenths of a division on such a scale readings are readily taken which correspond to one fifty-thousandth of an inch of extension on the part of the specimen, with an objective which allows the whole of the elastic extension to occur without displacing Q beyond the field of view.

There is a fine screw with a divided head between B′ and the point P. This serves to bring Q into a convenient position for sighting, and also to determine what is the absolute amount of extension corresponding to a division of the eye-piece scale. Should a strain occur exceeding the range of the eye-piece scale, Q is brought back into the field of view by turning P through a distance which is observed by means of a divided head.

Fig. 2 is a view of the complete instrument, taken from a photograph. The clips B and C are in this instance set at 8in. apart, and B is jointed to B′ by a transverse joint, giving P freedom to accommodate itself to a hole in C. The joint between B and B′ consists of two upright pins fixed in B, one of which presses up into a hole and the other into a slot in B′, the line of this hole and slot being perpendicular to the axis of the set-screws by which the clip is attached to the rod under test. Hence, so far as movement about the axis of the set-screws is concerned, B and B′ act as a rigid whole. This movement is prevented by the gearing of P in the hole in the lower clip C. The piece B′ is a frame consisting of two parallel steel rods united by a cross-bar at top and bottom, and carrying, besides the screw P, the microscope, which is hinged to B′ about the point E vertically above Q, and is provided with a focussing screw at F. The counterpoise D, which is also attached to the piece B′, serves to balance the weight of the microscope and make the pressure vertical between P and the hole into which it gears. There is a supplementary counterpoise D′ for adjusting the balance about the axis of the joint between B and B′. These counterpoises are adjusted until when the heavy end Q of C is raised, so that P ceases to be in gear with C, P has no tendency to move in any direction. The excess of weight on the right hand side of C suffices to produce the requisite pressure at the point P. The frame B B′ with the microscope may be lifted off, leaving only the two clips attached to the rod.

The object sighted is one side of a wire stretched horizontally across a hole in a plate at Q, and illuminated by a small mirror behind. The distances O P and O Q are in this instance equal, with the effect that the movement of Q is double the extension of the rod. The eye-piece scale and the length of the microscope are chosen so that the numbers read on the scale correspond to one fifty-thousandth of an inch of extension. This adjustment is tested by turning the screw P, which has a pitch of one-fiftieth of an inch, through one revolution, and observing that the displacement of Q is 500 units of the eye-piece scale. In the instrument illustrated in Fig. 2 the whole scale comprises 1400 units, and calibration tests show that throughout the middle 1200 of them the proportionality of the scale readings with the real movements of Q is practically perfect.

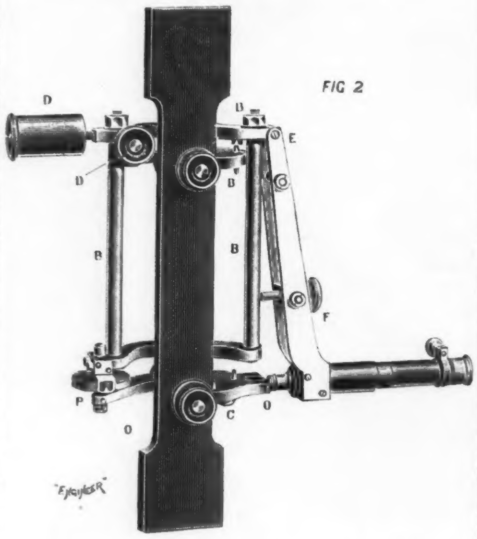

FIG 2

To facilitate the application of the apparatus to any rod, a clamp or distance piece H—Fig. 3—is added, by which the two clips, B and C, may be held at the right distance apart, and with the axes of their set-screws parallel. This makes it in many cases unnecessary to prepare the rod beforehand by punching or drilling holes for points of the set-screws; the clamp is readily held so that the clips stand fairly round the rod; the set-screws are advanced to grip the rod, and the clamp is then removed by releasing the screws G G. The connection of the clamp to each of the clips is by means of three points gearing with a hole, slot, and plane. The clamp is specially convenient when the strain of the specimen has been carried beyond the elastic limit, and it is desired immediately to reset the clips to the standard distance apart after the length between them has been materially changed by the permanent extension of the specimen.

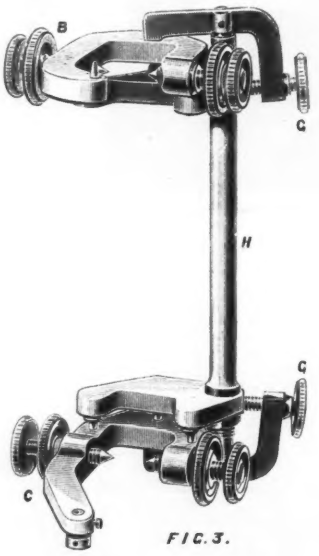

FIG. 3.

Another form of the apparatus designed for use on the members of actual structures is shown in Fig. 4. There are essentially the same parts, but the arrangement is altered in order to make all the apparatus lie on one side of the piece under examination—a desirable and often necessary condition in the application of the instrument to such pieces as the girder flanges. The clips are—as in Professor Unwin's extensometer—adjustable to wide or narrow bars. The pieces B and C engage by means of a screw point in a hole, the necessary pressure being supplied by springs, with the effect that the apparatus can be used in any position, horizontal, vertical, or inclined, as in the figure. The sighted wire Q is on a prolongation of C beyond P, giving a mechanical multiplication of three to one. Between the objective and the eye-piece of the microscope is the box N, containing a series of two totally reflecting prisms, which turn the line of sight through two right angles. This arrangement keeps all parts of the instrument compactly together on one side of the bar or plate under test. A clamp is provided at J, which, by the tightening up of a single nut, disengages P from its hole and fixes the two portions, B and C, in relation to one another, so that the instrument may then be handled as a rigid whole, and be readily applied to the bar which is to be tested, the axes of the clips being then parallel and at the proper distance apart. When the instrument has been put in place, and the clip screws tightened up, the nut J is released, P comes into gear, and things are ready for the observation to be taken,

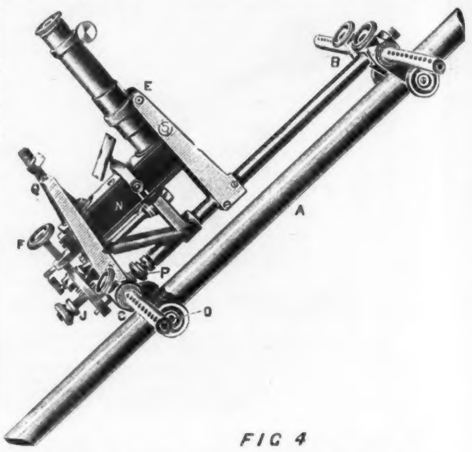

FIG 4

The following are examples of tests made with the author's extensometer in its laboratory form. The pieces were loaded, in tension, by means of the 50-ton Wicksteed single-lever testing machine of the Cambridge Engineering Laboratory. The machine is worked by a hydraulic intensifier, which affords a particularly convenient means of varying the load gradually without shock and without setting the weigh beam into oscillation. Except when otherwise stated, the increments of load were made at intervals of about one minute, that interval sufficing for the adjustment of the load to a new value, and for reading the extensometer. The unit of the extensometer scale readings is in all cases $\frac{1}{50000}$in.

(1) Turned bar of mild steel. Diameter, 1·249in. Length under measurement, 8in. Temperature, 57 deg. Fah. Zero of extensometer set at 400. Results of three successive loadings within the elastic limit:—

Load in tons.	Extensometer readings.			Differences.		
	First loading.	Second loading.	Third loading.	First loading.	Second loading.	Third loading.
0	400	400	400	—	—	—
2½	461	461	461	61	61	61
5	522	522	522	61	61	61
7½	583	583	583	61	61	61
10	645	645	645	62	62	62
12½	707	706	707	62	61	62
15	769	768	768	62	62	61
17½	830	829	830	61	61	62
20	892	891	891	62	62	61
0	400	400	400	492	491	491

Each ton corresponds in this case to a stress of 0·817 ton per square inch. Taking the whole extension due to 20 tons to be 491, or 0·00982in., Young's modulus is

$$E = \frac{8 \times 20 \times 0{\cdot}817}{0{\cdot}00982} = 13{,}310 \text{ tons per square inch.}$$

(2) Turned bar of tool steel. Diameter, 0·706in. Length under measurement, 9in. Temperature, 57 deg. Fah. The bar had not been previously loaded beyond 6 tons.

The load was then removed, observation being taken at these stages:—

Load.	Extensometer.
10	950
7	693
5	523
0	101½

Here each ton of load corresponds to 2·56 tons per square inch. The mean extension up to 10 tons is 84·7 per ton, and corresponds to a Young's modulus, E, of 13,600 tons per square inch. The extension per ton increases slightly, but perceptibly, with the later loads, although the almost complete absence of set after 12 tons, and even after 14, shows that there was no very clear passing of an elastic limit, even under the greatest strain of 35·8 tons per square inch. There is just a trace of hysteresis in the relation of strain to stress which shows itself in the removal of the load.

These two examples, relating as they do to cases where Hooke's law of the proportionality of strain to stress is very approximately true, may be taken to serve as tests of the sensibility and accuracy of the extensometer.

In the examples which follow, the limits were passed within which Hooke's law applies. In augmenting the stress so as to pass these limits, it very generally happens that one of the first evidences of overstrain is a time effect—a creeping up of the extensometer reading—while the load is kept constant for a few minutes. This creeping, which is a familiar phenomenon in the measurement of strains, can usually be detected a good way before the yield point is reached. It is associated with failure in proportionality of strain to stress, and also with permanent or semi-permanent set. In certain conditions of the material as regards previous treatment, this creeping is far more marked than in other conditions. It shows itself most when the piece has, immediately before the test, been subjected to a load sufficient to cause permanent yielding to occur. But if the same piece is allowed to rest for some days, and is then re-tested, the tendency to creeping is found to have disappeared or to be much reduced in consequence of the hardening and recovery of elasticity which the overstrained material undergoes with the mere lapse of time.

---

[*] From the "Proceedings" of the Royal Society, vol. 58.

The following observations were made with a turned rod of common wrought iron, the original diameter of which was 0·697 inch—section 0·381 square inch. Length under measurement, 9in. Each ton of load corresponds to 2·65 tons per square inch. The rod was annealed after being turned. The first loading, after annealing, gave the following results:—

(3A.) *Common iron, annealed.*

	5·8	773	Creeping to 774 in 10 seconds.		
	6·0	810	Creeping to 820 in 1 minute.		

With this load of 6 tons the yield point was reached. The creeping under the load was at first slow, then gradually became accelerated, and finally, the sighted wire of the extensometer ran quickly off the scale. At the same time the oxide formed in annealing began to come off in the way characteristic of the yield point. The scaling of the oxide began at one place in the bar and spread gradually in both directions. The load of 6 tons was kept on without alteration for about three minutes while this was happening, and when it was removed there was a permanent extension of 0·10in. on the marked length of 9in.

The extensometer was immediately reset to the normal length of 9in., an operation which occupied two or three minutes more, after which the bar was reloaded as follows:—

(3C.) *Same Piece after Stretching by a Load of 6 Tons.*

	—	208 After 45 minutes	—

These figures show how widely different are the elastic qualities of an iron bar in its primitive annealed condition, and in the condition in which it is put by overstrain. In the first condition there is almost no evidence of creeping or "elastische nackwirkung" up to, say, 5 tons of load, and Hooke's law is nearly valid. Immediately after an overstrain there are distinct evidences of creeping at lower loads, and when these lower loads are removed, there is the same kind of thing in the unloaded state, namely, an apparent set which disappears in whole or in part when time is allowed for the creeping to take effect. And further, after the overstrain there is no longer nearly so close an agreement with Hooke's law; a given increment of load produces notably more strain at high loads than at low ones. In loading and unloading there is now much hysteresis in the relation of strain to stress.

In the overstrained state the lowest loads produce not much more strain than they did in the primitive state; the value of Young's modulus so far as very small strains are concerned is scarcely changed. But if the modulus be calculated by reference to the effects of higher loads, it will be much smaller in the overstrained bar. This has been noticed by Bauschiger, who has also observed the tendency, illustrated in tests to be described below, which iron and steel show to recover their elasticity with the lapse of time, after overstrain has taken place.*

On resuming the above experiment, forty-five minutes after the previous load had been removed the influence of the overstrain was still conspicuous.

Load in tons.	Extensometer.	Difference per ton.

6	833	—
—	850 After 1 minute.	—
0	244	—
—	240 After 1 minute.	—

The bar was then taken out of the testing machine and left to itself for five days. On the fifth day the following readings were taken; they show in a striking way the effect of this interval of rest:—

(3B.) *Same Piece after Resting for Five Days.*

6	782	97
0	200	—
6	782	—
0	200	—

The tendency to creep has now practically disappeared so far as this range of load is concerned; the strain is very nearly proportional to the stress, and there is no set. It will be remembered that 6 tons was the greatest load formerly applied, and that it brought the piece to the yield point in the original test. The loading was then resumed, and was carried a stage further to see how far the new yield point would be above the old one.

0	600	Showing 400 divisions, or 0·008in., of further permanent extension.

The zero of the extensometer was now brought back to 200, and the loading was immediately repeated, to see whether this small amount of further overstrain had undone to any extent the molecular settlement which had been going on during the five days of rest.

Load in tons.	Extensometer.	Difference per ton.

0	204	Creeping back to 202, but not further.

It is clear from these figures that the elasticity has again been to some extent injured by the overstrain at the 7-ton load, small as that was, and one effect is that even a load of 6 tons now produces some persistent set. The following are values of Young's modulus E for this bar calculated from the foregoing experiments—3A, 3B, and 3C:—

Primitive Annealed State (3A).

Mean extension from 1 to 4 tons = 94·5 per ton.
E = 12,500 tons per square inch.

Immediately after passing yield point (3B) the diameter was reduced by the set to 0·693in., and the section to 0·377 square inch.

Extension for first ton = 97; E = 12,310.
Mean extension from 0 to 2 tons = 97·5; E = 12,250.
Mean extension from 0 to 4 tons = 100·2; E = 11,910.
Mean extension from 0 to 5 tons = 101·4; E = 11,770.

After elastic recovery by resting for five days (3C)—

Mean extension from 0 to 6 tons = 97; E = 12,310.

After a small amount of further overstrain—by applying 7 tons—

Extension for first ton = 97; E = 12,310.
Mean extension from 0 to 6 tons = 99; E = 12,060.

Similar results have been obtained in tests of other bars, of mild steel, comparatively hard steel, and Lowmoor iron. In every case overstrain has produced a like fatigue of elasticity, and elastic recovery has followed during an interval of some days or weeks of rest. In several examples the process of passing the yield point has been watched in the extensometer, and has been seen to take place in the same manner as in test (3A). Creeping, which has been slightly visible under lower loads, takes place at first slowly, then it gradually gets faster, though no change is made in the load. This may go on for a minute or two before the crepitation of oxide begins. The following is an instance noticed in testing a bar of mild steel:—The load having been increased a step, and kept constant, there were

3 scale-divisions of creep in the first minute.
9 ,, ,, ,, second ,,
320 ,, ,, ,, third ,,

after which the index of the extensometer raced off the scale. In another case the writer noticed creeping going on quite slowly, when a sound of crepitation was heard. On looking at the bar it was seen that the crepitation had begun near one end, beyond the clips. As soon as it spread far enough to reach the clip there was, of course, a rapid movement of the index.

The following test will suffice in further illustration of the influence of overstrain and subsequent rest. It was made on a turned bar of moderately hard, or semi-mild steel, which had not been previously loaded beyond 6 tons. The diameter was 0·705in., and the section 0·390 square inch. The length under test was 9in.:—

As in the example already given, the influence of overstrain is apparent (1) by the presence of creeping or "nachwirkung," and (2) by the progressive growth of the differences as the load increases. The first ton or so produces little more strain than it did before the overstrain took place, but the eighth ton produces a-quarter as much again.

An hour after the yielding had taken place the load was agian re-applied in stages of one ton as follows, and the extensometer readings already show something of elastic recovery through rest. They are given in the following table, along with readings taken on the following day and on subsequent days. It is interesting to notice the rather slow progress of the elastic recovery from day to day. It takes place much less rapidly in this comparatively hard metal than in milder steel or in wrought iron. To facilitate comparison the readings taken immediately after the overstrain are repeated here:—

Successive Loadings of the same Piece, after various Intervals of Time.

These figures show that even after three weeks the elastic recovery is still somewhat incomplete. This is the more remarkable when it is borne in mind that the testing is done here with a load of 8 tons only, a considerably smaller load than that which had been applied to produce permanent set—namely, 11 tons. The imperfection which the elasticity still shows after three weeks of rest would be more conspicuous if the loading were extended beyond 8 tons.

Throughout this group of tests evidences were seen of much elastic "nachwirkung." If a load exceeding, say, 4 tons, was left on for a few minutes there was continued extension, amounting sometimes to as much as five scale divisions. And when the load of 8 tons was removed there was, as the table indicates, a gradual retraction which in a few minutes destroyed the apparent set observable at the moment of removing the load. In the final observation (4H) this action had almost wholly disappeared, but even then a trace of it could be detected.

As elastic recovery goes on in the days or weeks following overstrain there is a gradual return towards Hooke's law, or as it might be described in other terms, a gradual straightening out of the stress-strain curve. So long as the recovery is incomplete there can scarcely be said to be any elastic limit, in the sense of a point below which there is strict proportionality of strain to stress.

For the Young's modulus of this bar the tests give the following values:—

(4A.) Primitive condition (before overstrain).
Section 0·390 square inch.
Mean extension from 0 to 8 tons = 85·6 divisions per ton.
E = 13,480 tons per square inch.

(4B.) Immediately after stretching past the yield-point by 11 tons.
Section 0·385 square inch.
Extension for the first ton = 87; E = 13,440.
Mean extension from 0 to 8 tons = 97 per ton; E = 12,060.

(4G.) After 5 days' rest.
Extension for the first 2 tons = 86 per ton; E = 13,600.
Mean extension from 0 to 8 tons = 93·7 per ton; E = 12,480.

(4H.) After 21 days' rest.
Extension for the first 2 tons = 85·5 per ton; E = 13,670.
Mean extension from 0 to 8 tons = 87·5 per ton; E = 13,370.

The behaviour of iron or steel when "fatigued" by overstrain, and before recovery of elasticity has taken place through prolonged rest, much resembles that of a brass rod in its normal state. The following is a test of a turned rod of rolled brass with a section of 0·386 square inch. The length under measurement was 9in.

Load.	Extensometer.	Difference per half-ton.
0	200	—
½	281	81
1	362	81
1½	443	81
2	525	82
2½	607	82

0	202	—
5	1036 to 1037	—
5½	1129 to 1130	93
0	212 to 210	—

Under the higher loads there was a distinct creeping, with a corresponding creeping back after the load was removed.

Taking 163 divisions per ton as the extension under small loads, the value of E is 7160 tons per square inch.

The last test to be cited is that of a "steel" casting of the specially pure kind now extensively used to form the cores of dynamo magnets. The rod was turned from a steel casting by the makers—Messrs. Edgar Allen and Co.—and had been submitted to the writer for a magnetic test, which had shown it to have exceptionally high permeability under strong magnetic forces. It consisted of nearly pure iron. The diameter was 0·753in.

Load.	Extensometer.	Difference per half-ton.	Set.
0	200	—	—
½	237	37	—
1	273	36	—
1½	310	37	—
2	347	37	—
2½	384	37	—
3	423	39	—
0	204	—	4 (apparently persistent)
3	424	—	—
3½	468 to 470	44 to 46	—

	785 after nine minutes.		
0	447	—	247
4½	798	—	—
5	1200 running slowly off the scale		

The mean extension from 0 to 2½ tons is 73·6 per ton, which makes E = 13,740 tons per square inch.

MR. THOMAS GALLON.—The name of Mr. Thomas Gallon, whose death was announced in our last impression, was incorrectly spelt Gallow. It may be added that his hydraulic capstans were awarded the gold medal at the International and Electrical Exhibition, Edinburgh, 1890.

---

* See also a paper by the present writer—"On Certain Effects of Stress," Roy. Soc. Proc., No. 205, 1880—which gives instances of the rise of the yield point with lapse of time, a phenomenon evidently having a close relation to the rise of the modulus.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

EARLY LOCOMOTIVES.

SIR,—Mr. Stretton has given us his opinion concerning the bow-shaped locomotives, viz., "No engine was ever built for the Great Western Railway with such a projector." Here again, unfortunately, Mr. Stretton's opinion is at variance with the actual and indisputable facts. It is well known to students of early Great Western Railway history that Dr. D. Lardner, in the autumn of 1838, for a period of three months, was experimenting with the original broad gauge engines, on behalf of Mr. N. Wood, to enable the latter to prepare his report to the directors of the Great Western Railway. After the report had been published, Dr. Lardner published various magazine articles, &c., giving the results of his experiments. In the *Monthly Chronicle* for 1839, page 191, Dr. Lardner states: "The only expedients which we have seen on that railway"—*i.e.* the Great Western—"are what have been called—from their peculiar shape—the *boat engines*, and these are, or were lately, incapable of working passenger trains, and were used as ballast engines. We have always been informed that the expedients for cutting the air were found—to use a well-known phrase—*not to answer*." Surely Mr. Stretton, in the face of the above statement made by Dr. Lardner, will withdraw his remark "that no engine was ever built for the Great Western Railway with such a projector." Nor is the above the only reference Dr. Lardner makes to these prow-shaped locomotives. At the meeting of the British Association held at Birmingham in 1839, Dr. Lardner read his well-known paper "On Railway Constants and Resistance of Air to Railway Trains." In this we read: "The form of a boat or beak having been given to some of the engines on the Great Western Railway apparently with the view to diminish the effect of the atmospheric resistance, Dr. Lardner determined to ascertain how far such a form would produce any practical effect." Tables 4, 6, and 7 describe these experiments.

Perhaps Mr. Stretton will explain why Dr. Lardner made the eight experiments recorded in the three tables, if the engines did not exist.

I have recently been in communication with a gentleman who represented Mr. Brunel at Dr. Lardner's experiments, but, unfortunately, he is unable to remember anything definite in connection with them.

I have heard from Mr. Wilson that the engine illustrated in THE ENGINEER of 3rd inst. was the "Grasshopper." So it appears that the "Ajax" and "Grasshopper," with 10ft. driving wheels, composed of discs of iron, and with a projecting prow, were found unsuitable for passenger train traffic, and were used for leading ballast trains during the construction of the Great Western Railway.

Mr. Crampton gives the following dimensions of the "Ajax":—Area of fire-grate, 10·22ft.; total heating surface, 474ft.; diameter of driving wheels, 10ft.; diameter of cylinders, 14in.; stroke, 20in.; surface in fire-box, 57·3ft.; cubic contents of both cylinders, 7·09ft.; proportion of capacities of cylinder to the wheel, 1 : 1·41. The "Grasshopper" was apparently of the same dimensions. It will be observed that these dimensions are quite different to those of the "Hurricane," the other 10ft. wheel engine.

January 17th. G. A. SEKON.

MECHANICAL ROAD CARRIAGES AND FEATHERWEIGHT MOTORS.

SIR,—Considerable attention having been drawn to a certain motor on account of its extreme lightness in relation to its power, we should like to be allowed a few criticisms on the subject of very light motors for road carriages. Except for application to cycles, our present opinion is not favourable to extreme lightness of motor for this service. We should give preference to motors of from 1½ cwt. to 3 cwt., of 2-horse power to 4-horse power. In our extensive experience of machine tool making, we have always found, as is generally recognised in all classes of machinery, that, independent of good foundations, perfect balance of moving parts is by no means the only essential to steadiness and to the accuracy and finish of work turned out. The "anvil principle," or the absorption of "trepidation"—we call it vibration—by properly distributed mass is a most important necessity for overcoming objectionable vibration; in the case of carriage motors with the absence of foundation, this principle assumes an even greater importance, and a motor sufficiently heavy to absorb its own vibrations is consequently to be aimed at. What the minimum weight of such a motor should be depends, of course, upon its design, and is a matter of experiment for each type and power of motor employed. Again, the weight of motor and carriage as a whole, and its distribution, should be considered in relation to its power and weight for adhesion. The slipping of some of the wheels on the snowed roads of Chicago was probably due to excess of power over adhesive weight. The relation of these to each other is also a matter of experiment, but a moderate or even a substantial weight is evidently necessary. The tractive force required for a motor of, say, 3 cwt. is so small that the difference between this and one of, say, 20 lb. need not be taken into consideration.

The durability (?) of a motor of 2-horse power, weighing 20 lb., is very speculative. It is said, "The good die young." It is mechanically more satisfactory, however, if the old die good, and the life of a 20 lb. 2-horse power motor, though it may be brilliant, must of necessity be brief.

We hope shortly to furnish you with illustrations of motor vehicles we have now in progress, and to give our experience on some of the above points. In the meantime, we should like, if permitted in a technical letter, to observe that as Britain has recently shown she can hold her own against the world politically, she will also be able to do so mechanically, in the matter of motor vehicles. We intend to be amongst those to prove this, so that anyone who prefers home-made goods to those "made in Germany"—or America—may satisfy their patriotism by placing their orders with firms at home. LISTER AND CO.

Keighley, January 18th.

A QUESTION OF TRAIN RESISTANCE.

SIR,—I think it is possible that I may be able to throw a little light on the question of train resistance, with which you have dealt in your last impression. I assume that you do not doubt that a speed of nearly seventy-three miles an hour was reached on the Lake Shore and Michigan Southern Railway, on the 24th of October, but that you do doubt that the resistance was only 15 lb. per ton. I think it can be shown that the resistance was much higher, and that neither you nor your American critic have done full justice to the locomotive. I have received from a friend in America a species of circular which is being sent out, containing particulars of three runs—that under consideration; one made on the New York Central on the 11th of September; and one on August 22nd and 23rd, during the race to the North, made on the West Coast route. From this circular a few particulars of interest, not previously published, are to be gathered. The circular is, however, silent as to gradients, which is, of course, the important point.

I find that the piston speed of the six-coupled engine was on the average 1484ft. per minute. The united area of the two pistons was 430in., deducting piston rod area, and $\frac{430 \times 1484}{33,000} = 20$-horse power per pound of cylinder pressure effective. The boiler pressure was 180 lb. on the square inch, and I do not think it is too much to assume that the average effective cylinder pressure was about 50 lb.; this gives us 1000-horse power for the engine; it is very probable that it was more. Nor is this remarkable, for although the engine has only 17in. by 24in. cylinders, the boiler is enormous. There are 1700 square feet of heating surface, and what is of yet more importance, 30 square feet of grate. There is no doubt that the engine was provided with the best coal that could be got, and started with the tender tank full of hot water. No device that was known to a fireman was neglected. The engine was run with but one consideration—speed, and no doubt the enormous grate disposed of coal as fast as it could be got through the fire-door under the influence of a powerful draught. The production of steam representing 1000-horse power under such circumstances by a boiler with 1700 square feet of heating surface would not constitute a very remarkable performance. In this country we have had 1000-horse power out of 1400 feet of surface with easy firing.

Now 1000-horse power at 73 miles an hour gives a tractive effort of 5121 lb. That is the total tractive effort of the engine, which was expended partly in propelling itself and the tender, partly in pulling the three cars of which the train consisted. The total weight of the train was 506,500 lb., or 226 English tons, and $\frac{5121}{226} = 22·61$ lb. per ton, which is a far more rational figure than 15 lb.

The engine and tender weighed 202,000 lb. or, say, 90 tons. If we take its resistance, including friction, at 40 lb. per ton, we have 3600 lb. tractive effort, leaving 1521 lb. to haul the cars. They weighed 304,500 lb., or, say, 135 tons, and $\frac{1521}{135} = 11·26$ lb. per ton. All these figures give a very small resistance, and there can be no doubt but that the resistance was very small, but not necessarily anything like so little as 15 lb. per ton for engine and train together.

But the moment we admit that a small tractive effort will give a high speed, the favourable influence of a descending gradient comes out with remarkable prominence. Thus, 15 lb. is very nearly the 150th part of a ton. If, now, the resistance of the American train was but 15 lb. per ton, then it follows that a speed of 73 miles an hour must be attained and maintained for a distance of 86 miles on a down gradient of 1 in 150, engine and all, just sufficient steam being admitted to the engine to prevent pumping action in the cylinders. This seems a very large demand on our faith. I wonder if any of your contemporaries in the United States have looked at the matter from this point of view. But let me push the argument a little farther. Assume that the resistance was nominally, say, 23 lb. per ton for engine and train, but that the train was running down a gradient of 1 in 2240, then the real resistance was 24 lb. per ton. If the gradient was 1 in 1120, then the resistance was 25 lb. per ton; if the gradient was 1 in 500, the resistance would be 27·4 lb. per ton. The only information to be had about the gradients is that from Erie to Harbour Creek the road rose at the rate of 15ft. per mile, up which a speed of 55 miles an hour was maintained.

I think the facts go to show, not that the resistance was very small, but that the power of a big engine run in a very reckless way is great. It must be remembered that the six-coupled engine is half as large again as the most powerful locomotives in this country, measuring the power by the size of the boiler, which is the real test. With a slashing draught such as there must have been when the driving wheels were making 371 revolutions per minute, the huge grate would have got rid of coal in a way to surprise one, and coal means speed and power. I see no reason to doubt that the pressure was maintained all through the run at 170 lb. or thereabouts, and that being so, the average cylinder pressure might have been nearly 70 lb. or 80 lb. As you have said, what is now lacking is more detailed information. Perhaps Mr. Canniff, the general superintendent of the Lake Shore and Michigan Southern Railway Company, will let the railway world have it. SIGNAL POST.

Shrewsbury, January 21st.

SLIDE VALVE FRICTION.

SIR,—I notice a letter from "Frottoir" on the above subject in your issue for this week, in which he states that he had experimented with an engine giving 28 brake horse-power, and found that about 0·6-horse power was required to work the slide valves. I presume this was the difference observed on the brake when the slide valves were balanced, as stated by him, and unbalanced or working as ordinary slide valves. He also states that the conclusion arrived at was that about 5 per cent. of the indicated horse-power was absorbed in working the slide valves. It is with reference to this that I wish to call your attention.

Let x = the percentage of the horse-power absorbed in driving the slide valves, then $\frac{x}{100} = \frac{0·6}{28}$; $\therefore x = \frac{60}{28} = 2·14$ per cent. of the brake horse-power, which will be less than this when compared with the indicated horse-power; thus, let us assume the engine had a mechanical efficiency of 75 per cent., then the relation between the B.H.P. and I.H.P. will be $\frac{\text{B.H.P.}}{\text{I.H.P.}} = 0·75$, and therefore $\text{I.H.P.} = \frac{\text{B.H.P.}}{0·75} = \frac{28}{0·75} = 37·33$ I.H.P. In this case we have $\frac{x}{100} = \frac{0·6}{37·33}$; $\therefore x = \frac{60}{37·33} = 1·6$ per cent. of the I.H.P.; a result which agrees very well with that stated in my letter contained in your issue of the 10th inst. EDWARD J. M. DAVIES.

24, Harrington-square, London, N.W.,
January 18th.

BELGIAN GIRDERS IN MANCHESTER.

SIR,—An enterprising Press Cutting Agency sends me your note, from page 71 of your current issue, about an extraordinary instance of the success of Belgian competition in the Cleveland district, and mentions my name as having bought girders in Belgium. I desire to say that this is inexact. My resident engineer tells me, on inquiry, that he bought some girders from a local English firm, and the iron may have been Belgian, but I did not go out of my way to buy a few paltry girders in Belgium. The whole item does not amount to £50 out of a contract going heavily into five figures.

But why make such a mountain out of a molehill? Are you not aware that every pound—as I have been told by Middlesbrough men—of the iron roof of the large railway station in Middlesbrough is made of Belgian iron? That is a fact worth knowing—not a repetition of the old experience common in almost in every English town, that Belgian girders are used for building purposes. To quote the words from Hamlet—with the necessary alteration—"Something is rotten in—the state of—Middlesbrough," and what that is, is, I am told, sufficiently stated in the interesting report of the British Iron Trade Association on "Continental Competition in the Iron and Steel Trades." Both workmen and employers are at fault, I believe, and the evil, although increasing at present, is, I am sure, still capable of being cured, if the lessons given by facts like the one above, and by the statements of that report, are properly digested by those concerned.

20, Mount-street, Manchester, HENRY SIMON.
January 21st.

ASSOCIATION OF WATERWORKS ENGINEERS.

SIR,—The account which you give in your issue of the 17th inst. of the meeting of waterworks engineers at Nottingham on the 11th inst. is somewhat misleading, and calculated to defeat the objects I and others had in view when urging, and eventually getting the meeting to adopt only resolutions of a tentative character so far as concerns the constitution of the Association in question. The resolution adopted was, "That a Provisional Committee be formed to consider fully the constitution of the Association, the status and qualification of its members, and the necessary rules and regulations, and to report to a meeting of the promoters to be held at as early a date as possible, and that a chairman of such Committee and a Provisional Committee be now elected."

The question of qualification, classes of members, method of election, subscriptions, places and times of meeting, the number, election, and status of the managing Council or Committee, and of the president, secretary, and others, have to be decided by the general body after the Provisional Committee have reported thereon, and it is to be hoped that all who can possibly attend the meeting to consider the Committee's report will do so.

It will depend entirely upon the general character of such report whether or not many waterworks engineers will consent to join the Association, as although in full accord with the generally expressed objects of the same, we feel that there are some points of vital importance to be settled, especially that relating to the qualifications of the members and officials.

WM. MATTHEWS, Mem. Inst. C.E.

Waterworks Engineer's Department,
Southampton, January 23rd.

A PUMPING PROBLEM.

SIR,—I have read the two articles in your issues of the 15th and 22nd November, 1895, under the above heading with great interest, for about two months ago we resumed sinking our main shaft, and after getting down a little distance we found the playing of a quantity of water equal to 3000 gallons per hour, partly from springs in the vein and from surface into the shaft rather unpleasant, and to get over the difficulty I connected it to the suction pipe of the sinking pump, and it has been in it ever since. One point worth noting is that in blasting the pump can continue working on the upper level water when the suction pipe is entirely out of water, either by hauling up the pump or drawing up the telescopic suction.

T. B. FREEMAN LOWE, A.I.M. AND M. AND C.E.

The Wassau (G.C.) Mining Company,
Cape Coast Castle, January 4th.

MOTOR CARRIAGE NOTES.

IF any of those interested in the future of motor carriages on common roads have still any lingering doubts concerning the legality of the use of these vehicles under existing laws, licence or no licence, they may perhaps be dispelled by the latest magisterial decision, a decision given with a full knowledge of the present feeling against the law as it stands. Mr. J. H. Knight, of Farnham, who was fined by the magistrates in November last for using a motor carriage on the highway, applied to the Surrey County Council for permission to use the same under certain restrictions as to speed, and within certain hours, and has received the following reply:—

[COPY.]

Surrey County Council, County Hall,
Kingston-on-Thames, January 16th, 1896.

LOCOMOTIVES ON HIGHWAYS.

Dear Sir,—Your communication of the 6th inst. was read and fully considered by the Highways and Bridges Committee at their last meeting, and in reply I was directed to say that the Committee sympathise with you in your endeavours to secure progress for the movement relaxing the existing restrictions under which locomotives are at present suffered to be used upon highways. But I was also directed to say that they cannot give the permission you ask for—viz., that your locomotive should be used upon the highways in your neighbourhood, although you would undertake not to pass through the town of Farnham in the afternoon, nor to run more than eight miles per hour.

Yours faithfully, R. H. WYATT, Clerk of the Council.

John Henry Knight, Esq., Barfields, Farnham.

A PAPER was read before the Civil and Mechanical Engineers' Society, by Mr. F. R. Simms, C.E., on "Mechanical Locomotion on Common Roads," on January 16th. This subject the author dealt with in an interesting manner, putting before the meeting the salient features of the history of the subject, and drawing attention to the more important points in connection with the matter. The pernicious influence of the Acts relating to mechanical locomotion was distinctly set forth; but, in the author's opinion, these Acts had unintentionally produced good to the community, which might be set, to some extent, against the evil that had arisen from their operation. This good was through the attention to machines capable of being driven otherwise than by mechanical power, resulting in the bicycles and tricycles of to-day.

IN our recent accounts of motor carriage trials in America, the Benz motors and carriages were several times referred to. We may therefore mention that Mr. T. H. Warland informs us that the Acme Oil Motor Carriage Company, of 59, Mark-lane is the sole agent in the United Kingdom for the Benz motor carriages and engines as made at Mannheim. These motors are, it will be remembered, benzoline motors.

THE directors of the Crystal Palace have decided to arrange for an international exhibition of every kind of road vehicle that has ever been used, including private, public, pleasure, military, business, and motor carriages. The exhibition is to take place in May and June or June and July, and an influential committee has been formed to make all the necessary arrangements.

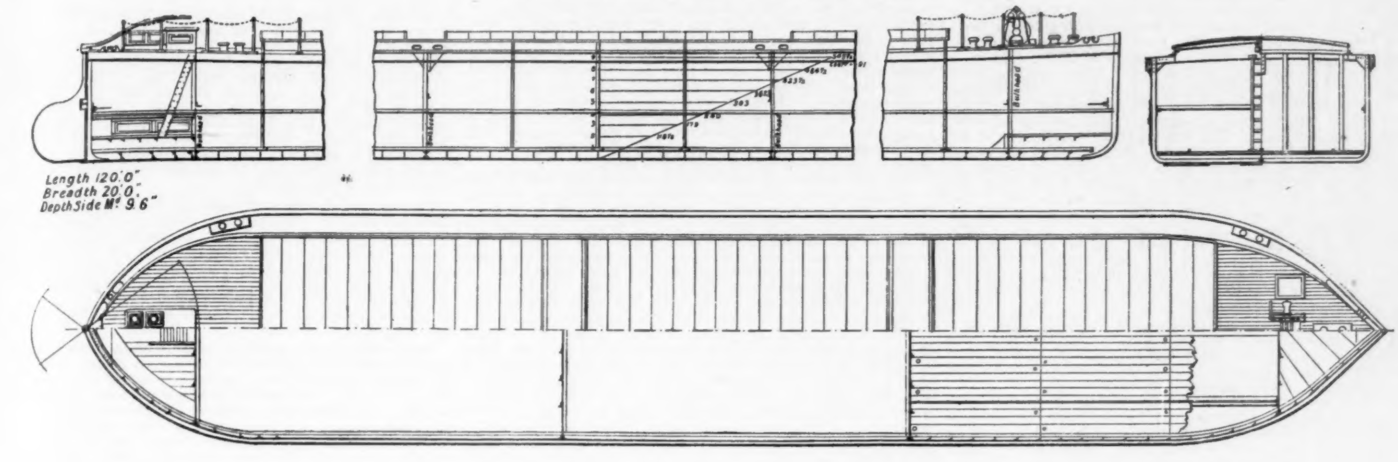
A SPORTS, Games, and Industrial Exhibition is to be opened at Scarborough in May, and remain open until October. Classes 19 and 20 relate to self-propelled conveyances, and to motors for them, and gold and silver medals and prizes in money will be given for them. Mr. Joseph Davis, Piccadilly-mansions, Piccadilly-circus, is the general manager.

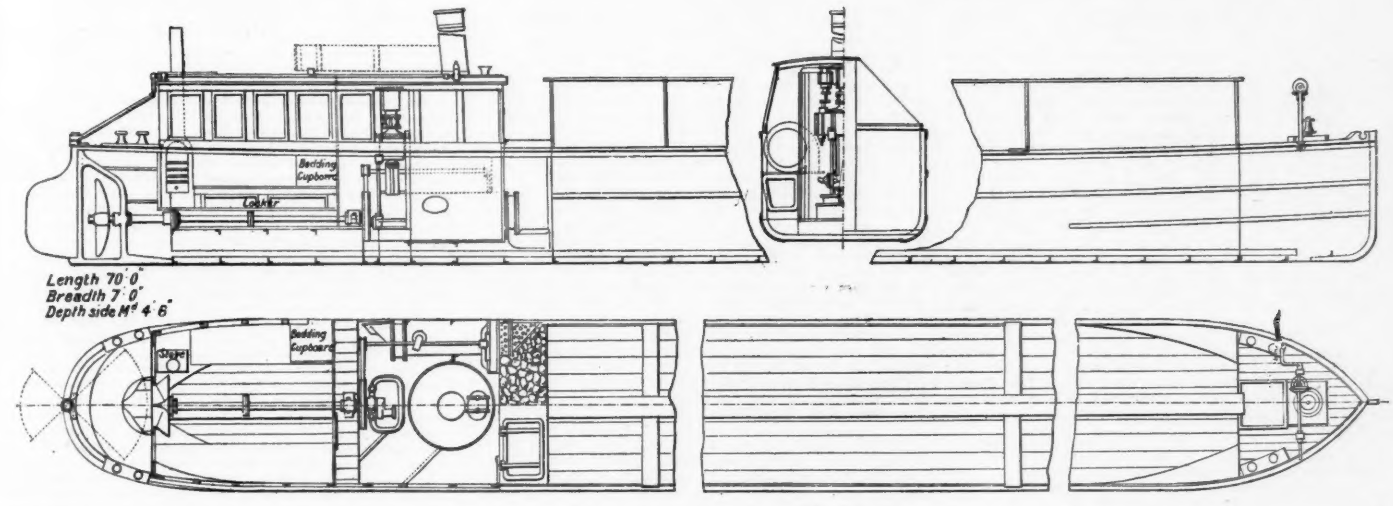
SIR DAVID SALOMONS is having two Serpollet steam carriages built—one as a small omnibus or parcels van, and one a light high-speed vehicle, suitable for military aide-de-camp work.

THE MECHANICS OF HORSE HAULAGE.—A very interesting lecture on "The Principles of Economy in Civil and Military Transport" was given by Mr. T. H. Brigg at Chelsea Barracks on Wednesday evening. Sir Redvers Buller presided, and among those present were Lord Methuen, Major Ross, of Bladensburg, and other officers. Sir Redvers Buller said that Mr. Brigg had given a great deal of time, trouble, and engineering talent to the study of a subject that must be of very great interest to anybody who had anything to do with horses and haulage. He had devoted himself to perfecting a system which eased the labour of a horse, and enabled it to do more work for its employer. He had already passed from theory to practice, and had made an invention which would prove of great practical and economical value. Mr. Brigg then showed, by cleverly devised apparatus, a series of practical experiments, the nature and magnitude of the forces with which horses have to contend, not only in hauling their loads, but in counteracting as far as possible those forces which are introduced by the present arrangements of harnessing and shafts. He showed how it was possible that a vehicle or its load should help to take some load off the horse's feet while on the level, and automatically to change the amount and incidence of the load on his back to help him in getting up hill. He claimed, by automatic arrangements, to increase the life and earning capacity of a horse within a very short time by 50 per cent. He regretted that there was not a single institution in the world where the economy of the application of horse-power was taught, though more millions were invested in horses and carriages than in all the railways. If it was important to economise the force of engines, it was still more so to find out what contributed most to the earning capacity and humane treatment of the horse.

STEAM AND TOWING BARGES—WORCESTER AND BIRMINGHAM CANAL

MR. J. MCGREGOR, M. INST. C.E., ENGINEER



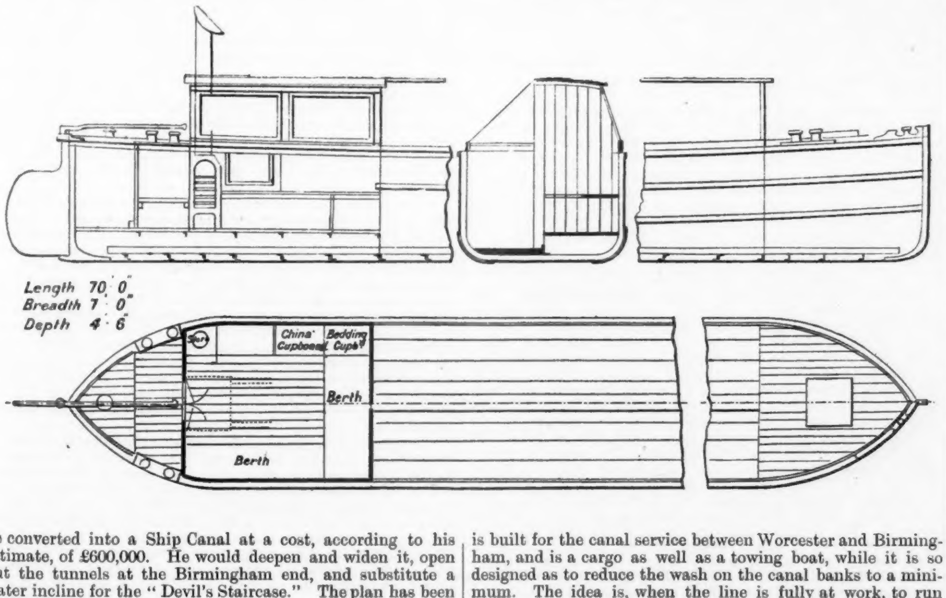


BIRMINGHAM AND THE BRISTOL CHANNEL.

We have already described in general terms the nature of the project for establishing direct water communication between Birmingham, the Midlands, and the port of Cardiff, by way of the Gloucester and Berkeley Canal, the canalised Severn from Gloucester to Worcester, and thence by locking-up to the Worcester and Birmingham Canal. Since Mr. Martin completed with really remarkable economy, the deepening of the Severn to an even 10ft. level, all was fair sailing from tidal water to Worcester. There progress was impeded by the condition of the Birmingham Canal, a narrow and shallow barge navigation, with a series of locks at Tardebigg, which rise nearly 300ft. within four miles. Mr. G. W. Keeling, C.E., has shown that this waterway could be converted into a Ship Canal at a cost, according to his estimate, of £600,000. He would deepen and widen it, open out the tunnels at the Birmingham end, and substitute a water incline for the "Devil's Staircase." The plan has been approved by engineering experts as practicable, and mercantile interests have pronounced it to be most desirable; but it remains at present an unrealised dream.

While this obstruction remained, it was necessary, for through communication between Birmingham and the sea, to construct vessels of a special type, capable of navigating inland waters, and yet seaworthy enough to cross the Channel between Cardiff and Sharpness. Boats answering to these requirements have been designed by Mr. J. McGregor, N.A., M. Inst. C.E., who is now in India, and whose great experience of inland navigation in Indian waters eminently qualified him to devise the class of vessel best suited to the purpose. The scheme of the Water Transport Company, thanks chiefly to the untiring energy of Mr. Robert Johnston, of Cardiff, has now passed beyond the stage of experiment. Boats of three different dimensions have been built, and are described in the subjoined plans. The larger steamerhas already made several trips to and from Cardiff and Worcester, and proved that the Westgate Bridge at Gloucester does not, as it was predicted it would, offer any difficulty in the free navigation of specially-constructed craft on the deepened river. Early in the year, it is expected, the whole of the pioneer fleet will be placed on the service, and it depends upon the extent of the trade thus to be developed or created how far the number of vessels, particularly the smaller craft, may be still further increased.

The large steamboat—it has been named A1—will carry cargo and take a train of barges in tow. The smaller steamer is built for the canal service between Worcester and Birmingham, and is a cargo as well as a towing boat, while it is so designed as to reduce the wash on the canal banks to a minimum. The idea is, when the line is fully at work, to run regular daily trips from Cardiff to Birmingham, dropping a barge here and there as circumstances require, as goods trains drop their wagons at wayside stations; and it is calculated that the journey between the Bristol Channel and the Midland capital will be made in twenty-four hours, after making all allowance for the delay at the Tardebigg chain of locks. The A1 is equally adapted to the coasting trade, or, with slight deck alterations, might voyage to the French and Irish ports. The second-class boats are suited to the navigation of any canal in the kingdom, in that respect fulfilling the description of "amphibious boats" used by our correspondent "Commerce," though they cost much more than the £150 specified by Mr. H. R. de Sales in a recent issue. It would be possible for the new barges to carry cargo to all points on the network of canals of which Birmingham is the centre; to make connection between the Severn Canal system and that of the Mersey, including the Manchester Ship Canal; and either through the Midlands, or by the Thames and Severn Canal, now in course of re-organisation, to open communication between the Bristol Channel and the navigations of the Upper Thames.



Private enterprise has so far found a solution for the problem as to how to utilise our neglected waterways; and that the Severn is a neglected waterway—that is, in relation to its natural advantages and the great opportunities it offers—is proved by the statement of Mr. William Riley, one of the largest timber importers in the country, that not a single extra ton of cargo has been carried on the river since the channel was dredged to a depth of 10ft. summer low level. The commercial benefits of the Cardiff and Birmingham water service are calculated by its promoters—though, of course, they are reckoning on the future—at a very high rate. The railway rates from the Welsh port to the hardware capital are from 5s. to 8s. more than they are from Bristol, because from Bristol there is competition, while from Cardiff there is practically none. Corn, timber, china clay, and flints for the Potteries, the raw materials of manufacture, will be borne inland at charges which it probably would not pay the railway companies to reduce their rates to. Hardware, ironwork, the produce of the innumerable small industries, and, in short, the various products of Birmingham and the Black Country, are regarded as sources of a profitable traffic between the seats of manufacture and the ports.

The success of the undertaking, moreover, would largely revolutionise the trade of Cardiff. Hitherto ships leaving that port have been loaded almost exclusively with coal and rails. A miscellaneous cargo is, we suppose, unrecorded among the clearances. A number of shipowners have undertaken to find accommodation for the miscellaneous goods transported by the new water service from the Midland district. These manufactures have until now been shipped from the Mersey or the Thames, at heavy railway charges to the ports. Freights rule low in the Bristol Channel, as, indeed, they do everywhere just now. But it is claimed that on the average they rule lower at Cardiff than elsewhere. This circumstance, together with the lower cost of water transport, it is anticipated, will divert a good deal of the export trade of the Midland manufacturing region from Liverpool and London to the Welsh port, which, in its turn, hopes by the same means to divert from more remote ports and from the railways a good deal of the oversea traffic consigned to Birmingham and the districts around.

One Way of Making a Speed Record.—Frequent mention has been recently made in the American newspapers of an alleged fast run on the Delaware Lackawanna and Western. It is stated, however, that when Mr. Ely, chief of motive power of the Pennsylvania, wrote to general manager Hallstead, asking for particulars of the dimensions of the engine and other facts which would throw light on the unusual performance, Mr. Hallstead replied: "This railroad company does not pride itself on high-speed performances; we do not have a straight level track, and we do not have four tracks to keep passenger trains away from freight; we do not have any '999' locomotives, and we do not have any 7ft. driving wheels; but we have some of the most accomplished liars east of Chicago, who have supplied the motive power on which the fast run was made."—*Railway News.*

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Cable incline railway.—The steepest inclined railway in the world is the new—second—cable incline ascending Lookout Mountain, at Chattanooga, and recently opened for traffic. Its total length is 4972ft., in which distance it makes a rise of 1450ft. There is another cable incline, and also an adhesion railway which has a total length of eight miles. The new line is perfectly straight, while the grades range from a minimum of 12 per cent. to a maximum of 68 per cent., or 1 in 1·47. There are two steam engines of 75-horse power driving two main drums 7½ft. diameter by gearing, the spur wheels being 8¾ft. in diameter. There are three boilers, 16ft. long and 5ft. diameter, and a smokestack 42in. diameter and 76ft. high. This hoisting plant is at the top of the incline. Powerful brakes are fitted to the drums and the engine shaft, the brake on the front drum being applied automatically when the car reaches the end of its journey, steam being also shut off automatically in case of any failure on the part of the engineman. There are two 1¼in. steel cables, guaranteed for 104,000 lb., which gives a factor of safety of 7. If either cable should break the motion of the pivoted bar to which they are attached would put in action a jaw brake gripping the heavy timber guard rails. The track is laid with 56 lb. flange rails, and on the steep grades the ties are bolted to longitudinal timbers to prevent creeping. Broken stone ballast is used. There are two rails up to the double-track passing place—which is 300ft. long—and three rails thence to the top. The cars are 32ft. long, with seats as in an ordinary American railway car, seating sixty passengers. There is communication between the conductor and the engineman. Part of the line is on trestle work.

Railway construction in 1895.—The mileage of new railways built, which has been decreasing year by year since the busy year of 1887, reached in 1895 the lowest figure that has been touched for twenty years. One record is about 1500, and another about 1700 miles, and the average of these is probably about right. No very long or important lines were built, most of the work having been in branches and extensions of main lines and small new local lines. The average length was only about ten miles. As so much of the total represents local lines, it is not unlikely that electric railways have had an effect in keeping such construction down to a low figure, although electric railways do not yet affect the construction of lines of any length or general importance. In some circles it is thought that the improvement of business, which is expected during 1896, will lead to a revival in railway construction, especially as labour and materials are cheap, and many good enterprises are waiting. On the other hand, it is thought that railway construction will not feel any great revival, and that no great projects will be undertaken for some years. Most of the work of 1895 was in the Western States, Texas and the Indian Territory being the only cases where the total exceeded 100 miles. The totals for the last ten years have been as follows:—1886, 8500; 1887, 13,000; 1888, 7000; 1889, 5100; 1890, 5800; 1891, 4300; 1892, 4100; 1893, 2600; 1894, 1800; 1895, 1600.

Compound locomotives.—Among the latest compound locomotives are two two-cylinder compound freight engines of the ten-wheel type, having six-coupled driving-wheels and a four-wheel leading truck or bogie. They were built for the Terre Haute and Peoria Railroad by the Pittsburg Locomotive Company, using that company's system of compounding, which is now in use on a number of engines in passenger and freight service, as well as on some tank engines for elevated railways, these latter having four driving-wheels under the boiler and a trailing four-wheel truck or bogie under the tank. The leading dimensions of the two new engines are as follows:—

Fuel	Bituminous coal
Gauge of track	4ft. 9in.
Total weight of engine in working order ..	127,000 lb.
,, on driving-wheels	101,000 lb.
Driving-wheel base of engine	11ft.
Total ,, ,, ...	21ft. 8in.
,, ,, ,, and tender ..	49ft. 9¼in.
Height from rail to top of smokestack	14ft. 7¼in.
Cylinders, high-pressure, diam. and stroke .	19in. by 26in.
,, low-pressure ,, ,, ..	29in. by 26in.
Slide valves	Balanced
Piston-rods, extended through cylinder cover	Steel, 3¼in. diam.
Type of boiler	Extended wagon top
Diameter of boiler at smallest ring	60in.
,, ,, back head	69in.
Crown sheet supported by radial stays.	
Stay-bolts, 1in. hollow stay-bolts	4in. pitch
Number of tubes	256
Diameter of tubes	2in.
Length of tubes over tube sheet	12ft. 5in.
,, fire-box, inside	108in.
Width of ,, ,, ...	32¾in.
Working pressure	180 lb.
Grates	Cast iron, rocking
Grate surface	24·0 sq. ft.
Heating surface in tubes	1653·0 sq. ft.
,, fire-box	152·0 sq. ft.
Total heating surface	1805·0 sq. ft.
Diameter of driving-wheels, outside of tire ..	56in.
,, and length of journals	8in. by 9in.
,, of truck wheels	28in.
,, and length of journals	5in. by 10in.
,, of tender wheels	33in.
Type of tender tank	Level top
Water capacity	4000 U.S. gallons
Fuel capacity	300 cu. ft.
Weight of tender with fuel and water	78,700 lb.
Type of brakes	Westinghouse—American automatic

Mail cars for electric tramways.—One of the principal electric railways of Brooklyn, New York, having about 250 miles of track, has recently put in service five new mail cars, under contract with the United States Post-office Department. They are combination cars, with a passenger compartment and a mail compartment, in which latter the letters are sorted during the trip. They are run according to a regular time-table, and on two routes about six or eight miles long, messengers at different points delivering and taking bags for the several branch post-offices near the route. Each car is 35ft. long over all, and the body is 24ft. long, being divided into two compartments 12ft. long and 7ft. 4in. wide. The platforms are 4ft. 6in. long, with rounded dashboards. The mail compartment, at the forward end of the car, is fitted with the standard mail car fittings, including 200 pigeon-holes, a pouch rack, sorting table, &c. This compartment is entered by side doors only, and there is a small window in the partition through which stamps can be sold to persons in the passenger compartment. A drop box is also provided at each side, so that persons on the street can mail letters. The passenger compartment has accommodation for twenty passengers. There are six cross seats with reversible backs, arranged as in steam cars, and a fixed seat against the partition and the end of the car, the end door opening on to the side of the platform. The seats are covered with spring rattan. The interior finish is of cherry, and in each window post is a push-button to ring the platform gong and signal the conductor to stop. There are ten lights and a central electric heater in the mail compartment, and eight lights and a consolidated electric heater in the passenger compartment. Platform lights and electric headlights are also provided. The cars are mounted on two Brill maximum-traction four-wheel trucks, in which the greater proportion of the weight is carried by the larger wheels, on whose axles the motors are mounted. They ride very easily on the new heavy tracks, laid with 10in. 90 lb. girder rails. The motors were made by the Westinghouse Electric Company, and the controllers by the General Electric Company. Each car is fitted with a Crawford fender and fixed wheel guards. The cars are very handsome, the outside of the body being painted white, picked out in red and gold, and the interior having natural wood finish of light colour and veneer head-lining. They were put in service during the week previous to Christmas, and greatly facilitated the handling of the heavy mails of that season.

Steel centreing for sewers.—In the construction of a large sewer at Denver, steel rings were used for supporting the centreing used by the masons. The ring consisted of two semicircles of steel rails weighing 25 lb. per yard, a section being selected having a height equal to the thickness of the lagging. The lower semicircle has the rail lead outward, the outer radius being that of the invert of the sewer. The upper semicircle has the rail flange outward, and the radius is shortened to allow for the thickness of the lagging. To each end of the lower half is riveted a short piece of the same section of rail, having a hole punched in the flange, a corresponding hole being punched in each end of the upper half of the ring. One of these pieces has its end cut on a slight bevel, corresponding to a similar bevel on the end of the upper semicircle. The two semicircles are connected by two lugs and two bolts at each end. The lagging is 2in. by 4in. in section, dressed with radial joints, and each piece is provided with three small iron clips on the lower side, which fitted over the flange of the ring and held the lagging in place.

New sleeping cars.—A new style of sleeping car, with private rooms opening into a corridor, has movable partitions so arranged that the upper berth is in one room and the lower berth in the next, each passenger having thus a room to himself, although the berths are wide enough for two persons travelling together. The berths are across the car, and by day the upper berths are closed and the lower ones form seats. Each room has a washstand. In another car all partitions fold up by day, forming a drawing-room car, with movable chairs and lounges. The berths and bedding occupy lockers against the side of the car and below the floor.

Magnetic separation of iron ore.—Owing to the recent great depression in iron and to the development of the great Bessemer bed of the Mesabi range, very little has been done to extend the use of magnetic separation, but experiments on a practical scale have been carried on at the Cranberry mines in North Carolina, with encouraging results. At these mines there is an excellent Bessemer ore, non-titaniferous, comparatively cheaply mined, partly in open cut and partly in tunnel, with good transportation facilities, and with a "run-of-mine" averaging about 42 to 43 per cent. of metallic iron. The greater portion of this iron is in magnetic oxide, Fe_3O_4, but from 5 to 11 per cent. is present as FeO in hornblende. Should the total output be crushed and magnetically separated, this FeO would be lost in the tails, and it becomes a question of considerable importance to decide when to save the hornblende and when to sacrifice it. The ore before shipping is passed over bar-screens having 1½in. openings, and what goes through, along with any clay from the open cuts which shows much ore in small pieces, is washed in a log-washer, in which it is freed from clay and very fine rock. A revolving screen on the washer-shaft separates the washed stuff into four sizes, viz.: (1) coarser than 1¾in. round hole, which is hand-picked; (2) between 1¾in. and 1¼in. round; (3) between 1¼in. and $\frac{3}{16}$in. round, which two sizes are treated separately on two Wenström separators; and (4) finer than $\frac{3}{16}$in. round, which is washed by a stream of water to a revolving magnet. The heads from this magnet are again divided by a revolving screen—8 holes per inch, of No. 18 wire—the rejections—"shot"—going to the furnace, and that passing through—"dust"—being sold. As the fines screened from the shipping-ore have not generally furnished enough clean ore to run the furnace, the deficiency is made up by crushing, in a Buchanan crusher, mixed rock and ore thrown out from the shipping-ore and picked out from the old dumps. This material, after crushing, goes through the washer and separators, with the fine from the mines. In one month 920 tons of ore from the crusher and 947 tons of "dirt" from the mine, or a total of 1867 tons, were sent to the washer and separators. From this was recovered 1029 tons of "clean ore," averaging 45 per cent. of metallic iron, 47 tons of "shot," averaging 55 per cent. of metallic iron, and 113 tons of "dust," averaging 63 per cent. of metallic iron; also 271 tons of tails and 406 tons of fines washed away—by difference—averaging together less than 20 per cent. of metallic iron. The conclusions arrived at are as follows:—(1) Emphasis should be laid upon careful washing, screening, and sizing rather than upon fine crushing; and (2) each size of material should be concentrated separately upon suitable magnetic separators, giving as a total result a Bessemer concentrate averaging from 50 to 60 per cent. of iron, and of a size sufficiently coarse for furnace-burden without other mixture.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THE coal trade during the past week has been in a state of great activity. The shipments exceeded 80,000 tons. Stems are generally well filled, and certainly for the next week or two the briskness will be well maintained. A large amount of tonnage is in both docks. The s.s. Idar commenced loading Monday morning, and sailed this morning with 6190 tons of coal. The s.s. Imaum and several other large steamers are due shortly. The collieries of the district are well employed. The tin-plate market is dull. Pitwood is firm at last week's prices. An improvement has taken place in the quantity of iron ore imported as compared with previous weeks. The activity reported last week in the ship repairing trade is well maintained.

Prices ruling on 'Change to-day were as follows:—Coal, best steam, 8s. 6d. to 9s.; seconds, 8s. to 8s. 3d.; best house coal, 10s. 6d.; dock screenings, 5s. to 5s. 6d.; colliery, small, 4s. 6d. to 4s. 9d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 6d. Pig iron: Scotch warrants, 46s. 7d.; hematite warrants, 47s. 8d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 7½d. prompt; Middlesbrough hematite, 45s. 8d. Steel: Rails, heavy sections, £4 10s. to £4 15s.; light ditto, £4 15s. to £5 10s.; tin-plate bars, £3 17s. 6d. to £4; Siemens tin-plate bars, best, £4, all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. 3d.; Siemens coke finish, 9s. 6d.; ternes, per double box, 28 by 20c., 21s. to 22s. Pitwood, 15s. 9d. London Exchange telegram: Copper, £41 6s. 3d.; Straits tin, £59 12s. 6d. Freights firm.

WEATHER AVERAGES.—Some useful modifications have been made by the Meteorological-office in the monthly means of the barometer and temperature which are now given for the twenty-five years, from 1871 to 1895, and the rainfall values for thirty years, from 1866 to 1895. An addition has also been made showing the absolute maximum and minimum temperature recorded during the month, for the twenty-five years, stating the years in which such extremes occurred. The mean number of hours of bright sunshine are also given, for the period of fifteen years, from 1881 to 1895, for the stations in the United Kingdom at which the amount of sunshine is regularly registered. The new values show that in January the average barometer is highest at Jersey, where the mean is 30·01in., and the readings are lowest in the north of Scotland, the mean at Sumburgh Head being 29·68in. This shows very plainly that the prevailing winds in January are westerly. The average highest maximum temperature is 49 deg. at Valentia, while at Spurn Head, where the lowest mean maximum occurs, the reading is only 41 deg. The highest average night minimum occurs at Valentia, where the mean of the lowest readings does not fall below 40 deg., and the place with the lowest average night reading is Cambridge, with 31 deg. The absolute maximum temperatures range between 51 deg. and 59 deg. over the entire area of the British Islands, and they occur in very different years. The highest individual reading is 59 deg., at Nairn and Cambridge. The absolute lowest readings vary to a much greater extent, the lowest being minus 4 deg. at Wick in 1881, and the highest 25 deg. at Scilly in 1894; whilst the lowest reading at many of the Irish stations was 20 deg., which occurred in 1894. The wettest station reporting to the Meteorological-office, for January, is Valentia, where the average rainfall is 6·31in.; and the driest is Spurn Head, where the average is 1·38in. The maximum amount of sunshine is 71 hours at Jersey, the minimum being 26 hours in London.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

A FURTHER advance in the condition of trade is observable, and Messrs. Brown and Freer, of the Leys Ironworks, one of the marked-bar firms, quoted their prices this afternoon:—Round and square rods, ½in. and $\frac{7}{16}$in., £7 for ordinary qualities, £8 for best, and £9 for best best; ⅜in. sizes were £7 10s., £8 10s., and £9 10s., according to quality; $\frac{5}{16}$in., £8, £9, and £10; ¼in., £8 10s. for ordinary, £9 10s. best, and £10 10s. best best. No 4 B.G. were £9 ordinary quality, £10 best, and £11 best best; while No. 5 B.G. was £9 10s., £10 10s., and £11 10s. respectively; and No. 6, £10 £11, and £12. Angle iron the same firm quoted £7 10s. to £8 10s., according to brand; T iron, £8, and half-rounds and ovals £8 to £9, while best rivet iron was £8.

Pig iron exhibits additional improvement on the week, but prices have not yet fully recovered, and some buyers report that they have placed orders at 1s. 6d. and 2s. per ton less than smelters quote. Northampton pigs—forge sorts—are priced at a minimum of 40s. to 41s. as the actual selling figures, but sellers ask 42s. to 42s. 6d. Good foundry iron is 44s. to 45s. Derbyshire forge pigs are 41s. to 42s. in actual business, and foundries 45s. to 46s. Hematites are 56s. 6d. to 57s. 6d. for West Coast forge sorts, and 58s. 6d. to 60s. for foundry.

Much satisfaction is expressed in the Midland district at the probable expenditure of £20,000,000 sterling on British naval requirements, and also at the heavy expenditure intended by Japan under the same head, a great part of which is certain to be allocated to this country. It is stated that orders for the ten men-of-war, by which the Japanese navy is to be increased, will definitely be placed with British shipbuilders, and that four of these battleships are each to have a tonnage of 15,150 tons, which will be 2000 tons in advance of the largest vessels possessed by any other naval Power than our own. The plant and machinery required for the two new Government dockyards to be established in Japan are also, it is rumoured, to be purchased from British engineering shops. Confirmation is also to hand this week of the intention of the Argentine Government to early expend £2,000,000 in this country on arms and ammunition and other war material.

Much discussion took place on Wolverhampton and Birmingham Exchanges this week concerning the report of the continental deputation of the British Iron Trade Association and allied bodies. Complaint was made that it was a colourless document, too much having been made of railway rates and rolling mill equipment, and too little of the wages matter. It is believed that the men objected to comparative wages statistics being published, and hence the incomplete nature of the report on this point. Wages details are, it is true, given in the appendix, but no attempt is made to contrast them with English wages.

Engineers who construct tube-making machinery are well engaged. Samuel Platt, Kings-hill, Wednesbury, are very busy on plant for machining seamless steel boiler and cycle tubes from start to finish. Their machinery begins operations by boring the ingots and reducing them by rolling; the ingots being cut with hot saws as they are extended in length. Several times during these operations they have to be put into various heating furnaces. They are then passed on to different descriptions of draw-benches, according to whether they are to finish for boiler or cycle tubes, and are passed through the annealing furnaces until they leave the benches as finished tubes ready for cutting off into lengths. This firm make machinery not only for seamless steel tubes, but also for lap-welded tubes, boiler tubes, and copper tubes—in fact, there is scarcely a tube firm in the country with whom they have not connections. Their business has been established forty or fifty years. The firm build also nut and bolt-making machinery, complete plants of which have been supplied by them to China and Japan, one of these complete plants being for the Chinese Government.

The wrought iron and steel tube makers, in the Wednesbury District more particularly, are this week informed that the Government Telegraph Authorities are considering the advisability of adopting metal poles for the construction of telegraph lines instead of the timber ones now in use. The particular pole which is believed to find favour with the authorities is a corrugated galvanised one which has been lately patented in this country and abroad, and which is said to be practically indestructible.

Engineers and machinists learn with pleasure that Sir Salter Pyne, C.S.I., who is again in this country on a brief visit from Afghanistan, intends to purchase on this occasion machinery and plant for the establishment of an ammunition factory at Cabul. Already the Ameer's factories have reached the full capacity of the present cartridge machinery, and 10,000 Martini cartridges and 10,000 Snider cartridges are turned out daily, besides field guns and rifles. The aggregate factories now cover an area of a third of a mile long by 200 yards wide, and 2000 hands, or 7 per cent. of the population of Cabul, are employed. The production of the Mint has increased to 120,000 coins per day, and electro-plating has lately been added to the previous industries.

The light railways question continues to be discussed amongst engineers here with much animation. In a communication which Mr. C. T. Sharp, consulting engineer, Birmingham, has just made on the subject, he insists that the Government should be called upon to construct and work the lines, and contends that, if the routes were judiciously selected, there would be no question that the Government would get their interest on the small capital absorbed.

The Bessemer basic steel manufactured by the Staffordshire Steel and Ingot Iron Company, Wolverhampton, has just been reported upon by Professor Ewing, F.R.S., of Cambridge. He remarks upon the material:—"Its permeability, especially for inductions such as are used in dynamo magnets, is remarkably high. The B.H. curve is almost coincident with a curve for 'pure iron,' given in the 'Proceedings' of the Royal Society for June 16th, 1892. Most forgings and steel castings give results which lie considerably below the 'pure iron' curve, and I have never before tested a specimen which approaches it so nearly as this does. The hysteresis losses are small in comparison with those generally found in forged metal; it is only in the best samples of thin transformer plates that I have found less. The general result of the test is to show that in regard to magnetic quality this is a first-class material for dynamo magnets."

I regret to have to announce the death, at the end of last week, of Mr. Clement Crowther, of Greenhill, Kidderminster, Chairman of Messrs. Knight and Crowther, the well-known tin-plate manufacturers. Previously to the constitution of the company, Mr. Crowther carried on the Stour Vale and Falling Sands Works at Kidderminster, and the Cookley Works at Brockmore. Mr. Crowther also carried on business as the Central Iron, Steel, and Tin-plate Co., at Kidderminster, and was largely interested in various other commercial undertakings. He was about sixty years of age and unmarried.

Mr. James Mansergh, C.E., has deposited his parliamentary estimate of the expense that will be incurred by the Birmingham Corporation in the event of their great Water Bill for next session receiving the sanction of Parliament. The total cost of the whole of the proposed works, including the purchase of the necessary property, and allowing for contingencies, is set down at £110,000. Of this sum the works connected with the proposed deviation of the authorised aqueduct will cost £103,090, and the proposed 7 furlongs 4 chains of railway will cost £6910. With this estimate the Town Clerk has lodged a declaration "that the rates and revenues of the Corporation, for which the moneys for making the works proposed to be authorised will with other moneys become chargeable, will amount to £231,000."

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester. — The market is gradually resuming the strong position which was somewhat shaken at the commencement of the year by the generally unsettled outlook, and although perhaps just for the immediate present the situation is not quite so satisfactory as it might be, the prospects for the future are regarded confidently. A steady, active trade, with advancing prices, is talked of in most quarters, and there is a disinclination amongst makers and manufacturers of iron to enter into anything like heavy forward engagements far ahead. The downward tendency of prices in outside brands of pig iron has not only been completely checked, but during the last week or ten days there has been a recovery of quite 1s. per ton upon the minimum figures which sellers in some instances were previously taking. Some classes of finished iron, such as sheets, in which there has been rather a severe relapse, are also recovering strength, whilst the volume of business all through is steadily on the increase.

There was a good average attendance on the Manchester Iron Exchange on Tuesday, with a fair amount of inquiry stirring and prices firm, the improvement reported last week being fully maintained. In pig iron moderate transactions are being put through, and for local and district brands, which were unaffected by the recent depression in the market, makers' quotations remain at 46s., less 2½, for No. 3 foundry Lancashire; 45s. 6d. to 46s. 6d. net cash for foundry Derbyshire; and 41s. 6d. for forge to 43s. 6d, for foundry Lincolnshire, net cash delivered Manchester. For outside brands of pig iron coming into this market prices are stronger, foundry Middlesbrough not being quoted under 45s. 10d. to 46s. 1d. net cash, delivered Manchester, with Eglinton fetching 47s. 3d. to 47s. 6d. net prompt cash, delivered Lancashire ports.

In the manufactured iron trade a steady business is reported generally, especially in bars, for which makers are securing new orders which are more than sufficient to keep them fully going, and they are firm at £5 10s. for Lancashire to £5 10s. and £5 15s. for North Staffordshire bars, delivered here; sheets are if anything not quite so firm as they were recently, and £7 10s. now represents about the average selling figure, but inquiries are again beginning to come forward more freely. Very little business is stirring in hoops, the orders now being secured by makers being scarcely sufficient to keep mills running two days per week; but Association list rates remain at £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, delivered Manchester district, and 2s. 6d. less for shipment.

Nut and bolt makers report a considerably enlarged demand for all descriptions of goods, with a stiffening upon recent selling rates in some instances, although there is no quotable advance in prices.

In the steel trade the only change to note is that hematites—although meeting with no appreciably increased demand in this district—are decidedly stronger in price, some special brands being quoted 57s. to 57s. 6d., less 2½, with 56s. about the minimum figure for ordinary foundry qualities, delivered here. Pending the settlement of the shipbuilding dispute, steel boiler plates are still obtainable at £6 to £6 5s. for immediate delivery in this district.

A fair business comes forward in the metal market, especially in tubes, but there has scarcely been so much doing in rolled metals as of late. Inquiries are increasing for all descriptions of fittings in connection with locomotive work, and a few fairly good orders have been booked, whilst it is reported that others are coming upon the market. List rates are well maintained, and the improvement in copper is tending to harden the market, the opinion generally being that any further change in prices will certainly not be in a downward direction.

The returns of the Steam Engine Makers' Society fully confirm those which I gave last week from the Amalgamated Society of Engineers. As, however, the Steam Engine Makers' returns were made up before the men had got into full work again after the holidays, it is difficult to give any precise estimate of the percentage of unemployed members on the books, except that it has now got back to what it was prior to the holidays. The reports received from the various districts connected with the Society as to the state of trade are of a very encouraging character; most branches are experiencing a steady improvement, establishments generally being well employed, whilst a special feature has been the increased activity in the Government dockyards.

The reports which I gather on 'Change from the principal representatives of the engineering trades also continue very satisfactory, new work in most departments coming forward freely. The boiler making and locomotive building industries are steadily improving; machine tool makers are in most cases securing a large weight of new orders, and stationary engine builders remain in much the same satisfactory position as they have been for some time past.

There have been reports during the past week on the Manchester Exchange, emanating from apparently well-informed quarters, to the effect that Messrs. Harland and Wolff, of Belfast, have in contemplation the establishment of an extensive shipyard on the banks of the Mersey, near Liverpool, and that land has actually been taken for this purpose. One reason assigned for Messrs. Harland and Wolf extending their operations to Liverpool, is that for many years past it has been serious ground of complaint, that in the case of vessels putting into Liverpool for repairs, application has to be made to the Mersey Dock and Harbour Board for a dock, and not infrequently the vessel is assigned to a dock miles away from the engineering shops of the firm who may have the repair in hand, the particular dock to which the vessel may be sent being, of course, altogether at the discretion of the Board and regulated according to their own convenience. If the reports are correct with regard to Messrs. Harland and Wolff's intentions, a very welcome stimulus will be given to the shipbuilding industry of the Liverpool side of the Mersey, which for some years past has been steadily declining.

For a long time past there has been considerable friction between the employers and workmen in the engineering trades of the Bolton district on the question of overtime, and I understand the men actually threatened to refuse altogether to work overtime, unless some satisfactory understanding could be come to with the masters. During the last two months a number of conferences have been held between representatives of the employers and the men, with a view of coming to some satisfactory arrangement, not only with regard to overtime, but also in order to arrive at a settlement of other minor questions, which from time to time have arisen. These conferences have at length resulted in an amicable arrangement being come to. I am not yet in possession of the official resolutions adopted, but I understand that the agreement with regard to overtime is practically to the effect that, except as regards breakdowns and repairs, where, on new work only, any workman has made in four successive weeks, more than ten hours' actual overtime per week, or more than forty in the aggregate, he shall not be called upon to work for the ensuing two months more than ten hours' actual overtime in any week. Other questions were discussed in a friendly spirit, and upon one matter, in which some of the machine fitters are rated under the standard rate, the masters conceded that they were entitled to an advance, and also the application of the smiths' strikers to be rated for all night-work the same as the smiths, viz., time and a-half.

For some time past the United Alkali Company, which is a large producer of copper, has been carrying out a series of experimental tests, with a view of manufacturing manganese alloys possessing high tensible strength, hardness, and ductility, which should meet the increasing demand for such metals in all branches of engineering work. As a result of these experiments, which have been very successful, the company is now making a high-class bronze, which fully meets the above requirements, whilst it also possesses high resistive power to the corrosive action of chemicals. The company has also gone into the question of amalgamating other metals, and is now manufacturing a special alloy for reducing friction and wear and tear in machinery.

In the coal trade only a moderate business is reported, with pits in many cases not working above four to five days per week. House-fire qualities are perhaps in somewhat better request, but there is no push of orders, and with supplies plentiful, prices are not more than maintained at late rates, averaging 10s. to 10s. 6d. for best Wigan Arley; 9s. to 9s. 6d. for Pemberton four feet and seconds Arley; and 7s. to 7s. 6d. for common house coal, at the pit mouth. The excessive supplies of steam and forge coals keep prices extremely low, not averaging above 6s. at the pit mouth for inland sales; whilst for shipment, surplus supplies continue to be offered at as low as 5s. 6d. per ton at the pit mouth, representing about 7s. to 7s. 6d. delivered ports on the Mersey. Engine fuel moves off fairly well, owing to the rather limited output of slack at many of the pits, and best sorts remain at 4s. 6d. to 5s.; with common descriptions 3s. to 3s. 6d. per ton at the pit mouth.

Considerable alterations are now being carried on in the Manchester Coal Exchange, with a view of increasing the accommodation of members, and the Committee in their annual report issued this week express the hope that when these were completed the comfort of the members would be fairly met, and also that the premises may be capable of earning larger revenue from other sources. The report adds that the Exchange continues to make steady progress financially, and that the number of members is fully maintained. The financial statement shows the income for the past year amounted to £593, of which £494 is represented by subscriptions, and the expenditure to £479, leaving a balance of profit of £114 to be carried forward. The general balance account shows the assets of the Exchange to be now valued at £1510, of which £1286 is invested in railway stock; with furniture, fittings, and goodwill accounts put down at £205, the balance being cash at bankers' and sundry accounts owing. The annual general meeting is fixed to take place on Tuesday, February 4th, and Mr. John Tomlinson, of Darwen, has been unanimously nominated president; Mr. Isaac Mosly, of Doncaster, as vice-president; and Mr. R. Peters, of Tyldesley, for re-election as treasurer. The two auditors, Mr. E. S. Wigan and Mr. H. Nield, are also nominated, without opposition, for re-election; but a ballot will be required for the Committee, there being five nominations for four vacancies.

Barrow.—There is a much stronger and more buoyant tone in the hematite pig iron trade of this district, and business is improving on local and general account. Makers are very well sold forward. Several furnaces have been ready for some time to put on blast so soon as an improvement in trade justified such a step, and it is now proposed to light some of these, as it is found that the production is not likely to be equal to the demand. Prices have improved to 47s 6d. for merchants, net cash sellers, and buyers offer ½d. less; makers' iron is qnoted at 40s. to 49s. per ton, and only forward deliveries can be negotiated. During the week 106 tons of iron have gone into warrant stocks, which now represent 297,978 tons, or an increase of 8803 tons since the beginning of the year.

Iron ore is in steady demand at about 10s. per ton net at mines for ordinary sorts. There is a large importation of Spanish ore into the district.

Steel makers are busy. There is a brisk demand for steel rails, which are quoted at £4 15s. for heavy sections, and makers are well booked forward. There is also a good demand for plates, and some good orders have been booked during the week. Billets, hoops, and heavy castings, have been largely ordered lately, and prospects all round in the steel trade are very good.

Shipbuilders and engineers have booked no new orders, but are expecting some from various sources, and in the meantime they are paying great attention to the important Admiralty contracts in hand.

Coal and coke are in better demand, and prospects of a better trade are presenting themselves.

His many friends will be glad to learn that Mr. James M'Kechnie, now engineering manager at the Naval Construction and Armaments Company's Works, at Barrow, has had his services to the Spanish Navy most fittingly acknowledged. The King and Queen Regent have conferred upon him the Commandership of the First Class of the Royal Order of Isabel la Catolica, which is a very ancient order, having been established when Spain had extensive colonial possessions on the Spanish main. In distinction it ranks next to the famous Golden Fleece and Calatrava, and the insignia is a gold Maltese cross with a star and a green laurel wreath. The motto of the order is "A la leultad acrisolada." Mr. M'Kechnie, it is scarcely necessary to explain, while engineering manager at the Nervion Works, at Bilbao, designed and constructed engines for three magnificent belted cruisers of 20¼ knot speed. Her Majesty the Queen of England has granted to Mr. M'Kechnie permission to accept and wear the decoration within the British Empire.

Shipping is not yet briskly employed, 6515 tons of pig iron and 6038 tons of steel were exported during last week from West Coast ports, as compared with 8130 tons of pig iron and 3516 tons of steel in the corresponding week of last year, being a decrease of 1615 tons of pig iron and an increase of 2522 tons of steel. The aggregate shipments this year to January 18th were 20,511 tons of pig iron and 29,186 tons of steel, as compared with 13,343 tons of pig iron and 19,120 tons of steel in the corresponding period of last year, an increase of 7168 tons of pig iron and 10,066 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

A STEADY business has to be reported in the South Yorkshire coal trade during the past week; still, complaint is freely heard on all sides of the limited wages to be earned. This is mainly due to the accumulation of stocks. The general condition of the coal trade is clear enough. It only requires a sharp spell of frosty weather to put it in an excellent way. London and the South have been taking but a poor tonnage. This shrinkage cannot be put down solely to the competition of seaborne coal, as the shipments from Newcastle during 1895 showed a decrease of 557,917 tons. Hardly an average trade is done with the Eastern and other markets. Quotations remain about the same as last week. Best qualities of Silkstone coal are at 9s. to 9s. 6d.; secondary sorts, 7s. 6d. to 7s. 9d.; Barnsley softs, 8s. to 8s. 6d., and Flockton at similar prices. Thin seam coal only fetches 6s. per ton at the present time. The steam fuel industry is, as is usual in January, in a quiet condition. A fair amount of coal, however, is being forwarded to Grimsby, although only a moderate tonnage is sent to Goole. The demand on contract account is very good. The North-Eastern Railway are now taking a good supply. Prices in the open market are 6s. 6d. to 7s. 3d. per ton, according to quantity and quality. A better business is also being done by the Barnsley thick seam pits, as well as the thin seam collieries, with the Yorkshire woollen districts, although the request from Lincolnshire is only moderate. Small nuts sell at 5s. to 5s. 6d.; good screened slack, 4s. 3d. to 4s. 6d.; and ordinary pit slack, 2s. 6d. per ton. Smudge can be procured in small quantities at 1s. 6d. to 1s. 9d., while larger tonnages are obtainable at 1s. to 1s. 3d. per ton. On the whole the coke trade is in a fair condition. The output is big and stocks are somewhat decreasing. Derbyshire is taking an average amount, and North Lincolnshire is requiring some 600 tons a week. The quotations run about 8s. to 10s. per ton.

In the heavy industries the New Year has opened very favourably in nearly all the departments. The political troubles in South Africa and other countries do not seem to have had the adverse effect at first anticipated, although it may be evident before long. The three firms engaged in the manufacture of armour-plates are extremely busy on orders for the British Admiralty. The war scare, which was prominent before the eyes of the world a few weeks ago, while affecting business in several departments, improved to a considerable extent the modern branches of local industry. The orders for shot and shell placed by the home Government do not in any way synchronise with those for armour-plates. The American Government have just given an order to a United States steel house for the manufacture of £50,000 worth of shells of a similar description to one of the Sheffield patterns, with the additional welcome news that there will be more to follow shortly. Two of our local houses have received orders from the British Government for shell. Messrs. Thomas Firth and Sons, Norfolk Works, are making 200 6in. armour-piercing shells, the order for which was settled before the late "scare." The Hadfield Steel Foundry Company is also in receipt of orders for shells. Those given to Sheffield, however, must be but the beginning of what the authorities will yet have to place.

The steel trade has been particularly brisk since the beginning of the year—one portion so brisk that it may be specifically mentioned. We refer to the demand for cycle steel. The extraordinary increase in cycles, owing to the pastime being taken up by females, is very clearly indicated in the larger value of orders received by firms who make a distinct speciality of that grade of steel. They inform us that not only is the quantity much larger than it used to be, but the quality of the steel demanded is continually getting higher. The great necessity of the machine, trustworthyness of material, is the cause of this call for the finer classes of steel, and it is expected that the business will be a continually advancing one. A vigorous effort is being made to localise the cycle manufacture in Sheffield, where it might have been to-day a most important trade. At one time the Stanley machine, made at the Stanley Works, Sheffield, had a great run, and if the swivel handle, which was a Sheffield invention, as applied to the cycle, had been patented at the time, the business would no doubt have assumed enormous local dimensions, and a great fortune would have been made out of it.

In the iron market the outlook is particularly encouraging, with prices very much steadier. There is a welcome absence of speculation in this district, and most of the orders given out have been of the hand-to-mouth character. Hematites are selling in this city at 57s. for West Coast and 54s. for East Coast, with common iron at 40s. per ton. Siemens-Martin and Bessemer are reported in better demand, while files and tools find ready purchasers. Makers of railway material specialities, such as axles, tires, springs, buffers, &c., are full up with work. Sheep shears have been in better request since the season—namely, the end of October—closed. The increase has been larger than has been the case for five or six years, and the improvement is pretty general all round.

In the cutlery and silver trades business is very plentiful. Several large orders for the complete fitting up of a few palatial hotels with silver plate will cause many men to have good employment for some months to come. The cutlery trade has not been so active during the present month as it was before Christmas, although it is a considerable increase on the trade done in January of 1895. Grinders are rather scarce at the present time. The adverse effect of the McKinley tariff caused a considerable number of artisans to be thrown out of employment. They drifted into other industries, and, when tariff troubles ended, did not come back, and their absence is now getting more keenly felt.

The Wigan Coal and Iron Company has leased from the Duke of Newcastle a large extent of ground, extending to 30,000 acres, it is said, to work the coal underneath the land in what is familiarly known as the Dukery District. The name comes from the fact that at one time five Dukes lived in or about the Sherwood Forest. The position of the new pits is said to be about midway between the Great Northern Railway and the new Lancashire, Derbyshire, and East Coast Railway, about three miles from Tuxford. The place is near Houghton Warren, and is one of the most picturesque parts of that delightful land. The first pit will be sunk at Bevercotes. The company, it is said, intends to work the coal there on a great scale—in fact, no other manner of coal-getting will pay in these days. The output will be some 2000 tons a day, and it is intended to extend a spur line from the Great Northern Railway, and probably the New Lancashire, Derbyshire, and East Coast Railway also, to serve the new colliery. The enterprise will make a remarkable change in that district, quite as remarkable as has been done at Cadeby, where the pleasant slopes on the banks of the Don, overlooking Conisbro' Castle, one of the scenes of "Ivanhoe," have been changed into a bleak coal country. That was inevitable with Denaby Main so close at hand, but no one anticipated that the Land of Robin Hood would ever be given over to railways, or, what is grimier still, become the colliery home of a Lancashire coal and iron company.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE political situation having become more quiescent, and there being an expectation that though the voting last week in connection with the Clyde-Belfast difficulty was abortive, the stoppage of work will last but a few days longer, the iron market has been very strong this week, and the improvement is progressing satisfactorily. A more confident tone is apparent, and a disposition is shown among the consumers to buy for forward delivery; indeed, a considerable number of inquiries have been received for pig iron, mostly from home users, and there is beginning to be more life as regards the demand from abroad, for it is the general opinion now that the war scares being over, prices will advance, and that those who wait will have to pay higher rates for spring delivery. As yet, the increased number of inquiries has not resulted in much increase in the actual orders placed, because producers are not prepared to commit themselves further ahead than the next six weeks or two months, by which time the spring trade will have fairly set in, and rates more favourable to the seller will in all probability prevail. On the whole, consumers are readier to buy than producers to sell, and the prospects are generally encouraging.

Pig iron prices have this week been further advanced—6d. in the case of No. 3 Cleveland and hematite, and 3d. in forge pigs—and Cleveland warrants, which on the 8th inst. were down to 36s. 2d., cash, have gained 1s. 5d. since then, of which 6d. has been recorded since Monday, and all that was lost in prices through the disturbed political relations which became acute in the middle of December, has been recovered. The improvement in demand is now of a *bona fide* rather than a speculative character, and in this it differs from what was experienced in the autumn, and is more likely to be kept up. There is more life in the pig iron consuming industries, and that itself affords ground for expecting an increasing pig iron trade during the spring. No. 3 Cleveland pig iron was sold early this week at 37s. per ton for immediate delivery, but the general price has been 37s. 3d., and a considerable number of sales have been made at this figure for January delivery, while 37s. 6d. has been paid for February, and 37s. 9d. for March. Buyers of No. 3, for spring delivery, at 37s. 6d. there have been in plenty, but sellers, both makers and merchants, have not been prepared to accept that, as they have no doubt that they will realise more. No. 1 Cleveland pig has been advanced to 38s. 6d. A brisker demand has sprung up for the lower qualities of Cleveland pig iron, but these are very scarce, as few of the furnaces are turning out any. It is a long time since the quality of the iron made at the Cleveland furnaces was so uniformly good, and in this they have been favoured by the open winter, which has allowed of a drier coke being used. Those who need forge pig iron now have much difficulty in getting it, and for No. 4 foundry have to pay 36s. 9d., while for grey forge 36s. 3d. has been given, and scarcely any of the latter can be had under that figure. White iron is at 35s.

A good deal of business has been done in East Coast hematite pig iron during the last few days, and the price has been advanced fully 6d. per ton, mixed numbers being quoted at 46s. for early f.o.b. delivery, and some of the leading brands cannot be had at that. The price of Spanish ore continues steady, and has not fallen with the easier rates of freight, as might be expected. Average Rubio ore is at 12s. 6d. per ton, delivered in the Tees. Mr. Joseph Angus, who for several years has been assistant manager at Messrs. Cochrane and Company's Ormesby Ironworks, Middlesbrough, has been appointed manager and engineer at the Claylane Iron Company's furnaces at Southbank.

The stock of Cleveland pig iron in the public warrant stores is accumulating less rapidly this month than was the case in December. On Wednesday night the stock held by Messrs. Connal and Co. was 178,416 tons, or 6716 tons increase this month.

The demand for finished iron and steel is improving. Especially is this the case with respect to steel rails and railway material, this department being undoubtedly in a very healthy condition; the works are in full operation, and orders are booked by manufacturers which, it is said, will keep them going during the greater part of the current half-year. Not for six years has there been such an active demand for rails as there is at present, and the price of heavy steel rails is fully maintained at £4 15s. net at works. Chairs and sleepers are also in more request, and there has sprung up also a good business in structural iron and steel, especially for bridge work and girders for abroad. The bar manufacturers, who have had a more prolonged experience of the depression than most of those engaged in the iron and steel trades, now speak more favourably of their business, orders are more numerous, competition less keen, and the price is stiffer, though it is not as high as it was in December, about £4 17s. 6d., less 2½ per cent. at works, is the general rate. The plate makers have been affected by the stoppage of work on the Clyde and at Belfast, and have had difficulty in getting specifications from consumers to keep their establishments fully going. In consequence of this they have had to look out for orders elsewhere, and to secure them have had to accept reduced prices. This explains the drop in prices as compared with December. Steel ship-plates can be got at £4 17s. 6d., less 2½ per cent. at works, if the order be for a fair quantity, but manufacturers ask 2s. 6d. more where the lot required is a small one. The same may be said of the angle trade; steel angles are at £4 15s., and iron angles at £4 12s. 6d., both less 2½ per cent. and f.o.t. The prospects for both branches are good, seeing the revival that is taking place in shipbuilding, partly owing to the work in hand and promised from the British Admiralty and other Governments. The demand is more for steel than iron plates and angles.

Engineers are experiencing fair improvement in their business, and are advancing their prices. The officials and workmen of the Stockton Malleable Iron and Steel Co. on Saturday made a presentation to Mr. Fred. G, Mills, late manager of the steel works department, on his leaving to take the management of the works of the Glasgow Steel and Iron Co. at Wishaw. A presentation was on Saturday made to Mr. Edward Wann, who has been fifty years in the employ of the North-Eastern Railway—forty-one years as engine driver. He was born at Elswick, and at the age of twelve entered the railway shops at Gateshead as cleaner. After four years he was promoted to be engine fireman, and was occupying that position when the Queen opened the Central Railway Station and High Level Bridge at Newcastle in 1850. In 1855 he became driver, and has for the last twenty-five years run expresses between York and Edinburgh. On several occasions he has been selected to act as driver to various members of the Royal Family, including the Prince of Wales and the German Emperor. Messrs. Arnett Brothers have within the last few days commenced operations at their new bolt, nut, and rivet works at Middlesbrough. They intend to make a specialty of fish-plate bolts for railway purposes, and they are intending to put down at least eight machines. It is expected that a good trade will be done with London in rivets, as it is claimed that they can be delivered there at less than is charged for Staffordshire rivets.

The coal trade of Northumberland is slack, and scarcely any of the collieries can be carried on full time. For best steam coals 7s. 9d. per ton f.o.b. will now be taken, but that is for early delivery only, and more has to be paid where spring delivery is required, as the trade will then be brisk again. The accountants to the Conciliation Board have certified that the average realised price of all the Northumberland coal delivered during the three months ending November 30th last was 5s. 5·07d., which is below that of the previous quarter, and in fact is the lowest price known for several years. The colder weather is making the house coal collieries rather busy, but the winter has been a disappointing one for coalowners and merchants, and higher prices have not been realised. As there were so many miners who abstained from voting when the question was put before them as to the abolition of the Conciliation Board in the Durham coal trade, it has been considered that the result of the voting was inconclusive, and therefore another vote is being taken this week. Coke is in good request, and the price is maintained at 13s. per ton, delivered at the furnaces on Tees-side.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market was strong at the end of last week in consequence of the Clyde engineers having voted to return to work, and a substantial advance occurred in the price of warrants. Scotch iron lost about 6d. per ton at the beginning of this week owing to the adverse vote of the Belfast engineers, but the market has since been better, as it is held on 'Change that the engineers' dispute has too long influenced business, and is now practically decided. A large quantity of Scotch warrants have changed hands in the course of the week. A moderate business has been done in Cleveland and Cumberland iron.

It is reported that the ironmasters intend to reduce to some extent the output of pig iron, in order to prevent a further accumulation of stocks at their works. The requirements for the shipping trade have been so light that a steady increase in stocks was inevitable. On the other hand, it is pretty generally held that the production of iron at present low rates of fuel, and with a moderate outlay for wages, could scarcely fail to be remunerative in the end, were the masters inclined to invest their money in larger stocks, and wait for a favourable market. Since last week the output of ordinary Scotch pig iron has been reduced by about 600 tons per week. At the same time, there has been an increase of nearly that extent in the make of hematite. One ordinary furnace has been put out of blast at Glengarnock. There are now seventy-seven furnaces in operation in Scotland, compared with seventy-three at this time last year, and of the total, forty-two are making ordinary, thirty-one hematite, and four basic iron.

The values of g.m.b. and several other classes of iron are somewhat higher. The current quotations are as follow:—G.M.B., f.o.b. at Glasgow, No. 1, 47s.; No. 3, 45s. 6d.; Govan and Monkland, ditto, ditto; Carnbroe, No. 1, 47s.; No. 3, 45s. 6d.; Clyde, No. 1, 50s.; No. 3, 47s.; Calder, Gartsherrie, and Summerlee, Nos. 1, 51s.; Nos. 3, 48s.; Coltness, No. 1, 53s.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Carron, at Grangemouth, No. 1, 53s.; No. 3, 49s.; Shotts, at Leith, No. 1, 53s.; No. 3, 48s. 6d.

The shipments of pig iron from Scottish ports in the past week were 4367 tons, compared with 5080 in the corresponding week of last year. To the United States 35, South America 50, India 78, Australia 578, France 55, Italy 50, Germany 165, Holland 70, Belgium 130, China and Japan 340, other countries 105, the coastwise shipments being 2711, against 4230 in the same week of 1895.

In the malleable iron department there is an improving tone. Business is opening out fairly well, and the makers are now endeavouring to obtain the best rates that were current in the latter half of last year. They quote bars at £5, and angles £4 17s. 6d., less the usual 5 per cent. for payment in one month. There is a moderate business in sheets. The demand from South Africa, which had grown to be an important item in the business, has of late been necessarily interfered with by events at the Cape, but a revival and even an extension of the business in that direction is confidently expected. The steel trade is quiet, but there is full employment, and the prospects are satisfactory.

There is rather more doing in coals. The shipment from Scottish ports in the past week amounted to 125,962 tons, compared with 92,963 in the preceding week, and 113,229 in the same week of 1895. For some classes of coals the inquiry is improving for home consumption, but the output is so large that it is impossible to obtain better prices, the current figures being practically those last quoted in this correspondence.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

I AM now enabled to confirm the statement made last week that the Admiralty had placed an additional large order in the Welsh market for steam coal. Instead of 100,000 tons, as stated, the order is 110,000 tons, and has been apportioned as follows:—Hill's Piymouth, 10,000 tons; Standard, 10,000 tons; Dowlais, 20,000 tons; Lewis's Merthyr, 15,000 tons; Cambrian, 10,000 tons; Powell Duffryn, 25,000 tons; National, 10,000 tons; and Cyfarthfa, 10,000 tons. The prices range from between 9s. 9d. to 10s. 3d., net.

The steam coal trade is remarkably strong in the Cardiff district, as evidenced by the fact that the exports last week totalled 340,000 tons, or 80,000 tons more than those of the preceding week. For some qualities of steam there was a pressure, principally due to the stoppage of two collieries in the Aberdare-Hirwain district. A marked feature has been an improved French trade, dry coals being particularly in demand. Monmouthshire coal has also been strongly booked, and prices are quite 3d. per ton better for this class of coal than last week.

The great coal export of last week naturally told heavily on the railways, and the result was a "record week" for the Taff Vale. The total carried by this line of rail was over 300,000 tons of coal. Local statists point out that this is equivalent to fifteen million tons per annum. As it is, it was the largest quantity ever carried down in one week. The closest approach was in January, 1895, when the total carried down was 294,000 tons.

Up to the eve of my despatch the prospect of a good week's work on rail and at docks was fairly assured. Shipments are numerous, and the Cape, Bombay, and Monte Video figure well. One cargo for Bombay amounted to 7000 tons.

Mid-week prices remained firm, with an upward tendency for some qualities. On 'Change, Cardiff, quotations were as follow:—Best steam coal, 10s. 6d.; seconds, 9s. 6d. to 10s. 3d.; drys, 9s. 6d. to 9s. 9d. Small steam easier, best, 5s.; seconds, 4s. 3d. to 4s. 6d.; drys, from 4s. f.o.b. The spurt in Monmouthshire coal, as I have stated, continues; best, Cardiff shipment, is quoted at 8s. 9d. to 9s.; seconds, 8s. to 8s. 3d.

The coming on of something like winter weather has told upon house coal in regard to demand, though prices remain much about the same. Prices now are:—Best, 10s. 9d. to 11s.; No. 3 Rhondda, 9s. 9d. to 10s.; brush, 8s.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 8s.; through, 6s. to 6s. 3d.; small, 4s. 3d. to 4s. 6d.

Pitwood is at 15s. 9d., Cardiff. Patent fuel is rather weak at Swansea; better at Cardiff. Prices unchanged. Cardiff makers well booked ahead. For coke demand is increasing. Last prices, Cardiff:—Furnace, 12s. 6d. to 13s. 6d.; foundry, 15s. 6d. to 16s. 6d.; special, 19s. to 19s. 6d. Swansea prices:—Furnace, 12s. to 12s. 6d.; best foundry, 16s. to 17s. Swansea coal prices:—No. 3 Rhondda, 10s. to 10s. 6d.; No 2 Rhondda, 8s. 9d. to 9s. 6d.; best steam, 9s. 6d. to 10s. 6d.; anthracite, 8s. 9d. to 9s. 6d., and 11s. to 12s., according to quality. The coal trade at Swansea has little of the vitality which marks business at Cardiff. Last week the total shipment was below the average, only amounting to 28,630 tons. Destinations: France, Italy, Holland, Denmark, Portugal, Rio de Janeiro. The United States took 4879 tons.

The steel rail trade at Swansea is tolerably good. The depressed state of the tin-plate trade has told considerably upon tin bars at the chief works, Cyfarthfa, Dowlais, Ebbw Vale, Blaenavon. There is, however, an expectation that this class of trade will improve again. It may not be out of place to put into stock the overmake, as the Crawshays used to do with merchant bars. In steel rails there has been one fairly good cargo sent from Cardiff, the best that has been recorded for some time, 3726 tons for Kurachi. Imports continue noticeable. Large cargoes of steel bars continue from Harrington for Port Talbot, and 400 tons pig from the Grovesend Steel Company for Swansea. Ulverston also sent this week to the same destination 552 tons pig iron.

On 'Change, Swansea, this week, iron and steel prices were as follows:—Pig iron, Glasgow, 46s. 2d.; Middlesbrough, No. 3, 37s. 3½d.; hematites, 45s. 2d.; sheet iron and steel, £6 5s. to £6 10s.; Welsh bars, £5 5s. to £5 10s. Steel rails, heavy sections, £4 10s. to £4 15s.; light, £4 15s. to £5 10s. Bessemer steel, tin-plate bars, £3 17s. 6d. to £4. Tin-plates were not quoted, but it was understood that for large quantities figures ranged from 9s. 1½d. to 9s. 3d., f.o.b. Swansea. This was the quotation of the London metal market. In respect of shipment the trade is looking up again. Last week it amounted to 52,109 boxes, and 49,148 boxes were brought to stock, which now consists of 161,172 boxes.

Liverpool quotations, tin-plate, last week were slightly above those given by the London metal market. Bessemer, 9s. 4½d., 9s. 6d., 9s. 7½d., and 9s. 9d.; Siemens-Martin, 9s. 3d., 9s. 4½d., 9s. 6d., 9s. 7½d., 9s. 9d.; Siemens-Martin, I.C., 20 by 10, 13s. 4½d. to 13s. 9d.; ternes, 20 by 28, 17s. 6d. to 18s.; and better grades 18s. 3d. to 19s., all Wales, f.o.b.

At Briton Ferry trade has been very much like that of the previous week, the colliers only working half-time; but Baglan Bay, Vernon, Gwalia, and Earlswood, fully employed. The production of pig at Briton Ferry Works was about the average, and that of steel bar and ingots at Briton Ferry and at the Albion Works tolerably good.

An impression prevails in Swansea that an improvement in the trade is at hand. On Tuesday an important meeting was held in Swansea by the Tin-plate Makers' Association, with the object of "considering the question of promoting a company to provide new markets for tin-plates, by employing agents in China, Ceylon, Africa, Australia, and other countries, supplemented by sending out experts and machinery." At a previous meeting on the 17th of last month it was agreed that a company should be formed with a capital of £20,000 in £1 shares. At the meeting this week about 200 mills were represented, and, though private, it would appear to have given the necessary momentum to a movement calculated, in the opinion of the best judges of the situation, to improve trade considerably. The idea of the proposer is that 400 mills should join, the capital to be raised by annual contributions of £10 per mill, which would provide an income of £4000 for five years. Another meeting will be held next week, and weekly for a time. Cordial co-operation is, of course, essential to the success of the effort.

It is probable that the old Lodge Works, Llanelly, will re-start next week. The men have offered a concession of 10 per cent., and this is accepted.

A new jetty is decided upon for Pembroke Dockyard, and some of the chief officials from the Admiralty are to visit some time this month, to fix a site.

Enthusiastic meetings have been held during the week at Aberdare and Merthyr in order to devise some means of recognising in a practical manner the honour awarded by the Queen to Sir W. T. Lewis, Bart. It is expected that the whole of the mineral district will be united in getting up a substantial fund. The recognition is likely to take the form of a statue, in Sir William's native place, Merthyr.

The Great Western Railway continues much in evidence as regards Wales, and rumours as to changes and annexations are common. One of the last is "a probable coalition between the Great Western and Barry Dock," but I prefer waiting to see the fate of the Bill that will shortly be discussed in Committee before accepting any rumour of the kind.

Hopes are freely expressed that the shipbuilding dispute on the Clyde and at Belfast is coming to an end. The pig iron market in Wales has sensibly improved since the signs given of a turn of the tide.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE industrial position over here is, on the whole, satisfactory, although the employment at the works and mills is reported as moderate rather than brisk. The tendency of prices was a trifle less firm last week, but no doubt when more orders are coming in quotations will improve. For the present there is still much cause for complaint, especially where export trade is concerned, quotations leaving little or no profit.

In Silesia both the blast furnace works and the rolling mills are in fair activity, and tolerably good prices have been realised, those for bars and girders being, on an average, M. 20 p.t. higher than at this time last year. The business in tubes is particularly lively. Reviewing the position of the Silesian iron industry during the year that is now past, it appears that most branches have pretty favourably developed in the last two quarters. Silesian iron trade is always more or less dependent upon other German iron markets, especially that of Rheinland-Westphalia, which is much more favourably situated with regard to costs of production and means of conveyance. On the other hand, Silesian export business, especially to Russia, is of considerable importance to the German iron market in general; the rising of the iron industry in Russia, therefore, causes some uneasiness in iron circles, as Russian consumption in iron and steel is enormous. With regard to changes in quotations, basic price for best merchant bar was, in the beginning of 1895, M. 120 p.t., free Breslau stores; in April, M. 125 p.t. was quoted; in August, M. 135 p.t.; and at the end of September, M. 135 p.t. was the price asked. Plates and girders have met with a similar improvement.

	Beginning of 1895.	March—April.	End of 1895.
	Mark, per ton, free Breslau.		
Plates	140 to 145	140 to 150	145 to 155
Girders	120 to 122	120 to 125	125 to 145

There is still very little speculation on the Austro-Hungarian iron market, but a fair number of inquiries, chiefly on local account, have been coming in upon the week, and makers report themselves pretty well off for new work generally. Present quotations are, for common forge pig: 45fl. to 46fl. p.t.; grey, ditto, M. 48fl. to 51fl. p.t.; Bessemer, 48fl. to 51fl. p.t.; Bessemer and Styrian ingots, 78fl. p.t.; Styrian bars, 105fl. to 112fl. p.t.; girders, 106fl. p.t.; heavy plates, 165fl. p.t.; tank plates, 130fl. p.t.; steel plates, 140fl. to 160fl. p.t., free Vienna. Throughout last year the condition of the Austro-Hungarian iron market has been a trifle weak, but was, all things considered, more favourable than in 1894. The business done in structural iron was particularly good, and so was the demand for most articles of railway material, while the employment in the bar trade left much to be desired. Prices were anything but firm, owing to the generally depressed tone which prevailed on most iron markets during the first quarters of 1895, and also because German competition was very keen, rendering it impossible for Austrian makers to sell their articles at remunerative prices. The pig iron trade was, on the whole, better situated than the malleable iron business, for, though quotations were rather low, there was much firmness exhibited. Prospects for the development of the Austro-Hungarian iron industry in 1896 are generally considered as favourable. Prices were, in florins, per ton:—

	1895.	1894.	1893.
Styrian forge pig, at works	46 to 47	46 to 47	47·50 to 48·50
Styrian bars, free Vienna	105 to 112·50	107 to 115	115 to 125
Bohemian bars, free Vienna	102 to 107·50	107 to 115	111 to 112
Girders, free Vienna	106 to 110	106 to 110	106 to 110

Last week's reports state the iron industry in France to be in a pretty satisfactory condition, a fair demand coming in for raw iron, as well as for the different articles of manufactured iron; prices are inclined to be firm.

On the Belgian iron market there has been a comparatively brisk business doing upon the week, pig iron being in good call and firm in quotation. The prices for malleable iron, on the other hand, must be considered as very unremunerative, and there is a decided inclination on the part of makers to raise their quotations; the majority, however, prudently prefer to wait till the position of the iron trade has become more settled. The plate and sheet trade continues lively.

A very firm tone prevails in the iron and steel trade of Rheinland Westphalia. The rising tendency, both in raw and in finished material, continues. Pig iron has been very briskly called for, and there was a decided increase in demand perceptible when compared to last week, inquiries on foreign account coming in more freely. Stocks show a decrease. The rolling mills are, for the greater part at least, healthily occupied, but the prices realised are justly considered as unsatisfactory. But, as the general tone of the market is steady and inclined to improve, an advance in quotations is very likely to take place in a week or two. Plates are in regular request, and for sheets quite an active demand is experienced. At a meeting held at Düsseldorf on the 14th inst., the Rhenish-Westphalian Plate Convention resolved to raise the price for boiler plates M. 5 p.t.; that for tank plates M. 2·50 p.t.

Output of coal in the Ruhr district was, for 1895, 34,684,880 t., against 34,305,340 t. the year before; in the Saar district production of coal amounted to 5,324,980 t., against 5,111,010 t., and in Silesia 12,937,850 t., against 12,185,120 t. Output in the three districts together was 52,947,710 t., against 51,601,470 t. in the year before, This shows, for the Ruhr district, an increase of 1·1 p.c.; for the Saar district 4·2 p.c.; for Silesia 6·1 p.c.; and for the three districts together an increase of 2·6 p.c. against 1894.

Official statements show value of import in France to have been, for 1895, 3,698,742,000 f., against 3,850,445,000 f. for 1894; and value of export is statistically stated to have been 3,387,851,000 f. against 3,078,145,000 f. for 1894.

TRADE AND BUSINESS ANNOUNCEMENTS.—Messrs. Wiggin, mica merchants, announce that they have taken temporary premises at 62 and 63, Minories, during the enlargement of their establishment at 102, Minories, by rebuilding on this site, and on the site of No. 103, which they have purchased for the purpose of necessary extensions.—The Southgate Engineering Company has removed its London office from 170, Fenchurch-street to Leadenhall House, Leadenhall-street. The office will be under the management of Mr. James Reid.—We understand that Mr. L. Pyke, late of Messrs. Pyke, Harris, and Co., Westminster, has sent in his resignation to that company, as managing director, owing to his having entered into partnership with Mr. Owen Lucas and Mr. Leopold Lucas, under the title of Messrs. Owen Lucas and Pyke, as consulting engineers.—As from the 1st of January inst. the firm of Messrs. Tabor, Trego, and Co., of New Broad-street and Bow, will consist of the former partners with the exception of Mr. G. S. Hunt, who then retires from the firm on the termination of the late partnership by effluxion of time.—We are informed that Mr. J. E. Weyman has resigned his position as managing director of the Trusty Engine Works of Messrs. Weyman, Hitchcock, & Co., Ltd.. Cheltenham, in which he is so largely interested. As is generally known, Mr. Weyman has worked very successfully in collaboration with Mr. Knight to develope the Trusty oil engine, and had previously brought out the Trusty gas engine, with which good results are obtained, before the business of Weyman and Hitchcock was converted into that of a limited company.

LAUNCHES AND TRIAL TRIPS.

On the 17th inst. the s.s. Chiswick, recently built by Messrs. Ropner and Son, of Stockton-on-Tees, to the order of the Britain Steamship Company, London, left the river Tees on her trial trip. This steamer has been built under the supervision of Mr. Spence, the inspector to the company, who was present during the trial trip.

Messrs. Fleming and Ferguson, shipbuilders and engineers, Paisley, launched from their yard last week the second of three steam hopper steamers which they are constructing to the order of the Admiralty for Portsmouth Dockyard. The dimensions of the vessel are 155ft. by 31ft. by 12ft. 5in., and she has a carrying capacity of 600 tons. The engines and machinery will be supplied by the builders.

On Friday, the 17th inst., the s.s. Sonnenburg, which has been built by Messrs. Wigham, Richardson, and Co., at their Neptune Works, Newcastle-on-Tyne, to the order of the Deutsche Dampfschifffahrts Gesellschaft "Hansa," of Bremen, and especially constructed for the River Plate trade, went for a very successful trial trip. The engines of this steamer are of the quadruple expansion type, on four cranks, balanced on the Yarrow, Schlick, and Tweedy system—a system which continues to give excellent results, both as regards the small consumption of fuel and the complete absence of vibration. The owners were represented by Mr. Wulff, the superintendent engineer of the company, under whose guidance the steamer has been completed. During the trial trip the machinery worked without the slightest hitch, giving satisfaction to all concerned; and the vessel sailed at once to take her place in the service between Germany and the River Plate.

On January 20th Messrs. Wm. Simons and Co., Renfrew, launched the first of two very powerful barge-loading dredgers constructed to the order of the British Admiralty. The vessel, which is named the St. Ives, is to be employed at Portsmouth Dockyard, and is of the following dimensions:—Length, 195ft.; breadth, 35½ft.; depth, 13ft. She is propelled by two sets of compound surface condensing engines of 1000 indicated horse-power—either set of engines being available for dredging—and has all the latest improvements in dredging appliances. The hoisting gear for bucket ladder, the bow and stern winches, and the side shoots for filling hopper barges are driven by independent engines. The length of the bucket ladder enables the buckets to dredge to a depth of 46ft. The rooms for officers and crew are placed on each side of the bucket well, and are comfortably fitted up. The dredger was launched with all her machinery on board, and in a few days will leave the Clyde for Portsmouth. Messrs. Huxham, Stewart, and Scoggins, Admiralty overseers, upon whose direction the dredger was constructed, represented the Admiralty at the launch.

On the 14th inst. Messrs. Irvine and Co., West Hartlepool, launched a fine steel screw steamer of about 4100 tons deadweight carrying capacity, built to the order of Messrs. The London and Northern Steamship Company—Pyman Brothers, managers—London. The vessel will take Lloyd's highest class, and has been built under special survey. Her dimensions are 314ft. by 44ft. by 23ft. 3in. The deck erections consist of poop, bridge, and topgallant forecastle. The saloon and cabins for captain and officers are fitted up in poop. The engineers are berthed under bridge deck at sides of engine-room, and the crew in topgallant forecastle. The hull is built on the web frame principle, with double bottom for water ballast fore and aft. Large hatchways are fitted, four steam winches by Irvine and Co., steam steering gear amidships, screw gear aft, two large donkey boilers, and direct steam windlass. The boats are placed on beams overhead, and all modern appliances will be fitted for general trading. Engines of the triple-expansion type are being supplied by Messrs. Blair and Co., Stockton-on-Tees. The hull and machinery have been built under the supervision of the owners' superintendents, Captain T. A. Pyman and Mr. Cromar. Miss Madeline Pyman named the vessel Pendower.

On the 15th inst. there was launched from the shipbuilding yard of Messrs. Wm. Doxford and Sons, at Pallion, the largest cargo boat ever built on the Wear, and with the exception of the Georgic and her sister ship, built by Messrs. Harland and Wolff at Belfast, the largest cargo-carrying boat afloat. The vessel, which, as she left the ways, was named the Algoa, has been built to the order of Messrs. Crow, Rudolph, and Co., of Liverpool, and has a deadweight carrying capacity of 11,300 tons. The builders' description furnished to the press states that the vessel is 475ft. long, 58ft. wide, and 34ft. 8in. deep. She has been plated on the Bell-Rockcliff system, whereby packing is dispensed with, and besides being on this account some 68 tons lighter than if plated on the old system, she presents a much handsomer apppearance. It is not only by the absence of packing that the weight of material used under this new system of plating is lessened, but also by the employment of shorter rivets in fastening outside strakes, and by using a smaller quantity of cement in the vessel's interior. As the reduction from these three different sources of saving admits of the safe loading of extra cargo to an equal amount, it will be seen that the Algoa possesses quite a unique advantage as compared with most other large cargo boats. For the purpose of facilitating the loading and discharging of her cargo, the vessel is fitted with eighteen derricks. Her construction has been under the superintendence of Mr. F. J. Pilcher, of Liverpool. At the completion of the launch the vessel was moored under the shearlegs for the purpose of being fitted with her engines and boilers, which have been constructed in the engineering department of the firm, their nominal horse-power being registered at 3000.

On Saturday morning last the s.s. Nanette had her trial trip. The Nanette has been built by Messrs. Wm. Gray and Co., for the Pyman Steamship Company, of West Hartlepool. She is a fine steel screw steamer, built to Lloyd's highest class, and her dimensions are:—Length over all, 305ft.; breadth, 42ft.; and depth, 21ft. 9in. The deck erections consist of a full poop, bridge over machinery space, and topgallant forecastle. A handsome saloon and cabins for officers, &c., are fitted up aft, the engineers' rooms are in the bridge, and the crew's accommodation forward, including a bath-room for seamen and firemen. The hull is built on the web-frame system, with a cellular double bottom; large hatchways, four steam winches, steam steering gear amidships, hand screw gear aft, two donkey boilers, patent direct steam windlass, boats on beams overhead, shifting boards throughout, stockless anchors, two masts with schooner rig, and a complete outfit for a first-class cargo vessel. The engines are of the triple-expansion type, and have been supplied by the Central Marine Engine Works of Wm. Gray and Co. They have cylinders 22in., 35in., and 59in. in diameter, with a 39in. piston stroke, and there are two large steel boilers working at a pressure of 160 lb. per square inch. After adjustment of the compasses, the engines were put full speed ahead for about an hour, when the speed attained was found to be 11 knots, everything running perfectly well and giving great satisfaction to those on board. There were present Captain T. A. Pyman and Mr. Fred. Smythe, representing the owners; Capt. Murrell, representing the builders of the vessel; and Mr. T. Mudd, representing the Central Marine Engine Works. The vessel is in charge of Capt. Clarke, and on the conclusion of the trial at once proceeded on her first run round to Garston, to load for the River Plate.

On Thursday afternoon, January 16th, Messrs. Joseph L. Thompson and Sons, North Sands Shipbuilding Yard, Sunderland, launched a finely modelled steel screw steamer, built to the order of Messrs. Rickmers, Reismuhlen, Rhederei, and Schiffbau, A.G., of Bremen. The vessel is 427ft. long, 50ft. 6in. wide, and 30ft. deep, moulded, and is designed to carry a deadweight of over 7200 tons with Lloyd's summer freeboard. She has been built to Lloyd's highest class, under special survey, on the three-deck rules, and has full poop, long bridge, and topgallant forecastle. The poop is arranged for cargo, and the officers, engineers, spare state-rooms, and saloon, in a house built on top of the bridge deck. On the top of this saloon house is placed the chart and wheel house. The crew are berthed in the topgallant forecastle. The vessel is built on the web frame principle, with intercostal stringers right fore and aft. The upper and main decks are of steel, the poop, bridge, and forecastle decks being of wood. Special attention has been paid to the loading and discharging arrangements, nine derricks being fitted, six of which are of steel. Seven powerful steam winches are placed on deck at the hatches, while the steam windlass is on the forecastle deck. The steam steering gear is placed at the after end of the engine-room, and is controlled by a wheel from the steering house on the bridge forward. A powerful screw gear is placed at the after end of the poop. Water ballast is carried in a cellular double bottom right fore and aft and in the after peak. The vessel is fore and aft schooner rigged, with pole masts. On the upper bridge deck amidships are placed four large boats, the two lifeboats being of seamless steel. The vessel has a graceful clipper stem, finished off with a well carved figure-head, and elaborate trail boards running away from this. The steamer is intended for Messrs. Rickmers' line between Europe and the East, and will further add to the reputation of the builders, being a notable addition to the many modern up-to-date cargo carriers which they have recently turned out. The engines are by Messrs. George Clark, Limited, and are of the following sizes:—27in., 43in., and 72in., with a stroke of 48in. Steam is supplied by four large multitubular boilers working at 180 lb. pressure, and all the most modern improvements in propelling machinery are fitted. The launch, which was witnessed by a large number of people, was most successful, the vessel, on leaving the ways, being named the Maria Rickmers by Mrs. Adolph Heine, wife of Messrs. Rickmers' superintending engineer.

NEW RAILWAY FOR NEW YORK.—The proposed tunnel railway scheme of the New York and Long Island Railway Company was revived at the last stockholders' meeting, by voting to increase the stock from 100,000 to 20,000,000 dols. for this purpose, provided that the consent of the Railway Commissioners of New York and New Jersey can be obtained. This company proposes to build twenty-six miles of double-track railway, beginning in New Jersey, and to tunnel under the Hudson River, under 42nd-street, and under the East River to Long Island. The directors elected include Mr. A. J. Benedict, of London.

THAMES FLOODS.—The Thames Conservancy Board has transmitted to the Rivers Committee of the London County Council the report of a committee appointed by the Board to consider the question of the floods in the Thames Valley. The report, which has been unanimously adopted by the Board, expresses the opinion that the only effective method of reducing the floodings is by widening and deepening the channel of the river, but that great care would have to be shown in dealing with the matter, as it might affect agricultural lands. The question is one which the local authorities and landowners in the Thames Valley should consider, and in the event of their not having powers they should apply to Parliament for the right to raise money to enable works to be carried out to prevent floodings. The committee hopes that in future the Conservancy Board will have sufficient funds to enable the Board to execute dredging operations for navigation purposes, which will, at the same time, lower the level of the flood waters. Accompanying the report of the committee is a report by the Conservancy engineer, who states that, in his judgment, the weirs, as at present constructed, are not responsible for the inundations; but he agrees with the suggestion that at many of the bridges there is insufficient waterway, especially where the flood arches have been blocked or silted up, and that the old channels and backwaters should be cleared. The expense of enlarging the channel to effect an alteration of the level of extraordinary floods would be enormous. It would cost £85,000 for the works necessary to relieve the lands between Staines and Teddington.—*St. James's Gazette.*

606. Page Turner, W. S. Shepherd, London.
607. Revolving Nozzles for Liquids, E. E. Dulier, London.
608. Taps, J. Stewart, London.
609. Signalling Apparatus, J. Law and C. Ash, London.
610. New Brake for Velocipedes, F. Sparkes, London.
611. Attachment for Velocipedes, W. U. Paull, London.
612. Hurricane Lanterns, J. Hinks and Son, and H. D. Hinks, London.
613. Fare-registering Apparatus, F. W. G. Bruhn, London.
614. Manufacture of Castor Bowls, J. Harrington, London.
615. Tools for Slide Rests of Lathes, W. Hillman, London.
616. Rails, P. R. J. Willis.—(*H. Stearns and E. Doughty, United States.*)
617. Covering Ships' Bottoms, F. H. Snyder, London.
618. Extraction of Metals from Ores, J. B. Torres, London.
619. Ladies' Safety Bicycle Rest, F. Hooper, London.
620. Automatic Flushing Cisterns, J. J. Marsland, London.
621. Distending Sleeves, J. Alcock.—(*J. J. Konigs, Australia.*)
622. Tunnelling Apparatus, H. H. Dalrymple-Hay, London.
623. Devices for Typewriting Instruments, C. L. Baker, London.
624. Gas Engines, A. G. New, London.
625. Wheels, T. H. Deakin, F. S. Geath, and D. Powell, London.
626. Burglar Alarm, H. E. Lindo, London.
627. Music Cabinets, M. Liebich, Canada.
628. Fireplaces with Ventilating Shaft, A. H. Tiltman, London.
629. Curtain Poles, M. Lansing, London.
630. Screw Buttons, D. L. Richard and J. A. Bird, London.
631. Cylinders of Musical Boxes, P. Calame-Jaccard, London.
632. Chain Driving Gear, E. Barron, London.
633. Manufacture of Neck-ware, W. Willeringhaus, London.
634. Pictures, S. Hildesheimer and Co.—(*L. Sonn, Germany.*)
635. Gas Meters, S. J. Whitbread and J. R. Griffiths, London.
636. Bleaching of Flour, W. A. McArthur and J. Atherton, London.
637. Billiard and other Cues and Tips, H. Misener, London.
638. Waist Bands for Supporting Skirts, A. Breese, London.
639. Toys, J. W. H. Vivian, London.
640. Boxes, H. W. Chapman, London.
641. Application of Fuel to Furnaces, R. S. Richards, London.
642. Apparatus for Roasting Coffee, W. Parnall, London.
643. Stone Steps, A. W. Perriman and W. Owen, London.
644. Drinking Vessels and Saucers, W. A. C. Waller, London.
645. Means for Delivering Tickets, A. Marsh, London.
646. Construction of Bicycles and Tricycles, L. Frazer, London.
647. Device Applicable to Carboys, H. J. Gardiner, London.
648. Pneumatic Tires, J. S. Taylor and C. Davies, Liverpool.
649. Fuel, J. S. Taylor and C. Davies, Liverpool.
650. Waterproof Fabrics, I. Frankenburg, Manchester.
651. Waterproof Fabrics, I. Frankenburg, Manchester.
652. Wire Netting, Wire-work, &c., R. H. Silcock, Liverpool.
653. Rotary Machines for Printing, I. Lam, Liverpool.
654. Gutta-percha, E. Sérullas and F. Hourant, London.
655. Housings for Cycles, R. L. Hickes, London.

10th January, 1896.

656. Toy Windmill, T. Barter, Ross.
657. Drill, G. W. Davis, West Bromwich.
658. Seats, L. Dawes, London.
659. Safety Syphon Valve Taps, H. Sutcliffe, Halifax.
660. Chimney Cowl, G. Williams and W. Jackson, Tewkesbury.
661. Cricket Bats, F. Bryan, London.
662. Spittoon, J. G. Patterson, H. Tate, and J. S. Purvis, Gateshead.
663. Cotton Reel, E. W. Wynne, Liverpool.
664. Apparatus for Driving Tacks, W. H. Dorman, Stafford.
665. Metal Tubular Roller, E. Entwistle, sen., Ashton-under-Lyne.
666. Gravity Wheel, T. Haysman, Portsmouth.
667. Bobbins for Treating Fibrous Substances, T. Dixon, Keighley.
668. Looms for Weaving, A. Johnstone and J. W. Parker, Bradford.
669. Wigs, G. Hattersley, Keighley,
670. Stucco Glass, F. R. Cross, Birmingham.
671. Colanders, E. W. Holland, Birmingham.
672. Collar Stud and Tie Adjustment, E. A. Smeeton, London.
673. Separating the Cream from Milk, H. Lavens, Brussels.
674. Feeding Oil and Spirit Lamps, &c., H. Christy, Glasgow.
675. Non-slipping Guard for Tires, R. J. Glanvile, Burnham
676. Envelopes, F. Owen, Cardiff.
677. Fastening for Hampers, J. Rowlatt, Tunbridge Wells.
678. Indication of Boiling in Kettles, A. Smith, London.
679. Crank and Pedal Combination, A. Bills, London.
680. Velocipede Brakes, A. Lavelly and B. Hobi, London.
681. Photographic Apparatus, &c., J. D. Lysaght, London.
682. Artificial Fuel, H. C. B. Forester, London.
683. Corks, K. Fraser, jun., London.
684. Handle for Preserve Jars, R. J. Smith, Bromsgrove.
685. Power Gear for Bicycles, &c., W. T. Lord, London.
686. Pianos, J. E. Jansson, London.
687. Pie Dish, J. Pooley, London.
688. Rack for Cards and Photographs, H. C. Hall, London.
689. Reversible Ladies' Side Saddle, J. Kidman, London.
690. Extinguishing Candles, G. H. Laxton, London.
691. Construction of Baking Surfaces, P. Pfleiderer, London.
692. Clocks, E. P. West and C. A. Remane, London.
693. Life-belts, J. N. Layton, London.
694. Cover for Inspection Eyes of Drains, W. J. Bugler, London.
695. Billiard Cue Tip, C. Jessett and H. N. Phillips, London.
696. Umbrella Stands, E. T. Hughes.—(*T. C. Perry, United States.*)
697. Letter-boxes, Pillar-boxes, &c., T. J. Jenkins, London.
698. Colouring-matters, O. Imray.—(*The Society of Chemical Industry in Basle, Switzerland.*)
699. Electric Arc Lamps, H. N. Moody, London.
700. Stereoscopes, J. Carpentier and L. Gaumont, London.
701. Electric Signalling Apparatus, B. Marinovitch, London.
702. Packing Goods, S. Learoyd and W. Scott, London.
703. Utensils for Boiling Purposes, O. B. Bates, London.
704. Feed-water Cleaners, C. A. Houfe.—(*W. W. Houfe, China.*)
705. Printed Axminster Carpets, J. Nicholls, London.
706. Bottles, J. M. Richards.—(*H. K. Terry, United States.*)
707. Locomotive Grass Mower, &c., G. E. Arnold, London.
708. Manufacture of Scotch Fabrics, J. Joubert, London.
709. Velocipede Steering Heads, R. Haddan.—(*F. Chaligné, France.*)
710. Electric Accumulators, A. C. Miles and B. F. de Morgenstern, London.
711. Arc Lamps, A. C. Miles and B. F. de Morgenstern, London.
712. Electric Motors, A. C. Miles and B. F. de Morgenstern, London.
713. Velocipedes, B. C. Hicks, London.
714. Velocipedes, B. C. Hicks, London.
715. Fountains, H. H. Lake.—(*The firm of E. B. Söhne, Austria-Hungary.*)
716. Apparatus for Desiccating Fruit, J. Lewthwaite, London.
717. Hauling Boats on Rivers, &c., N. Gherassimoff, London.
718. Roundabouts, E. Tuteur, London.
719. Electrical Accumulators, B. Willcox.—(*La Société L'Accumulateur Fulmen, France.*)
720. Obtaining Hydro-sulphide of Sodium, &c., B. Willcox.—(*The firm of Chemische Fabrik Griesheim, Germany.*)
721. Driving Gear for Bicycles, &c., A. T. Collier, London.
722. Electric Arc Lamps, J. I. and J. E. Thornycroft, London.
723. Snaffle and Curb Reins, O. E. Hollingworth, Westminster.
724. Fastening Carpets to the Floor, O. E. Hollingworth, Westminster.
725. Furniture Castors, O. E. Hollingworth, Westminster.
726. Files for Holding Letters and Bills, W. Beller, London.
727. Files for Holding Letters and Bills, W. Beller, London.
728. Automatic Lever Pulleys, S. Wilcock, London.

11th January, 1896.

729. Shuttle Picker Check Swell for Looms, W. and R. F. Haigh, Skipton.
730. New Game, C. M. Linley, London.
731. Self-propelled Vehicles, J. H. Hamilton and A. Rollason, Sandiacre.
732. Calendars, C. Tyler, London.
733. Open Air Seats, T. H. Taylor, Belfast.
734. Renewing Sash Lines, J. R. Knight, Black Rock, Co. Dublin.
735. Lathes, H. Liebert, Manchester.
736. Electric Tramways or Railways, W. B. Edgar, Glasgow.
737. Doubling Frames, B. A. Dobson and W. Hamer, Manchester.
738. Corner and Frame for Beds, G. Rogers, Birmingham.
739. Signalling Apparatus, W. F. Balls and W. Lowes, South Shields.
740. Pillar, Wall, and other Letter Boxes, O. D. Kinnersley, Bristol.
741. Excluding Dust from Lamps, G. M. Archibald, Stockton-on-Tees.
742. Preventing Smoky Chimneys, S. J. Cairns, Southport.
743. Measuring and Draught Tap, G. M. Dudley, Dublin.
744. Cycle Driving Gear, J. McKenny and F. L. North, Dublin.
745. Cycle Stand, H. Budden, London.
746. Wood Screws and the like, C. Horton, Birmingham.
747. Table Knife, G. F. Vardy, London.
748. Regulating Spinning Machinery, C. Bergmann, London.
749. Collars for Rock Drills, W. H. Taylor.—(*J. Daniell, India.*)
750. Cycle Carrier and like Bags, A. M. Lermit, Birmingham.
751. Rubber Tipped Ferrule, S. R. Gladston, North Shields.
752. Calico Printers' Blanketing, J. Wood, Manchester.
753. Stopper for Bottles, J. Marcroft and T. Rawston, Rochdale.
754. Bottle Stoppers, J. Marcroft and T. Rawston, Rochdale.
755. Drop-down Guns and Rifles, J. W. Smallman, Nuneaton.
756. Fresh Air Inlet for Drains, G. W. Knowles, Somerset.
757. Outdoor Seats, A. W. Molloy, Tonbridge.
758. Grinding Spindles, W. Bodden and F. Ashton, Manchester.
759. Revivifying Spent Limes, &c., G. R. Hislop, Glasgow.
760. Street Gas Lamps, C. R. Bellamy, Liverpool.
761. Gas Fittings for Street Lamps, C. R. Bellamy, Liverpool.
762. Drain Stoppage Indicator, T. G. Goodwin, London.
763. Construction of Curling Tongs, G. Skinner, London.
764. Ship Construction, P. F. Maccallum, Helensburgh.
765. Coal Tipplers and like Machinery, J. Martin, London.
766. Treating Spent Hops, E. Davies and H. M. H. Goodfellow, London.
767. Internal Combustion Motors, F. O. Prince and The Setay Motor Engine Syndicate, Ld., London.
768. Door Handles, A. G. Green, London.
769. Form Turning Machines, C. A. Allison.—(*The Garvin Machine Company, United States.*)
770. Paper Articles, W. B. Benns.—(*G. Piprot, France.*)
771. Process for Combusting Coal Dust, M. Seipp, London.

772. Cycle Stands, F. S. Buckingham, London.
773. Machines for Necking Cylindrical Cases, &c., W. B. Challen and Taylor and Challen, Limited, London.
774. Lathes for Trimming Cylindrical Cases, &c., W. B. Challen and Taylor and Challen, Limited, London.
775. Making Barrel Root Cutters, E. E. Bentall, London.
776. Folding or Collapsible Boxes, W. Riley, London.
777. Oil Lamp Stands, H. Priest and J. W. B. Wright, London.
778. Secondary Batteries, H. W. Headland, London.
779. Sieves, H. Demant, London.
780. Secondary Electric Batteries, H. Leitner, London.
781. Non-fillable Bottles, W. C. Sherman, London.
782. Envelopes, A. Mortensen, London.
783. Cigarette Papers, I. Goldfar and L. R. Rowland, Glasgow.
784. Internal Combustion Motor Engines, P. Burt, Glasgow.
785. Valve Controlling Device, J. F. Batchelor, Brooklyn, U.S.A.
786. Gas and Oil Engines, M. H. Smith, London.
787. Cycles, L. Stein, London.
788. Combined Fabric and Threads in Hemming and Similar Work, J. Deeks.—(*H. H. Fefel, United States.*)
789. Photographic Cameras, L., L. E., and H. Holmes, London.
790. Refrigerators or Cooling Chambers, R. J. A. Hankow, London.
791. Voltaic Batteries, W. Walker, jun., F. R. Wilkins, J. Lones, and C. Vernon, London.
792. Refrigerating Chambers, &c., E. Willows, London.
793. Electrical Lamp, H. J. Dowsing and H. S. Keating, London.
794. Electrical Lamp, H. J. Dowsing and H. S. Keating, London.
795. Cooling the Inlet Valves of Gas and Oil Motor Engines, C. D. Abel.—(*The Gasmotoren Fabrik Deutz, Germany.*)
796. Propelling Vehicles, C. F. de Kierzkowski-Steuart, London.
797. Gas Brackets, H. Crawley and G. A. Metcalfe, Liverpool.
798. Enamel Tins, C. Davies and J. S. Taylor, Liverpool.
799. Separating Oil from Water, H. Hinterberger, London.
800. Motor Carriage, C. Keller, London.
801. Rendering the Joints of Cylinders Fluid-tight, J. P. Gauthier, N. Henriot, and A. Jourdanet, London.
802. Splitting or Cutting Cigar Ends, D. H. Fisher, London.
803. Fluid Pressure Regulating Valves, W. Ross, Glasgow.
804. Safety Valves for Domestic Boilers, J. Gourlay, Glasgow.
805. Window Flower Boxes, J. F. Struthers, Glasgow.
806. Wheels for Cycles, J. Sternberg and A. Maneau, London.
807. Appliance for Retaining Cigars, F. X. Hardt, London.
808. Tobacco Boxes, H. Hebden, Harrogate.
809. New Tobacco Pipe, M. Frilley, Brussels.
810. Supply of Electricity, Gas, &c., G. C. Fricker, London.
811. Refrigerating Machinery, F. W. Walker, London.
812. Chain Wheels of Cycles, &c., J. Blackmore, London.
813. Steering Arrangements of Cycles, L. Frazer, London.
814. Driving Gear of Cycles, S. H. Crocker, London.
815. Luggage Carrier for Cycles, J. W. Innes, London.
816. Producing Methyleneditannic Acids, E. Durkopf, London.
817. Sifting Machines, H. H. Lake —(*J. E. Mitchell and Harmon Manufacturing Company, United States.*)
818. Files for Holding Letters, Bills, &c., W. Beller, London.

13th January, 1896.

819. Incandescent Body for Lamps, W. P. Thompson. —(*The Continental-Gas-Glühlicht-Aktien gesellschaft "Meteor" vormals Kroll, Berger, and Co., Germany.*)
820. Sewing Machines, W. A. Robertson, Belfast.
821. Purification, &c., of Water, J. H. Williams, Waterford.
822. Syphon Cistern, S. Thompson, J. McEwen, and T. Keates, Birmingham.
823. Joints for Cornice Poles, J. Whitfield, Birmingham.
824. Tobacco Pipes, J. Bird and G. B. Shuttleworth, Birmingham.
825. The Luggage Traveller, W. Crabtree, Heywood, Lancs.
826. Protection of Cycle Chains, C. Eltringham, Sunderland.
827. Round Frames for Dressing Ores, W. Trevorrow, Redruth
828. Movable Bar of Coal Vehicles, I. Lewis and J. E. Price, Merthyr Tydvil.
829. Fastener for Driving Tapes of Spinning Frames, W. Dargue, Halifax.
830. Pneumatic Guns, D. M. Mefford, London.
831. Packing Cases, &c., F. W. Farr, London.
832. School Desks, F. H. Fisher, Birmingham.
833. Apparatus for Bending Strawboard, &c., J. E. Thornton, Altrincham.
834. Grinding the Ends of Spindles, W. Bodden and F. Ashton, Manchester.
835. Time-comparing Device, W. P. Thompson.—(*A. Koechlin, Germany.*)
836. Disinfecting Plants, &c., J. T. Wägener, Manchester.
837. Hydrocarbon Motors, E. Wiseman and J. Holroyd, Manchester.
838. Tires for Cycles, W. Guthrie, Glasgow.
839. Needles for Sewing Machinery, J. W. Blakey, Leeds.
840. Railway Carriages, J. H. Annandale, Glasgow.
841. Furnace for Producing Coke, G. W. Breffit and F. G. Treharne, London.
842. Manufacture of Electric Conductors, S. O. Cowper-Coles, London.
843. Waterproof Unbreakable Bootlace, J. C. Browne, Tewkesbury.
844. Automatic Carving-fork Guard, E. Putley, London.
845. Electrical Appliances, D. Weisz and E. Epstein, London.
846. Manufacture of Cigarettes, S. and A. Grunebaum, London.
847. Automatic Apparatus, J. I. and J. E. Thornycroft, London.
848. Steam Traps, J. I. and J. E. Thornycroft, London.
849. Reloading Apparatus, J. E. Grout, London.
850. Apparatus for Overarches, &c., E. H. Bradley, London.
851. Duplicate Bag Frame, J. F. Meek, London.
852. Grain Storage Bins, J. Donaldson, Liverpool.
853. Cigar and Cigarette Holders, J. H. Scott, London.
854. Rolling Mill, H. Ehrhardt, London.
855. Apparatus for Drying Tea, &c., W. W. Wardle, London.
856. Measuring Arrangement for Bottles, P. G. Challis, London.
857. Letters, &c., for Advertising, W. G. Pether, London.
858. Apparatus for Carburetting Air, A. Devis, London.
859. Toe-clip, J. W. Colling, London.
860. Construction of Glazed Roofing, H. Becker, London.
861. Life-saving Jackets, E. Channing, London.
862. Sight-feed Lubricators, F. Bamford and W. Wadsworth, London.
863. Pneumatic Tires, W. J. Goddard and A. H. Trigwell, London.
864. Supplying Water to Roots of Plants, F. C. Dame, London.
865. One-trigger Double-barrel Guns, T. Southgate, London.
866. Hydraulic Engines, P. Frenzeny and D. H. Fisher, London.
867. Centrifugal Roller Mills, H. Propfe and G. Zarniko, Liverpool.
868. Electric Meters, C. Raab, London.
869. Photographing Panoramic Views, L. Jeffery, London.
870. Pumps, J. C. Merryweather and G. Harris, London.
871. Preventing Halation in Dry Plates, W. Haydon, London.
872. Apparatus for Raising Sewage, S. H. Adams, York.
873. Obtaining Carbonic Acid from Gases, W. Raydt, London.
874. Hydraulic Machine Jiggers, C. Simon, London.
875. Tiles, W. A. C. Waller, London.
876. Cycle, C. J. Gregg, London.
877. Manufacture of Impermeable Fabrics, J. J. Mann, London.
878. Cricket Bat, W. L. N. Clayton, London.
879. Measuring Instruments, Evershed and Vignoles and S. Evershed, London.
880. Electric Heaters, G. Ewart and J. Vaughan-Sherrin, London.
881. Cutting Clay into Bricks or Blocks, T. Buck, London.
882. Preventing Gas Freezing in Mains, The Whessoe Foundry Co. —(*The Berlin - Anhaltische Maschinenbau-Aktiengesellschaft, Germany.*)
883. Clothes Peg, L. Doring, London.
884. Regulating Temperature of Motor Vaporisers, E. Capitaine, London.
885. Transmission of Force, E. Capitaine, London.
886. Road Vehicles, R. W. Hannah, London.
887. Varying the Driving Speed in Cycles, G. Delannoy, London.
888. Secondary Batterry, A. U. Alcock, London.
889. Apparatus for Refrigerating Liquids, F. Godard, London.
890. Diazo Compounds, G. W. Johnson.—(*Kalle and Co., Germany.*)
891. Boiler Furnaces, J. Brown and Co. and J. Nodder, London.
892. Boiler Furnaces, J. Brown and Co. and J. Nodder, London.
893. A Bicycle Alarm Brake, W. Woodham, London.
894. Bed Table, A. Wilks, London.

14th January, 1896.

895. Temples of Looms for Weaving, F. J. Dutcher, London.
896. Simplex Recording Indicator, A. Cotgreave, London.
897. Head Clips used by Furriers, W. G. Speck, London.
898. Lubrication of Spindles, E. and S. Tweedale, and J. Smalley, Castleton.
899. Cans for Delivery of Milk, H. W. Townsend, Newport.
900. Liquid Sealed Valves for Gases, J. W. Wailes, Liverpool.
901. Milling Machines, T. Lumb, T. Walshaw, and D. White, Bradford.
902. Fire Ranges, S. H. Jefferys, Halifax.
903. Tooth Brush, J. Brennan, Manchester.
904. Plug Cocks, W. Moorhouse, Manchester.
905. Appliances for Holding Cards, L. Myers, Birmingham.
906. Fixing or Securing Scarves, W. Garratt, Birmingham.
907. Metallic Cots, R. P. Taunton, Birmingham.
908. Textile Fabrics, J. H. MacMillan and J. Mason, Manchester.
909. Flexible Shafting, M. G. Gillette, London.
910. Rotary Brushes, M. G. Gillette, London.
911. Singeing Fabrics, F. Bosshardt.—(*G. Balfe, France.*)
912. Perfect Ring Stretcher and Closer, J. Hollis, Ilkeston.
913. Washing Photographic Prints, W. Kerr, Glasgow.
914. Surgical Splint, G. W. White, Bristol.
915. Electric Transformers, E. Scott, Wolverhampton.
916. Non-sparking Switch, E. Scott and E. J. Cochrane, Wolverhampton.
917. Sailor Dance for Stage Work, B. Seward, Bradford.
918. Apparatus for Barrels, W. Hazlehurst, Rochdale.
919. Stoppering Bottles, J. Fitton and E. Looker, Rochdale.
920. Mode of Testing Sewer Pipes, C. L. J. White, Dublin.
921. Mourning Label for Letter Paper, J. Laidlaw, Glasgow.
922. Machine for Crushing Ores, T. Lees and D. N Shaw, Glasgow.
923. Stoppering or Closing Bottles, W. Pasquill, Keighley.
924. Heating Clothes-drying Closets, H. C. Longsdon, Keighley.
925. Effervescent Beverages, J. Hargreaves, Farnworth-in-Widnes.
926. Door Curtains, R. Darling, Glasgow.
927. Hydrocalor, S. Reilly, Plymouth.
928. Discharging Salts from Evaporators, J. Foster, Glasgow.
929. Piston Rings, J. Menzies, Glasgow.
930. Boot and Shoe Ventilator, T. Grainger, Rhondda Valley.
931. Electrical Device for Igniting Gas, J. K. Semple, Glasgow.
932. Wheel Naves, P. Fyfe, Glasgow.
933. Air Valves, P. Fyfe and W. Dewar, Glasgow.
934. Tobacco Pipes, G. Gilman, London.
935. Machinery for Moulding Bricks, A. Pullan, London.
936. Bells for Cycles, H. Lucas and B. Steeley, London.
937. Hydraulic Rams, G. F. Hurst, London.
938. Utilising Energy of Fluid in Motion, G. A. Benoit, London.
939. Blanks for Horseshoe Nails, D. E. Kempster, London.
940. Taps for Emptying Closed Vessels, C. A. James, London.
941. Pads, D. Appleton, London.
942. Blow Lamps, T. Warwick, London.
943. Tongs, G. Skinner, London.
944. Game, R.Hurrell, Essex.
945. See-saw, E. J. Nowell, London.
946. Typewriting Machines, J. D. Daugherty, London.
947. Turning Malt on a Kiln Floor, C. E. Mumford, London.
948. Stowing of Chain Cables, J. Kennedy.—(*R. P. Baines, Belgium.*)
949. Reducing Cellulose Bodies, W. Theodorovic, London.
950. Tin Openers, G. Parrott, London.
951. Railway Signal Apparatus, A. G. Walker and P. Black, London.
952. Tobacco Pipes, E. W. Thurgar, London.
953. Aerial Transport of Performers, C. R. Cox, London.
954. Laundry Irons, J. Manning and J. R. S. Hayes, London.
955. Implement for Trimming the Nails, J. Cunningham, London.
956. Hock Boot, F. Elliott, London.
957. Lamps for Lighting, E. Thorpe and W. Brandon, London.
958. Warming Stoves, E. Thorpe and W. Brandon, London.
959. Magazine Repeating Fire-arms, P. Mauser, London.
960. Horse Collar, A. Lawton, London.
961. Instruments for Stopping Teeth, A. Meisinger, London.
962. Lap Machines, O. Schroeter, London.
963. Ships Driven by Motive Power, F. W. Jones, London.
964. Telephonic Apparatus, C. J. Schwarze, London.
965. Braiding Machines, H. H. Lake.—(*W. C. Fisher, United States.*)
966. Parlour Game, W. D. R. H. Kerr, London.
967. Nailless Horseshoes, G. L. Reynolds, London.
968. Administering Anæsthetics, J. K. Gailey and C. A. Dunbar, London.
969. Blowing Engines, &c., W. P. Thompson.—(*E. Reynolds, United States.*)
970. Plansichters, &c., W. P. Thompson.—(*G. Luther, Germany.*)
971. Automatic Weighing and Packing of Goods, S. Learoyd and W. Scott, London.
972. Artificial Light Apparatus, J. Parkinson, Liverpool.
973. Harness Fittings, T. A. Quilliam, Liverpool.
974. Indicating Rise or Movement of Valves, E. W. Beech, London.
975. Incandescent Gas Burners, R. Holbrook, London.
976. Electric Arc Lamps, H. J. Fisher, London.
977. Sychronising of Alternating Current Motors, H. F. Parshall, London.
978. Self-closing Door Hinges, E. Edwards.—(*C. Mine, Germany.*)
979. Folding Furniture, J. W. Morison, London.
980. Electrically Regulating Temperature, A. W. Isenthal, London.
981. Printing Telegraphic Messages in Type, G. M. Gibson, London.
982. Temporary Binders, A. L. Weis, London.
983. Bailway Frogs, D. MacPherson, London.
984. Stalls for Cattle, G. C. Marks. - (*S. M. Parker, United States.*)
985. Locking Apparatus for Windows, W. Nicholson, London.
986. Electro-deposition of Metals, J. C. Graham, London.
987. Sugar-boiling Furnaces, R. Buxton and A. Ball, London.
988. Sheaths for Pencil Erasers, A. de V. Hunt, London.
989. Projectiles, J. Luciani, London.
990. Gradient Finders, A. Moore, jun., London.
991. Blast Process for Engraving, H. H. Leigh.—(*T. Truchelut, France.*)
992. Calculagraphs, H. Abbott and E. A. Currier, London.
993. Street-sweeping Machines, P. Jensen.—(*The International Sweeping Machine Company, United States.*)
994. Street-sweeping Machines, P. Jensen.—(*The International Sweeping Machine Company, United States.*)

1060. Radiators for Petroleum Lamps, A. F. A. Roxendorff, London.
1061. Let-off Mechanism for Looms, J. Poyser, London.
1062. Heel Building, &c., Machines, O. Robinson, London.
1063. Pipes and Wire, A. I. Summers, London.
1064. Tubes, R. Bungeroth, London.
1065. Fittings for Syphons, R. G. G. and W. S. G. Ellis and R. O. Jones, London.
1066. Conveying Vehicles, E. R. Calthrop and J. C. Taite, London.
1067. Pneumatic Tires, C. Woolley and T. Dunn, London.
1068. Recovering Metals from Solutions, J. C. Graham, London.
1069. Electrical Condensers, C. Pollak, London.
1070. Teapots, J. Teasdale, London.
1071. Tobacco Pipe, F. G. Sayer, London.
1072. Ventilating Apparatus, D. Rees, London.

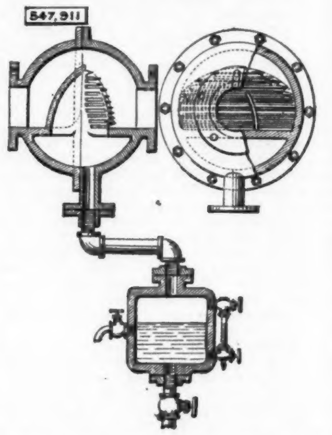
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

547,911. Steam Separator, *W. Christie, New York, N.Y.—Filed March 8th*, 1895.

Claim.—A steam separator, comprising a casing, a partition within the casing for dividing it into a steam chamber and a discharge chamber, the said partition being provided with an upwardly extending portion toward the outlet side of the casing and a baffle-plate extending upwardly on the inlet side of the casing, the said upwardly extending portion and baffle-plate being extended to within a short distance of the top of the casing, whereby the steam is caused to turn bodily upward and over the top of the baffle-plate for throwing the contained foreign substances through the baffle-plate into the discharge chamber, substantially as set forth.

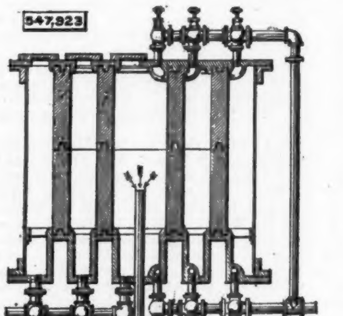
547,911



547,923. Filter, *C. W. Isbell, New York, N.Y.—Filed September 11th*, 1894.

Claim.—The combination of a cylinder of filtering material, a surrounding casing provided below the said cylinder with an annular pocket for the collection of impurities and having an inlet following the direction of the circumference of the cylinder, and one or more baffle-plates arranged across said pocket, substantially as and for the purposes herein set forth.

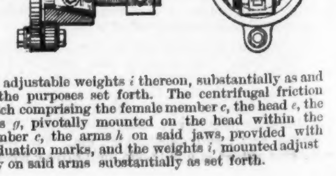
547,923



547,930. Coupling for Electro-motors, *F. Marburg jun., Buffalo, N.Y.—Filed May 14th*, 1895.

Claim.—The combination with an electro-motor and a main shaft to be driven thereby, of a coupling clutch C, one member of which is carried by said main shaft and the other member by the armature shaft of the motor, the male member of the clutch comprising the two jaws *g*, having graduated arms *h*, and adjustable weights *i* thereon, substantially as and for the purposes set forth. The centrifugal friction clutch comprising the female member *c*, the head *e*, the jaws *g*, pivotally mounted on the head within the member *c*, the arms *h* on said jaws, provided with graduation marks, and the weights *i*, mounted adjustably on said arms substantially as set forth.

547,930



AFTER THE GREAT RAILWAY RACE.

By CHARLES ROUS-MARTEN.

SEVERAL interesting questions suggest themselves with reference to the recent competitive accelerations of the East and West Coast expresses to Scotland, which the respective authorities forbid us to regard as a "race," it being merely an effort to see who could get to Aberdeen first! Now that the race has definitely resulted, for the present, in the West Coast accepting second place by the large beating of 50 minutes—the West Coast time to Aberdeen being 11 h. 15 min., as against 10 h. 25 min. of the East Coast—the occasion is a convenient one for noting more particularly what was actually achieved, than was possible during the struggle, and for considering what are the lessons that the experiences of July and August have taught.

In the first place, it may reasonably be asked: What were the actual record times? Which were the correct figures, of the half dozen or more different versions which have been published in various quarters?

The West Coast official times of the "record" run of August 22nd—23rd, as registered by the London and North-Western Railway, are as follow:—

Miles (Bradshaw)	Stations		Officially recorded times.	Officially recorded average speeds.	Remarks.
			h. m. s.	miles p. hr	
—	Euston	dep.	8 0 0	—	Engine Adriatic, No. 1309, load three eight-wheeled vehicles.
17½	Watford.. ..	pass	8 17 0	61·0	
31¾	Tring	,,	8 30 0	63·1

408¾	Larbert	,,	2 27 0	61·5	
417	Stirling	,,	2 34 30	64·0	
450	Perth	arr.	3 7 30	60·0	Engine No. 17, same load.
		dep.	3 9 30		
482¼	Forfar	pass	3 39 0	66·1	
501½	Kinnaber ..	,,	3 57 0	64·2	
516¾	Drumlithie ..	,,	4 9 30	74·4	There is manifestly an error in this timing and speed estimate.
523¾	Stonehaven ..	,,	4 16 30	57·8	
539¼	Aberdeen ticket platform ..	arr.	4 30 0	61·9	
		dep.	4 31 0		
539¾	Aberdeen Sta.	arr.	4 32 0		

There are several discrepancies in these times. The Caledonian official notes made the train arrive at Carlisle a minute later than according to the London and North-Western time, and leave half a minute later. A third independent timing places the Carlisle arrival time between the two, viz., at 12.36; also the Crewe arrival at 10.28. Further, there is clearly an error in the time of passing Drumlithie. It is utterly improbable that the train maintained a speed of 74·4 m.h. up the somewhat steep ascending gradients from Kinnaber to Drumlithie, and then descended the incline to Stonehaven at only 57·8 m.h., a slower rate than that at which the Shap bank was ascended. The Caledonian timing of passing Stirling differs by five minutes from that of the London and North-Western. The latter is almost certainly the more correct, as it is absurd to suppose that after deliberately descending the long down grade to Stirling at 55 m.h., the train rushed violently up the steep bank to Kinbuck at 70 miles an hour. On the whole, it will be safer to regard the intermediate times as merely approximate—though very likely close approximations in most cases to accuracy—and not to base any theories or conclusions upon the exact figures. But, accepting the terminal figures as reasonably accurate, the following remarkable average speeds, from start to stop, result:—

	m.h.
Euston—Crewe	64·3
Crewe—Carlisle	67·2
Carlisle—Perth	60·5
Perth—Aberdeen ticket platform	66·7

It is noteworthy that whereas both the London and North-Western runs were "records," and while the final run of the Caledonian was apparently a "tie" with that of the same engine two days previously, the Carlisle-Perth run fell considerably short of what might have been expected, even allowing for the climb up the Beattock bank. Engine No. 90, with three vehicles, on this occasion took 149½ minutes to run the 150¾ miles from Carlisle to Perth without a stop, whereas on the previous day No. 78, of the same class, made the run with an additional vehicle, and including three minutes stoppage at Stirling, in half a minute less time, or in 3½ minutes less running time, without any allowance for loss in slackening to stop and starting again from Stirling. No. 78, with the heavier load, passed Beattock two minutes quicker, and stopped at Stirling in 3½ minutes quicker time than No. 90 on the "record" day took to *pass* the station; while No. 78, with the additional coach, ran from Stirling to Perth—start to stop—in the same time that No. 90 took from passing Stirling at speed to the stop at Perth. Clearly, then, this length could have been quickened by at least six minutes, and probably more, perhaps by ten minutes.

Again, it is curious that the comparatively easy length from Euston to Crewe should have been run at nearly 3 m.h. slower speed than was the very heavy length from Crewe to Carlisle. Here, however, we have two totally different classes of engines employed. And we have the apparent paradox of the slower speed over the easier road being done by the enormously more powerful locomotive, the engine from Euston—Adriatic—having two 14in. high-pressure cylinders and one 30in. low-pressure, with 175 lb. steam pressure and four 7ft. driving wheels, not coupled; while the engine from Crewe—Hardwicke—had two 17in. high-pressure cylinders, 150 lb. steam, and four 6ft. 6in. driving wheels coupled. In the absence of any allegations as to checks by signal in the former case, I venture to suggest that the inferior speed from Euston to Crewe may have been due to the fact that the engine had not a load sufficient to enable her to put forth her full power. In view of the immense loads so successfully managed under my own personal observation by one sister engine—Jeanie Deans, and of what I myself have seen another sister engine—Ionic—do on the Crewe-Carlisle run with a heavy train, I am inclined to suspect that this may possibly be the true explanation of that relative short-coming to Crewe when an average speed at least equal to the 67·2 m.h. run from Crewe to Carlisle should have been easily feasible. Indeed, if 67·2 m.h. could be done on a journey which included the ascent of such banks as Grayrigg and Shap, ranging up to 1 in 75, surely 68, 69, or even 70 should have been practicable to Crewe with no ascent steeper than 1 in 330, excepting for half a mile just after starting out of Euston, and if so, then Crewe should have been reached in about 2 h. 15 min. instead of 2 h. 27½ min., a saving of 12½ minutes.

If, then, those two slower lengths were done relatively as fast as the other two, and if that perfectly unnecessary stop at the Aberdeen ticket platform were cut out, it would manifestly be possible for the West Coast train to reach Aberdeen in 8¼ hours.

Turning now to the East Coast "record," the revised official figures do not appear to differ materially from those which I published in THE ENGINEER of August 30th. There are still certain unreconciled discrepancies, as in the case of the West Coast, but, as in that case, a very close approximation to absolute accuracy can be arrived at.

The official record of the times is as follows:—

Miles	Stations.		Offic'lly record'd times.	Aver. speed	Remarks
			h. m.	m.p.h	
—	King's Cross ..	dep.	8 0	—	G.N. engine No. 668, load 6 co'ches, slack Ouse Br. rep.
105½	Grantham	arr.	9 42	61·9	
		dep.	9 45		Engine No. 775, same load, slack over Selby Bridge
188	York	arr.	11 1	65·3	
		dep.	11 5		N.E. engine No. 1621, same load, slack over Durh'm B.
268½	Newcastle	arr.	12 25	60·4	
		dep.	12 27		No. 1620, same load, slack over Border Br. and thro' Berwick.
393	Edinburgh	arr.	2 19	66·7	
		dep.	2 21		
452¼	Dundee	arr.	3 21	59·2	N.B. engine No. 293, same load, several service slacks
		dep.	3 23		
523½	Aberdeen	..	4 40	55·6	No. 262, same load, several service slacks.

Here again we have to grapple with discrepancies. The times from London to Grantham have been variously given as 101 and 102 minutes; Grantham to York as 76 and 77 minutes; York-Newcastle, 79 and 80 minutes; Newcastle-Edinburgh, 112, 113, 114, and 115 minutes; Edinburgh-Dundee, 59 and 60 minutes; Dundee-Aberdeen, 76 and 77 minutes. So far as I can judge, the figures given in the accompanying "log" are the most accurate available.

On the East Coast, like the West, every run made, save one, was a record, or equal to record. In this case it was the length from York to Newcastle that alone failed to beat all previous performances over that portion of the road. It was, in fact, beaten by at least two former runs. The check over the bridge under repair at Durham, was common to all the trains. But it is worth noting that on the first night of the three when the concluding "rush" was made, when the racing train was stopped for three minutes by signal near Dalton, the actual running time, including that stop, was only half a minute longer than that of the record train. It is usual to allow three minutes for loss of time in starting and stopping. That would bring the "net" time down to 77½ minutes for the 80½ miles, without allowing for the two minutes lost at Durham Bridge. Taking the time from leaving York to passing Cowton, the station *before* the Dalton stop, and from passing Croft, the next station *after* starting again, to arrival at Newcastle, I find that the 76 miles occupied only 74¾ minutes. Thus, if that signal stop and the Durham check could have been eliminated, the run could certainly have been made in 75 minutes, or perhaps less.

Some surprise has been expressed that the Great Northern and its famous single-wheelers should have taken so low a place among the speed averages. The explanation given by the Great Northern authorities is, that up to the time when the "accelerated running"—in plain English, "racing"—was discontinued, no occasion had arisen for the Great Northern engines to be "extended" to their utmost power, but that in anticipation of further acceleration, some reserve had been kept in hand. Accordingly instructions were given to the drivers not to anticipate the prescribed arrival times in any material degree; and those instructions were duly acted upon. It is virtually certain, however, basing that calculation upon work actually done by the engines, that these 8ft. wheel engines could have made the run from London to Grantham in 95 min., and from Grantham to York in 71 or 72 min.; or, allowing 3 min. stop at Grantham, from London to York in 2 hours 50 min., or less.

The North British engines were debarred from showing higher averages by the special difficulties of their road; but their actual work was perhaps as meritorious *per se* as that performed by any of their rivals.

Summing up, then, the accelerations which were manifestly possible by the East Coast route, it appears certain that, even with the heavier loads run by the East Coast, fully 20 min. could have been saved between London and Edinburgh had the competition continued, bringing down the time from London within six hours. The extent to which time economy was possible north of Edinburgh would depend upon the special traffic arrangements that proved practicable.

Next we come to the respective loads. Here, again, there is great difficulty in arriving at certain results. The West Coast load has been variously estimated by competent authorities at from 60 to 83 tons. I believe, however, it was in reality as follows—according to the weights of the various classes of vehicles obtained from headquarters:—One sleeper, 25½ tons; one composite, 23½ tons; one van, 21½ tons; total, 70½ tons. All the vehicles were 8-wheeled. The East Coast load has been variously reckoned as from 101 to 105 tons, but I believe the correct weights to be—five 6-wheeled coaches, each 15½ tons; one 8-wheeled sleeper, 23½ tons; total, 101 tons. Further, the Great Northern tenders used in that service weigh 40 to 42 tons, the North-Eastern about the same, the London and North-Western 25 tons. Thus, the loads carried as far as Carlisle on the West, and Edinburgh on the East, were 95 tons and 143 respectively, exclusive of the engine, the bulk of whose own weight is, of course, the source of its adhesive power, and does not enter into a comparison of the loads hauled. The greater lightness of the North-Western tender is due, I need hardly explain, to the smaller tanks and less quantity of water carried, owing to the pick-up troughs being in use. These points are recorded simply for means of comparing the locomotive work performed, and of appraising its relative merit from the scientific view point. From the commercial view point it is sufficient that the loads of passenger-carrying and luggage-carrying vehicles weighed approximately 70½ tons by the West Coast, and 101 tons by the East.

Classifying the engines employed in the "race" since its inception in July, some rather curious facts present themselves. It might fairly be imagined that so great and unparalleled a trial of speed would naturally furnish an absolutely authoritative decision as to the type of locomotive best suited to fast running. Now, of the five companies which took part in the "race," the two Scottish ones—the Caledonian and North British—not merely employed each only one type of engine from first to last, but also both used practically the same class of engine originally designed by the same engineer, Mr. Dugald Drummond, who was successively locomotive superintendent on each line, and to whose main design his successors, Mr. Lambie and Mr. Holmes, have since adhered. That type, the 6ft. 6in. coupled, with cylinders 18in. × 26in. and leading bogie, does in effect all the express work of the two railways, and it did all the "racing" in this instance. The other three railways, Great Northern, North-Western, and North-Eastern, each used three different classes of engines. The Great Northern performed the bulk of the work with the late Mr. Patrick Stirling's oldest type of 8ft. singles, with outside cylinders 18in. or 18½in. by 28in., and 160 lb. steam, but also occasionally used the newer variety of these engines having 19½in. cylinders, 170 lb. steam pressure, and 20 tons on the driving wheels, and the 7ft. 7in. singles with inside cylinders 18in., 18½in., or 18⅞in. by 26in. The North-Western did most of the work with small 6ft. 6in. coupled engines, weighing barely 33 tons—and the record run was made with one of this class—but also used 7ft. 6in. singles for occasional piloting, and latterly employed Mr. Webb's 7ft. compounds between Euston and Crewe. The North-Eastern did most of its work with Mr. Wilson Worsdell's new 7ft. coupled engines, having cylinders 19in. by 26in., and 180 lb. of steam, but used the 7ft. 7in. singles, with cylinders 19in. by 24in., a good deal at first between York and Newcastle, and the compound singles with cylinders 20in. and 28in. by 24in., as pilots between Newcastle and Edinburgh.

Here there is variety enough to puzzle any judgment. Ten different classes of engines were employed. Can it be determined which did its work best? Is any moral of superiority in efficiency to be deduced from this notable competition?

In order of merit, as regards the highest average speed from start to stop, recorded during the last day's competitive running in each case, the respective engines stand in the following succession:—

		ft.	in.			Speed. m.h.	Load. tons.
(1	L. and N. W. ..	6	6	coupled ..	No. 790 ..	67·2 ..	70½
(2)	N. E.	7	1	coupled ..	No. 1620 ..	66·7 ..	101
(3)	C.	6	6	coupled ..	No. 17 ..	66·7 ..	70½
(4)	G. N.	8	1	single ..	No. 775 ..	65·3 ..	101
(5)	L. and N. W. ..	7	1	compound	No. 1309 ..	64·3 ..	70½
(6)	G. N.	8	1	single ..	No. 668 ..	61·9 ..	101
(7)	C.	6	6	coupled ..	No. 90 ..	60·5 ..	70½
(8)	N. B.	6	6	coupled ..	No. 293 ..	59·2 ..	101
(9)	N. B.	6	6	coupled ..	No. 262 ..	55·6 ..	101

The other classes of engines did not take part in the final and swiftest rush, but the newer Great Northern 8ft. 1in. singles, the Great Northern 7ft. 7in. singles, and the North-Eastern converted 7ft. 7in. singles, all exceeded averages of 60 m.h. from start to stop on various occasions.

Looking now to the roads run over, it must at once be admitted that the heaviest was that on which the highest mean speed was recorded, viz., from Crewe to Carlisle, which has a moderately stiff bank of about six miles approaching Coppull—1 in 100 to 1 in 330—and two very severe ascents, one of fifteen miles, averaging about 1 in 130, to Grayrigg; and the worst of all, two miles of 1 in 147, and 4½ miles of 1 in 75 to Shap Summit. There was also the service slack through Preston station. None of the other roads on which the best speeds were done were really severe, for the Caledonian best was between Perth and Aberdeen, which did not include the steep Beattock and Dunblane banks. The North British road, however, was much impeded by special difficulties in the way of curves, bridges, junctions, and single track. The Great Northern was seriously hindered by service checks at Retford and Doncaster, and by the very long and bad slack past Selby station and over the swing bridge. The North-Eastern had to contend with several banks, with the Morpeth, Berwick and Portobello curves, and with the bad slack through Berwick station. The North-Western length on which the slower run was made on the record night, had only the short but steep bank out of Euston and the slack through Rugby, in the way of obstacles, the gradients being as a rule very easy for the down trains.

Next arises the question, Which of the three trains that, in sporting parlance, were "placed" in the race—which took first, second, and third places—performed the most creditable work from a locomotive and engineering standpoint? It is not easy to appraise with exactness the relative merits of these three splendid performances. The North-Western 6ft. 6in. coupled engine ran at the highest average speed over the heaviest road for the longest distance of the three. But both that engine and the Caledonian 6ft. 6in. coupled, which is classed third in the list, conveyed a far lighter load than did the North-Eastern 7ft coupled, which, in fact, pulled about 50 per cent. more load, and yet attained within 0·5 mile per hour of the winner's average speed. That, however, was over far easier gradients, and so was the running of the Caledonian engine, which, moreover, drew the same light load as did the North-Western locomotive.

Further, the North-Eastern engine was enormously more powerful than the North-Western one—in fact, having 111 lb. of tractive force against the other engine's 88, for every pound of effective steam pressure in the cylinders, and having moreover 180 lb. of steam pressure in the boiler, against her rival's 150 lb., the North-Eastern racer may be regarded as possessing roughly 50 per cent. more power, as against the 50 per cent. greater load she pulled. So this leaves the North-Western engine with the full advantage of 0·5 mile per hour greater average speed over a very much more difficult road.

If, therefore, I were acting as judge in this race, after allowing for all the handicaps, I should be disposed to accord the victory to the London and North-Western engine No. 790—Hardwicke—but adjudging the North-Eastern and Caledonian engines a "tie" for a very good second place. It will be noticed that the winner's performance was relatively even finer uphill than down, the respective speeds to Grayrigg and Shap summits being, so far as I am aware, quite without parallel in railway records over grades so severe. At the same time there was very free and fast running down hill, although no excessive or "dangerous" velocity was attained. Superb work was done both up hill and down by the North-Eastern and Caledonian engines, which tied for second place; but they had easier grades in both cases than the comparatively small North-Western engine, which beat them by half a mile per hour.

It will naturally be asked, What was the absolute maximum speed attained during the fastest running? Here, again, only an approximate reply can be given, because no mechanical means of test—such as the Boyer recorder—was used, and but few attempts were made to test individual miles or shorter distances by the ordinary method, with stop watches or chronographs. Personally I was successful in obtaining a good many records of miles, or half or quarter miles; but it will readily be perceived, that this was a work of extreme difficulty in the pitch darkness of the night and travelling so swiftly.

On each route I obtained instances of a mile being run in 42 secs., which is equivalent to a speed of 85·7 miles an hour. I have no reason to believe that this rate was exceeded in any instance. At the places where I recorded these maxima, the time from one given point to another registered on the record night was the same as my own. No doubt the maxima intermediately reached were the same also.

This does not differ materially from the maximum which I recorded in the columns of THE ENGINEER a year ago.* The speed limit then—84·1 miles an hour—was the limit during the later race *on similar gradients*. The higher velocity was only attained on steeper descending gradients; that is to say, down 1 in 125, or 1 in 96, as against 1 in 200 in the other case.

Much indignation was expressed by some American engineering writers that I felt unable to accept as conclusively proved their alleged speeds of 102 and 112 miles an hour. But now comes my justification from America itself, and from one of the same engineering quarters whence proceeded the former remonstrances. After the English race concluded, a special effort was made in the United States to "break the British record." Practically, the result was a "tie." But the remarkable thing is that in this supreme American effort to lower the British record the engine used being, moreover, the same which was said to have attained 102 and 112 m.h.—the famous No. 999—the American official report states that the maximum speed was "about 81 miles an hour." Seeing that if No. 999 ever ran 100 miles an hour she would assuredly have done so on this supreme occasion, when, instead, she only attained "about 81," it is evident that we may safely dismiss that former casual unchecked timing by an irresponsible guard as being merely a pleasing little product of excited imagination. We may, at any rate, so regard it until the fact shall have been authentically established on the testimony of competent and trustworthy witnesses. Railway guards are admirable officers, but precise speed-timing is not their strong point. They have other and different duties to perform.

While my present observations have necessarily had relation mainly to the respective performances on the "record" night of each route, I may repeat a former remark that, marvellous as were these displays of speed even with "featherweight" trains, in my opinion they fell short, as locomotive work, of several other feats achieved during the progress of the "race," and even since its termination. For instance, that run of 52 min. 48 sec. from Carlisle to Beattock Summit—start to stop—with two Caledonian 6ft. 6in. coupled engines and 207 tons, passing Beattock station—39¾ miles—in 38 min. 14 sec., would not be easy to beat. Nor would a later run with one of these engines from Perth to Aberdeen—89¾ miles—in 93 minutes, with 160 tons behind the tender. It is amusing to observe the exaggerated fuss that is made about the Caledonian single, No. 123, on account of some very creditable performances in the race of 1888. These, however, have been widely surpassed by this year's work of the 6ft. 6in. coupled class; nor has No. 123 attained any higher maximum than they. There is, therefore, no reason whatever to suppose that No. 123 would have beaten or even equalled the achievement of No. 17 or No. 78 in this year's race, the latter having, on the last day but one, taken a train of four eight-wheeled coaches weighing 94 tons, from Carlisle to Stirling—117¾ miles—in 113 minutes—1 h. 53 min.—passing Beattock in 37 minutes, and Carstairs—73½ miles—in 70 minutes. This makes No. 123's record run of 75 minutes for the latter distance, with a load 18 or 20 tons lighter, look relatively small, fine as it undoubtedly was. Equally admirable was the run of 143 minutes from Crewe to Carlisle—141¼ miles—made by a 7ft. compound, with a 6ft. 6in. coupled as pilot, and a load of 234 tons — equal to fully nineteen 12-ton coaches — including a very smart ascent of the Shap bank; and certainly as fine as any was the achievement of one of the newest Great Northern 8ft. singles—having 19½in. cylinders, and 170 lb. of steam—which, starting from Grantham six minutes late owing to previous blocking of the train, stopped at York 1½ minute before time, having run the 82¾ miles with three slacks—a very long and bad one at Selby—in 80 min. 31 sec., hauling a load of eleven vehicles, weighing 186 tons. Nor was the effort of the North-Eastern 7ft. 7in. single much inferior when the distance of 80¼ miles from York to Newcastle was covered in 79¾ minutes, with a load of 134 tons, in spite of two minutes being lost at Durham Bridge, and another through a check at Gateshead. In that case, too, the train left York two minutes late and reached Newcastle ten minutes early. All these performances came under my personal notice, so that I am able to vouch for their authenticity.

It is almost impossible to avoid facing, in conclusion, the very reasonable question that must inevitably suggest itself:—After duly considering all these locomotive achievements, what is the deduction as to superiority of type for express duty? I regret very much that I can only return the lamentably feeble answer that there appears to be little or nothing to choose among the various types employed. Yet this seems really the only reply which can honestly be given by any unprejudiced observer who has impartially studied the results attained. There are no apparent grounds for doubting that any of the engines used in the "race" could have done as well as any other with a load proportionate to its nominal power; and above all, the race appears to have rendered still more abundantly clear the conclusion which I deduced previously in these columns from other experiences with British locomotives, that coupled engines will run just as fast as singles, and that singles can pull just as heavy loads as coupled and climb banks equally well, provided that in each case the loads and gradients are proportioned to the available tractive power.

As to the relative cost in working expenses at which all this splendid work is done, no authentic information is accessible; but it certainly does appear, so far as known results go, that no excessive expense was caused by the faster running. One thing at least is certain, that all the types of locomotive in use in our best British express-work are so admirably suited and proportioned to the duty they have to do, that it would be a task of extreme difficulty to award the palm to one as against another for merit of accomplishment.

THE GREATEST AUCTION SALE.—The world's greatest auction sale occurred at Topeka, Kan., on December 10th, when the vast property of the Atchison, Topeka, and Santa Fe Railroad Company was sold to Messrs. Edward King, Charles C. Beaman, and Victor Morawetz, representatives of the Re-organisation Committee. The reading of the notice of sale occupied thirty minutes. This done, Judge Johnson said that, in pursuance of the notice of sale just read, he offered the property to the highest bidder. "What am I offered?" the auctioneer asked. "I offer 60,000,000 dols.," said Edward King, in a low voice. "Do I hear any more bids?" cried Judge Johnson. "Once, twice, the last call. The property is sold to Edward King, Charles C. Beaman, and Victor Morawetz." This ended the greatest auction sale ever known, and the crowd dispersed to the Federal Building, where Judge Caldwell held a session of court to confirm the sale. As indicating the immensity of the sale, it may be stated that the system proper embraces 4670 miles of railroad, on which are now being used 864 locomotives, 28,187 freight cars, and 584 passenger cars. The system has practically been built within the past twenty years, the extension into Chicago being only about seven years old. Originally the line was intended to parallel the old Santa Fe trail, over which was transported the greater part of the commerce of the plains. Over 100 days were required to reach Santa Fe by freighters over this historic trail, the same route now being covered in twenty-eight hours by the road's overland trains. This commerce of the plains grew to such proportions that in 1858 there were on the trail 2500 men in some way engaged in this traffic. In that year there were registered at Council Grove, Kan., 1827 wagons, 429 horses, 5316 mules, 15,714 oxen, and 67 carriages or passenger vehicles. During that year there were 9608 tons of freight carried over the route, equal to about 500 car loads. There were over 2,500,000 dols. directly invested in this business, with another 1,000,000 dols. as an incidental investment. The trail started from Fort Leavenworth and from Independence Landing, formed a junction just below Lawrence, struck the Arkansas near where Great Bend is now situated, following the river 100 miles, crossed and passed through the sandy country for about sixty miles to the Cimarron, which stream it followed to near the south-west corner of Kansas, thence in a general south-westerly direction to Santa Fe, 780 miles from Independence Landing. The present line of the Santa Fe follows practically the same route of the trail. Great opposition was made by the freighters to the building of the line. The history of the management of the company since it was first organised has been a most varied one, and so many bright railroad officials have stepped to its head with great reputations as managers and had to retire beaten, and oftentimes with discredit to themselves, that the road has come to be known in railroad circles as a "man killer." In President E. P. Ripley, however, and Vice-Presidents D. B. Robinson and Paul Morton, an exceedingly able group of practical and progressive railroad men is now placed in control of this largest railroad in the world, and it is the confident expectation of those who know their ability and the resources of the road that the troubles of this great company are near an end.—*American Engineer and Carbuilder.*

STEAM LOCOMOTIVES ON COMMON ROADS.

By W. FLETCHER.

(Continued from page 86.)

THE compound road locomotive is coming into more general use. It has its advantages—by its use the boiler can be reduced in size, a saving in coal and water is also effected, and the noise from the exhaust in the chimney is suppressed, which is a valuable feature in its favour. If a compound engine is selected the cylinders will be 6¼in. and 10in. in diameter, and 12in. stroke. It is usual to fit the compound cylinders of road locomotives with an auxiliary valve, so that high-pressure steam can be made to enter the valve chest of the low-pressure cylinder, and both the cylinders exhaust into the common exhaust pipe, the compound principle being suspended for the moment when the engine has to start with a heavy load on an incline. As soon as the engine is running up to speed the auxiliary valve is closed. The steam chests should be placed outside so as to facilitate the examination of the slide-valves. Compound road engines with tandem and Woolf cylinders are used, but I should specify a side-by-side double-crank compound engine. A relief valve should be fixed on the low-pressure valve chest. A sleeve might be fitted on the exhaust pipe so as to further reduce the noise. As this engine is not intended for driving machinery from the fly-wheel, no governors need be provided.

The link motion reversing gear must be massive, with plenty of wearing surface, and deeply case-hardened. The lubrication of excentrics, the slide valve, and link motion must be properly carried out. Cast iron excentric straps are mostly used, and when properly turned, with all the corners rounded off, with careful attention they will run almost without wear. Circular-bored guides are often used now for the crosshead in lieu of guide bars. Little more need be said about the engine work; the chief consideration rests with the wheels and the driving gear. This brings me to the subject of the driving wheels. In Mr. John McLaren's paper[7] the ordinary road wheels are illustrated, but these are not suitable for this purpose. The driving wheels I should propose would be made of boiler plates and angle iron, in much the same manner as the rubber-tired wheels were made a few years ago; then spur rings would be riveted near the rim or tire of the wheels; both wheels would be driven from separate pinions on each end of the second countershaft. The main axle would in this case be fixed, the driving wheels would run loosely on it; the axle might be lighter than usual, as no power would be transmitted through it. Wrought iron case-hardened bushes would be secured in the naves for the wheels to run on; the axle ends would also be case-hardened. If these bushes are made a good length they will run for years without giving any trouble, provided they are well lubricated. This method of transmitting the power to the wheels is adopted for the sake of lightness. It will be necessary for the compensating gear to be made from small patterns, and be mounted upon the second countershaft; the rest of the gearing will be dealt with presently. The remaining part of the driving wheels will be made of india-rubber and wood. Possibly no driving wheels have answered so well for quick running as the rubber-tired ones, but as this type of wheel is too costly we must use less india-rubber, and place it around the cast iron nave of the driving wheel, as suggested by Mr. Pendred, also illustrated in Mr. McLaren's paper. Impinging upon the rubber will be blocks of wood endways of the grain, with iron hoops on the edges, with suitable provision for allowing the wood blocks to move endways, but securely kept in their places circumferentially. No driving stress would pass through these wheels, as the spur rings would be riveted near the rims. A wheel of this form, if properly made, would answer for light road locomotives.

If Boulton's wheels could be made of wrought iron plates they would answer. A small amount of elasticity in the wheels would be sufficient to take off the concussion and give greater adhesion; the disc wheels would afford the same flat surface on the road that the rubber-tired wheel did. In addition to an ordinary strap brake on the compensating gear, it may be advisable to fit a pair of brake blocks to rings on the wheels for hilly districts, to be used in cases of emergency. I should make the driving wheels 6ft. 4in. diameter and 1ft. 4in. on face.

The gearing will be made entirely of cast steel, the cogs will be carefully pitched and trimmed, and the teeth must not be of a very coarse pitch. The first and second motion gearing will be arranged between the bearings of the crank-shaft and countershafts, inside the box brackets. If a compound engine is employed, the gearing cannot be so nicely arranged, as the two cranks and four excentrics occupy too much room. The inside gear engines possess several advantages: the gearing runs with little noise, the engine can be made narrower than usual, the bearings are more fairly worn, and what is of the greatest importance, the gearing is maintained rigidly in truth. All the gearing will be covered in with guards, so as to protect it from dust and suppress the noise. Two travelling speeds will be provided for. A ratio of 6 to 1 for the fast gear, and 10 to 1 for the slow gear, is decided upon. As a general rule the quick travelling speed would be used, the slow gear being intended for cases of emergency, such as mounting inclines, traversing bad roads, or passing through crowded thoroughfares. These ratios will give a speed of six miles an hour, and ten miles, the engine running at 280 revolutions per minute; of course, any speed lower than these could be run when required.

I must now deal with the method of mounting this spur-geared engine on springs. It is very evident that a small amount of movement, due to the action of the springs, will be required for an engine running at the speeds named, and particularly as we have provided a certain amount of elasticity in the driving wheels. The springs must be so arranged that they can be adjusted to give the required range for taking off the concussion. If more than ¾in. play is given, the swaying of the passenger engine on some roads would become unpleasant. Three different methods of mounting engines on springs are already shown; these, however, are designed for heavy engines, in which the driving power passes through the main axle. It has already been said that the compensating gear will be fixed on the second countershaft, but the spring arrangement can be carried out on fairly simple lines. Good provisions for driving the winding drum on the axle can be made without complication.

The usual tender and extra tank under the boiler barrel are shown in the sketch of passenger train, Fig. 34, but if necessary, a separate tender could be mounted on a pair of wheels and attached to the foot-plate of the engine. A spare tender with tank filled and fuel replenished, could be taken on

quickly, and the empty one left behind; this would save time on the road, clean water could be secured, and the total weight of the engine would be reduced by one ton. The draw-bar would be attached to the hornplates of the boiler. A spring draught iron is very useful for taking off all jolting when the engine starts with a load. In addition to the feed pump driven by an excentric on the crank shaft, an injector should be supplied, so that the boiler could be fed while the engine was standing. Both these appliances would be within the reach of the engine driver. A large water lifter and hose pipe is an essential appendage for the kind of tender shown on the drawing.

The steerage will be actuated from the foot-plate, but instead of the usual chains and chain barrel, I should recommend a large worm and rack under the boiler barrel. The rack would be guided and thus kept properly in gear with the worm. The connection between the rack and the front axle must be of a ball-and-socket arrangement, to allow for the up-and-down movement of the front axle. The front of the engine would be mounted on springs. A foot-board would be provided on the side of the boiler for gaining access to the engine for oiling, &c. A neat cab is erected over the tender and the shaft end of the engine; the windows are arranged so that a good look-out can be obtained. The head lamp must cast a good light on the road in front of the engine. All the handles for starting, stopping, and reversing the engine, for opening and closing the cylinder cocks, for starting the pump or the injector, for opening the sliding fire-door, for putting the road gear pinions in and out of gear, for opening and closing the ash pan doors, for applying the brake, for sounding the whistle, and for starting the water lifter, should be placed as conveniently as possible within reach of the engine driver. Two men will control the engine, one as driver and one as steersman. Another man will be required to take charge of the omnibus.

I have touched upon the details of importance composing the road locomotive proposed for the running of light road trains. A drawing in side elevation is given of the train, Fig. 34. It will be seen that the working parts of the engine are hidden from view; the fly-wheel is of the disc pattern of small diameter, and every possible care will be taken to remove any objectionable features that are liable to frighten horses. Care will be taken that the road train cannot truthfully be termed a nuisance by persons who object to the use of machinery on roads. The engine is shown drawing an omnibus mounted on springs, which will seat twenty to thirty passengers; there is shown also a light spring four-wheeled van for carrying market produce, parcels, &c., to the railway station or market town. The engine will not vary much in appearance for different districts. It is believed the character of the train will often differ; it may be altered to suit the requirements of the neighbourhood through which the train shall run. The omnibus may give place to a light-covered wagonette, so that more room and power would be available for hauling merchandise.

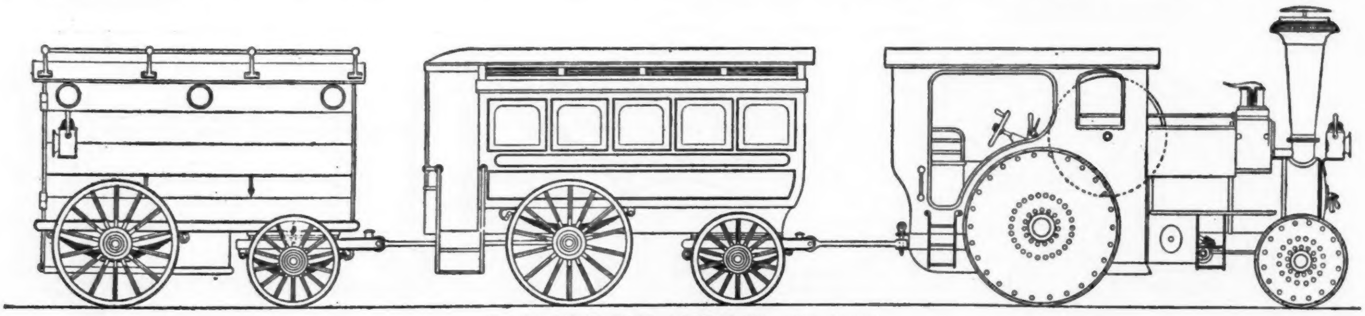

Fig. 34—LIGHT ROAD LOCOMOTIVE AND TRAIN

Mr. McLaren has referred to the legal restrictions relating to road locomotives,[8] but more may be said on the subject, as the laws affect us to such an extent that the traction engine proposed for the conveyance of passengers and light goods would not be permitted to run except at a crawling speed. The time has surely arrived for these Acts of Parliament to be modified, or removed altogether. Instead of giving the simple road locomotive fair play, engineers are at the present time discussing a far more costly means of transport, viz., light railways or tramways. This is one of the proposals which has been suggested for helping the farmer to tide over the depression. Such railways may be required in some districts. It has been said, however, that their adoption will only add to the farmer's burdens. It has been urged that they never can be remunerative. The advantages of light railways have been over-estimated, and without question the means of transport I am dealing with has been entirely overlooked.

I do not for one moment believe that the road locomotive can compete with the light railway for speed and long distances, but I do believe that if it were freed from the all but prohibitive laws its utility would be surprisingly increased. So many people entertain the idea that road locomotives are only suitable for drawing heavy loads at very slow speeds. It must be remembered that the law compels them to travel along the roads at this tedious pace, and because of this enactment they are made exceptionally heavy so as to draw as much weight as possible.

Our legislators, and not our engineers, are to blame for some of the greatest disadvantages of the present road locomotives. I cannot stop to enumerate them, but one is the extreme weight of the engine and the trucks, and another is the great width of the train. If quicker speeds had been permitted, smaller engines and trucks would have been used in preference to the heavy ones. With smaller and lighter road locomotives there would have been less risk of breaking bridges, reduced wear and tear to the roads, less risk of damaging old buildings near the road, and the road train would have been narrower, thus allowing more room for passing vehicles. Engineers and owners would gladly introduce a smaller road locomotive and train if they were allowed to run them at six or eight miles an hour in the open country.

Very few people know what a properly constructed road locomotive can do in the way of quick running, as such engines have been rarely tried in England. The arguments raised against their use for this purpose are all based on our present engines that are built for, and used for a totally different service. The remarks made in favour of quick-running traction engines are mostly based on experience. Messrs. McLaren's parcel service in France shows what can be done. Lyons and Grenoble are nearly seventy miles apart. Each engine covers this distance in the night, and runs for hours together at eight miles an hour, over the worst possible roads and up some steep gradients.[9]

Undoubtedly the road locomotive and train that have been described would in many cases answer all the requirements for the conveyance of passengers and goods at economical rates in sparsely populated districts out of the reach of the main railway line. The roads are ready, and we have the engines[10], so that this means of communication could be put into operation as soon as the laws are altered, without costing an extra penny to the ratepayers of the district through which it would travel. The engines would be narrow, light, noiseless, and constructed so as to travel on any ordinary road, mount steep inclines, turn sharp corners, and run close to the farmyard gate. If a light railway or a tramway was to run through a parish or village containing a number of farms in the neighbourhood, it would only touch a small number of these homesteads; the greater number to reach the railway must use their horses, carts and men. Whereas a road locomotive could enter the field or farmyard, take or deliver produce, and could serve any number of farms in the district.

Supposing two road trains were running regularly between a group of villages: on certain days of the week a different route could be taken, so as to put every doorstep in touch with the nearest market town and its main line railway station. A number of light road trucks would be left at any point of the journey, to be called for after they had been filled or emptied, so as not to keep the engine waiting. Such road engines are now helping the farmer, are working satisfactorily under the present fierce opposition and restrictions, doing such work as just described.

Road locomotives are appreciated on the Continent and in the Colonies. Our military authorities have proved the advantages of the engines when running at four miles an hour, and would gladly avail themselves of a greater number of engines if they were allowed to travel at eight miles an hour. It may safely be predicted that if the hindrances were removed, and the road locomotive were given fair play, this cheap and efficient means of transport would not only convey goods as at present, but passengers would be conveyed also. Many road trains would spring into existence, and bring life and activity to many a remote hamlet and farm. Other advantages would accrue that are not thought of. Many of our main roads are not suitable for tramways; to adapt them for laying the rails would entail an enormous expenditure of money. No one would think of allowing light railways to run on any of the roads, and to use valuable land for such a scheme appears to be a wasteful procedure. Instead of laying tram lines, let a tithe of the amount be expended in making and keeping our highways in thorough repair.

It appears to be so unreasonable to place every hindrance in the way of a simple system of communication which is ready to hand, and at the same time seek the means to build up an extravagant system that farmers cannot pay for. If Mr. Price Williams' estimate is correct, the cost of every mile of light railway would purchase two road locomotives, two omnibuses to carry twenty or thirty passengers, two covered vans and four light wagons, all mounted on springs and connected by spring draw-bars.

It must be remembered that very likely the large railway companies will construct some light railways as soon as they are decided upon. Not only so, but should light railways be constructed by private companies, many of them would probably come into the hands of the great railway companies. Both these contingencies must be resisted, otherwise no advantage would be gained by any number of light railways.

The railway interest is very powerful in the country, and this gigantic system is gaining possession of water-ways, and is seeking to gain power over the roads. One large railway has already forbidden traction engines to run over their bridges. The roads were free for all kinds of traffic before the railways came into existence. If the railway company cut one of these roads, they must provide a bridge strong enough to carry all loads, and they must not interfere with any vehicle that has occasion to travel along the road and cross the bridge. The railway companies surely possess no right to interfere with the users of the roads; their duty is to carry freight and passengers, and not to interfere with pre-existing rights as they are now endeavouring to do. We must retain our roads for the free use of the people, and not allow the railway companies to have any control over them whatever.

There are 8000 traction engines at work in this country. They are sufficiently harassed by the injurious laws that are in force without the railway companies seeking to add another burden. Can the railway companies forbid us to use a bridge over the railway, or canal, that is part of a main road, or even a level crossing that answers a similar purpose?

This much has been said respecting the railway interference with the traffic over the public roads, in the hope that this unjust proceeding may be nipped in the bud.

The main roads of this country are practically free, and must remain so. The engine and train that I am proposing to run on these roads will be mounted on springs, and will come under the term of ordinary traffic, as they will not injure any well-made macadam road. Let every effort be used to remove the burdensome road engine laws, and before two or three years have elapsed the problem of cheap transport will have become an accomplished fact, brought about by private enterprise and private money.

COAL DUST FUEL.*

THE use of coal dust as fuel, to which the attention of the technical world has lately been directed, is not—as might be supposed—a novelty. As far back as 1831 an English patent was taken out for an apparatus for burning finely divided combustible matters, and by the end of the sixties the number had increased to over a score. The great drawback in the way of the successful employment of these processes was the liability of the feed pipes and furnaces to choke up, and the difficulty of getting the fuel into a regular state of division. The first to overcome these difficulties was the process of Whelpley and Storer—patented in America in 1866—for roasting ores containing sulphur, whereby a finely-divided mixture of ore and coal was blown into a vertical furnace. At about the same time Crampton began his researches in connection with the same subject, which led to the erection in 1869 of a furnace at Woolwich for heating iron fagots, and subsequently of a puddling furnace, in both of which dust fuel was consumed. Crampton's apparatus consisted of a hopper, with a couple of screw-shaped stirrers, by which the coal dust was loosened and conveyed to the outlet, where it passed between a couple of feed rollers—the upper one adjustable for regulating the feed—into a funnel, whence it was blown into the furnace by an air current from several narrow tubes. For pulverising the coals, Crampton employed ordinary millstones. Notwithstanding the great expectations entertained of the development of this process, it seems to have fallen into oblivion until in 1892 Carl Wegener, of Berlin, began to experiment anew in this direction. He was quickly followed by Schwartzkopff, Friedeberg, Ruhl, and De Camp, all of whose methods are based on Crampton's process. The chief task consists in loosening the coal dust and conducting the material and air supply to the furnace.

The furnace is lined with fire-brick, and frequently provided with a bridge to retain the ash and unconsumed fuel. Frequently it is attempted by means of baffles to drive the gases in a zigzag direction. This, however, did not lead to satisfactory results in Crampton's apparatus, nor in that of Ruhl later, owing to the liability of the narrow spaces to become choked.

To start the combustion a small fire of wood is made at the bottom of the furnace, and when this is well alight coal dust is scattered over it from time to time, until the fire-brick walls are hot enough to ignite the coal dust blown in from the feeder. From this point all that the stoker has to do is to control the admission of air and dust, the ashes being only removed once a day.

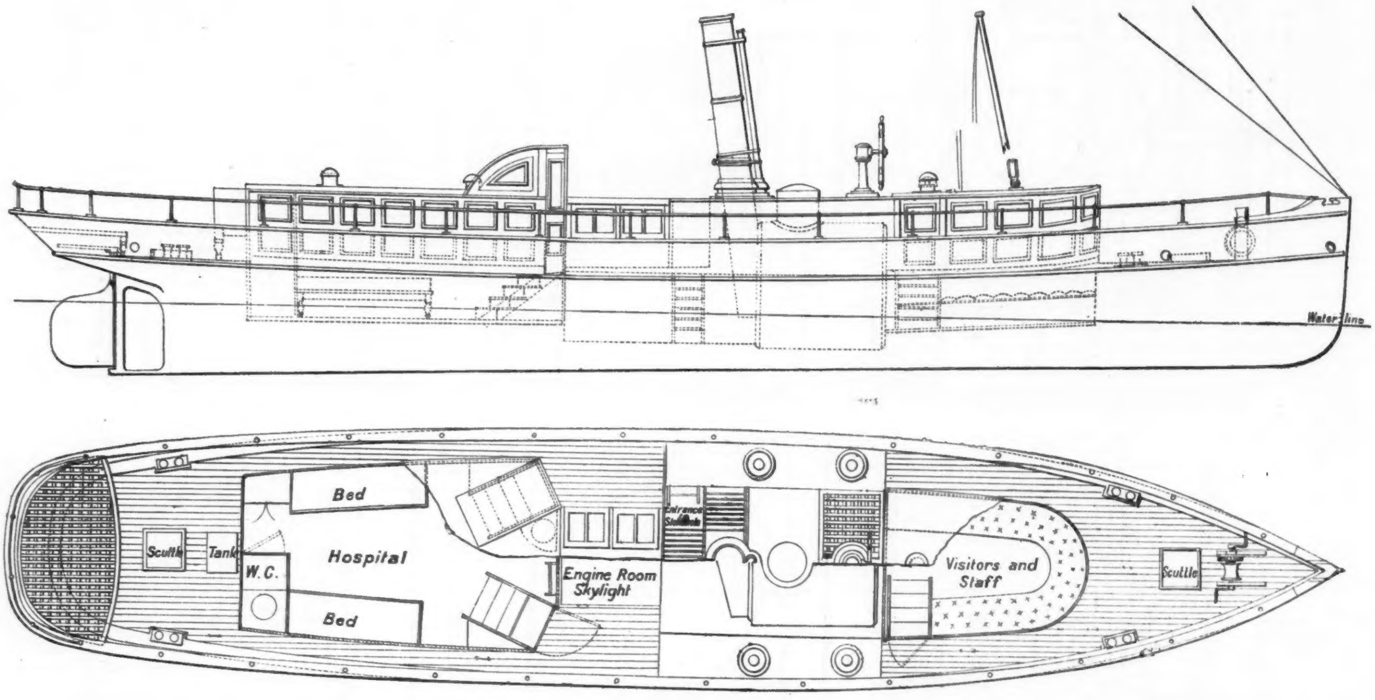
STEAM LAUNCH FOR AMBULANCE SERVICE



The only machine requiring no motive power is that of Wegener. The air is drawn in by the up draught of the chimney and rotates a horizontal fan, the axis of which, prolonged in an upward direction; moves a sieve, and thus loosens the coal dust in the hopper, causing it to fall on to a double cone, where it meets the air current, and is thereby blown into the furnace, the draught being increased at this point by the constriction caused by the cone. The current can be regulated by a valve at the base of the pipe, and an extra pipe is fixed at the side for increasing the air supply when necessary.

In the Schwartzkopff apparatus the air is drawn in by the chimney draught through adjustable openings, but the passage of the coal dust to the furnace is accelerated by a revolving wire brush. The outlet of the hopper is formed in two parts, one of which is regulated by a screw. The other consists of a spring, the end of which is struck by a hammer at each revolution of the brush, whereby it is forced up against the coal, and assists, by its return spring, in loosening the mass in the hopper.

Ruhl's stoker forwards the coal dust by means of an archimedean screw through an adjustable aperture into the blast pipe, the current being also in this case induced by the chimney draught. Any fuel not dropping into the aperture is taken back by a second screw.

De Camp's arrangement necessitates the use of a special fan to draw the air and dust fuel into the furnace, but possesses the advantage that it can be erected at a convenient distance away from the furnace. The coal is conveyed from the hopper by a screw and falls into a revolving sieve forming the intake of the fan, from which it is driven by cogwheel or belt gearing.

In Friedeberg's system no movable parts, beyond the fan—which can be situated in any suitable position—are necessary. The air current is passed through a vertical pipe, and is divided at the point where this is bent at right angles, the one portion going direct to the furnace, while the other is led through a chamber into which the coal falls from the hopper, and carries away the fuel into a cone-shaped delivery pipe, where the divided currents are re-united. Three throttle valves are provided for regulating the delivery, and the whole apparatus swings on the vertical pipe so as to be easily moved away from the furnace doors.

The chief engineer—Hr. Schneider—of the Berlin Boiler Inspection Association, has tested the Wegener and Schwartzkopff stokers, and the chief results of the experiment are given in the subjoined table. Of the two boilers heated by the aid of the Wegener apparatus, one was a double flue boiler surmounted by a tubular boiler, the connection being made by means of two pipes. The hot gases circulated through the flues passed along the outer walls of the lower boiler into the tubes of the upper one, and finally over the steam chamber. The heating surface amounted to 125 square metres, the furnace occupying a space of 2·8 square metres. The second boiler had a cylindrical fire-box and heating tubes; the outer walls were not in contact with the flame, but were coated. The dimensions of the furnace were 1·95 square metres, and the total heating surface 78 square metres. In only the first five experiments was the evolution of smoke determined, and was generally small, but could not be entirely prevented. A drawback incidental to the Wegener apparatus is the noise made by the blast and fuel.

The boiler fed with the Schwartzkopff stoker is one employed for testing safety valves, &c., and had to be kept unmounted, thereby suffering considerable loss of heat by radiation, &c. There were two flues, the one containing the furnace, and the other divided longitudinally by a fire-brick partition. The production of smoke was exceedingly minute. (Table A, page 106.)

These figures show that the employment of coal fuel in the state of dust gives an advantageous result from the point of view of the utilisation of the combustible material, in addition to which may be reckoned the diminution of smoke, as well as the minimum excess of air necessary to secure combustion—owing to the intimate admixture of air and fuel—and the regularity of temperature obtained in the furnace. Little attention is required, being limited, while the apparatus is working to regulating the admission of air and coal dust, and the heavy labour of shovelling coal is altogether avoided. Besides, the fire can be quickly extinguished in case of danger. Other advantages are—protection of the boiler and facility of regulating the fire according to the demand for steam, and also the fact that any combustible capable of conversion into powder can be utilised. Experiments have shown, however, that very ashy coals give rise to some inconvenience.

The instigator of the preceding tests asks why, in view of its manifest advantages, coal dust firing is not more largely practised. He considers the circumstance that most of the apparatus projected require mechanical power to be unimportant, but points out that the large quantity of ash deposited in the flues may be disadvantageous to the working of the system, which is, moreover, unsuitable for locomotive and marine engines.

Probably the greatest difficulty to be overcome is the production of the coal dust. This is generally accomplished by disintegrators, and a new centrifugal roller mill is said to give good results. The cost of the operation is somewhat high, reckoned by the inventor at about 1s. 8d. per ton, but would probably come out even more in practice.

STEAM LAUNCH FOR AMBULANCE SERVICE.

THE managers of the Metropolitan Asylums Board recently invited tenders for a screw steam launch for the river ambulance service. The above engraving shows the general arrangement of the vessel. It is intended to run her at 10 knots per hour. The following are the intended dimensions:—Length between perpendiculars, 60ft.; breadth, 12ft. 6in.; depth, 4ft.; draught of water when fully equipped to be a mean of 2ft. 8in. The hull is built of Siemens-Martin mild steel throughout to Board of Trade requirements for passenger certificate. She is built in five compartments. In the fore part of the vessel is a cabin for the accommodation of the staff and for visitors proceeding to visit patients in the hospital ships in Long Reach, Dartford, and is capable of accommodating about twenty persons. In the after part there is a cabin fitted up as a hospital, with four berths—two being fixed and two portable—and with all the necessary requirements for carrying four recumbent patients. Both of these cabins are heated with steam, and are provided with suitable skylights and all the necessary fittings for a boat of its class.

The machinery is fixed amidships, and is of the triple-expansion type, with surface condenser, and capable of driving the vessel at a speed of 10 knots. A water-tight trimming tank is built at the fore end of the vessel, of sufficient capacity that when filled with water it will bring the vessel to an even keel of 2ft. 8in. The top rail is of teak 3½in. by 2in., fitted all round with galvanised iron stanchions, with galvanised iron tubular rails passing through them. The deck is of 2in. pine, and fitted with bollard, windlass, &c., to lift anchor, metal chain conductor. The fore cabin is of teak, with American pine match-lining down to the floor. This cabin is provided with locker seats all round, upholstered with horsehair and American cloth. The cabin is entered on the starboard side by a teak ladder having brass treads. The top of cabin is of ¾in. teak grooved and tongued, and is covered with 4 lb. lead.

The funnel is hinged. The steering gear consists of a polished teak wheel, brass mounted, bearing the vessel's name. The mast is a light hinged pole mast, provided with fitting for carrying the steaming light. The vessel is provided with a one hundredweight anchor and 30 fathoms of ⅝in. chain cable, one metal ship's bell with name of vessel on it, one patent telegraph from deck to engine-room, and one siren.

If the speed at the steam trials does not come up to 10 knots per hour, deduction will be made from the contractor as follows: $\frac{1}{10}$ knot below 10 knots per hour, £10 will be deducted; $\frac{2}{10}$ knot, £20; $\frac{3}{10}$ knot, £40; $\frac{4}{10}$ knot, £80; $\frac{5}{10}$ knot, £150. The contractor has to provide engineer for one year, and to keep the vessel insured for six months, that being time allowed for building,

SOME RAILWAY SCHEMES OF 1846.

IN a facsimile of its first edition of January 21st, 1846, the *Daily News*, on the occasion of its jubilee, brings to light many curious old bits of railway news. The fourth column of the front page begins with an advertisement, signed by George Hudson, for tenders for the re-construction of the Whitby and Pickering Railway. This little known but most interesting line was laid out by George Stephenson, and with the exception only of the Leeds and Selby—1834—was the first railway in Yorkshire. A single line all the way, horse-power was the only mode of traction upon it, save upon an incline 1500 yards in length, and varying in steepness from 1 in 10·9 to 1 in 28·4, or about 1 in 15 on the average. A tank truck, being filled with water at the bank top, was run down one side of the slope, pulling the train up the other by a 4½in. rope running in sheaves. The inclines, and in fact most of the lines, were full of curves, some of them so sharp as ten or twelve chains radius. Beyond the incline just named the line still rose, but easily, the summit being precisely half-way between the termini and situated on a treacherous bog. After his experience at Chat Moss, however, it must have been a bad bog indeed that would have daunted George Stephenson, especially with a horse line. Many of his favourite peculiarities of construction were here displayed—stone block sleepers, fish-bellied rails, 35 lb. or 40 lb. per yard in weight; the gauge of 4ft. 8½in., an absurd castellated entrance to the solitary short tunnel. Some of the rails had half-lap joints, others were scarfed, the 15 lb. chairs resting on blocks containing four cubic feet of stone. A vehicle, built like a stage coach of enlarged dimensions, conveyed passengers over the 24 miles in about 2½ hours. There were also a few open conveyances, and it was found that one horse could draw four tons at ten miles an hour on the easy parts of the line.

The principal object of the Whitby and Pickering Railway, which was opened on May 26th, 1836, was to bring down stone and lime from Leaserigg and Grosmond for shipment at Whitby, and to carry coal in the opposite direction to Pickering and the places near it. Other works were established on the line, but though it only cost £5000 per mile it never paid, and was purchased in 1845 by the York and North Midland Railway Company, which soon connected it to its Scarborough line, doubling the track and adapting it for locomotives. The incline between Grosmont and Goathland, however, was worked by a stationary engine instead of water balance till July 1st, 1865, when the Whitby deviation was opened and substituted for it. An interesting account of the line and its opening, with views of the scenery, was published in 1836 by a Mr. Henry Belcher.

The first number of the *Daily News* also contains a lengthy prospectus of the Direct Northern Railway, with a comparison of the distances by it and the rival scheme of the London and York. Most of these figures are rather too good to be true; for instance, 176 miles to York, no less than 12 miles shorter than the present very direct line. Hudson was interested in the old route to York by Rugby, Derby, and Normanton—218½ miles—and fought the Direct Northern in the session of 1846 with his utmost energy. It was to no purpose though; the new line got its Act, amalgamated with the London and York, and became the Great Northern of to-day. A site in Holborn, between Furnival's Inn and the corner of Gray's Inn-road, was to have been the terminus of the Direct Northern, and separate lines for goods and passenger traffic seem to have been intended.

Besides being chairman of the Midland and the Eastern Counties, George Hudson was also head of most of the older lines now forming part of the North-Eastern. With all his faults he was an extremely able railway administrator, and until he got too many irons in the fire, invariably did well for the lines he controlled. Like the Stephensons he could see straight, and never for a moment was led away by the showy seductions of the broad gauge or the atmospheric system. A long report of a special meeting of the London and South-Western, in the paper in question, contains some interesting reminiscences. The company had a strong desire to make an extension from Nine Elms to London Bridge, although the calamities following the railway mania induced it to stop short at Waterloo in 1848. Plans involving some six millions of money were in hand for lines from Basingstoke to Penzance, much of which was carried out later on by separate companies, now absorbed by the South-Western. Broad gauge and narrow were meeting, or threatening to meet, in the Yeovil and Weymouth district, and the Duke of Wellington was in a fearful rage at the Great Western bringing "a d——d railroad" through his estate between Reading and Basingstoke.

In 1846 some of the South-Eastern trains started from Bricklayer's Arms, the present goods station, and of course went round by Redhill to Dover. A "courier's carriage" was run on the 11.0 p.m. goods for the convenience of early voyagers, but from Folkestone, at any rate, there was only one boat a day to Boulogne, and a bi-weekly service between Dover and Ostend.

Altogether, this old *Daily News* is a delightful record of the days when Hudson, Cobden, and Peel were probably the greatest men in England.

END OF THE ENGINEERING DISPUTES ON THE CLYDE AND LAGAN.

IN view of the many disappointments and kaleidoscopic changes which have characterised the wages dispute in the engineering trade of the Clyde and Belfast, it was only natural that there should be some inclination to reserve congratulations over the termination of the deadlock until the fact was actually beyond question. It is therefore with assurance made doubly sure by the actual resumption of work all round, that we can now regard and speak of the lamentable dispute as a thing of the past. Since Monday of this week the resumption of work in all the engineering shops of the Clyde and the Lagan has been gradually effected, not, of course, without the little jars and hitches only natural after so long a stoppage of the industrial machine, and to-day operations are being carried on with as much briskness, and perhaps greater spirit than before the dispute was commenced. The terms of settlement, while not all that the men had hoped for, and at first insisted on getting, are yet on the whole a satisfactory termination to the contest, especially seeing that they involve the acceptance of conditions as to a time-agreement in wages which will go far to prevent any repetition of such hurtful and harassing disputes in the future.

The means by which a satisfactory termination has been put to the industrial dislocation were not latterly any more free from delicacy and difficulty than earlier efforts, although an anxiety, only poorly disguised, on the part of the men to have done with idleness, helped materially to a settlement. Briefly told, negotiations proceeded thus:—Lord James of Hereford, and Lord Provost Bell, of Glasgow, whose efforts to bring about a settlement of the dispute have been unceasing, quietly but promptly availed themselves of the opportunity afforded by the third meeting of the Employers' Federation at Carlisle on the 16th instant, to arrange an informal conference of masters and men. The result was a representative and reasonably-disposed gathering, at which the employers practically repeated the offers balloted on five weeks previously. An agreement was drawn up, which the delegates of the men present at the conference undertook to recommend the workmen in both the Clyde and Belfast districts to accept and abide by. The following is the substance of this important agreement:—

Firstly, the employers agree to give the following advances immediately on work being simultaneously resumed in the shops of the associated employers of the upper and lower districts of the Clyde and at Belfast, viz.:—(1) To the Belfast operatives one shilling per week; (2) to the Clyde operatives (*a*) an advance of one farthing per hour to all who, prior to the stoppage, were in receipt of less than sevenpence per hour, and (*b*) a further advance of one farthing per hour all round—that is to say, an advance of one halfpenny per hour to all under sevenpence and one farthing per hour to all who earned at and above that rate. Secondly, the rate of wages to remain in force undisturbed for a period of six months from December 11th, 1895, *i.e.*, until June 11th, 1896. After May 11th, if any change is demanded, one months' notice to determine the arrangement may be given, the arrangement continuing in force during said month. Thirdly, the word "operatives" shall include the following classes of tradesmen on the Clyde and at Belfast, viz.:—Fitters, finishers, turners, planers, borers and slotters, and shall also include, so far as Belfast is concerned, any patternmakers, smiths, and brass finishers who are members of the Amalgamated Society of Engineers.

The agreement was signed on behalf of the Federated Employers by R. Sinclair Scott, chairman of Joint Committee, and Thomas Biggart, secretary. On behalf of the Executive Council of the Amalgamated Society of Engineers it was signed by Alfred Sellicks, President E.C., and John Anderson, General Secretary. It was countersigned by Lord James of Hereford. A note was appended to the effect that, "although not made a formal term of this settlement, the employers and operatives, with the hope of restoring perfect good feeling, will do their best to replace the state of employment in the same condition as it was before the strike and lock-out occurred. Neither the employers nor operatives to be subjected to any exceptional treatment on account of what has occurred."

The terms of the agreement, on being balloted upon, were accepted by the Clyde men by a large majority, but the Belfast men by as great a proportion rejected them. The Central Executive of the men's society in London hereupon resorted to measures which, if they had been exercised a little earlier in the dispute, might have had a like result, much to the advantage of the workmen and the prosperity of the engineering and allied industries. They wired on the 21st inst. to the recalcitrant operatives at Belfast as follows:—"Call mass meeting of men for to-morrow, Wednesday. Member of Central Executive will be present. Strike must be settled at any cost." This, as might have been expected, caused dissatisfaction and some consternation in the rank and file of the workers, while the Belfast officials themselves, it is said, felt resentment at this unexpected application of the coercive principle. The executive, however, having the large majority of the members of the society on their side, and the unmistakeable support of the general public, as well as the potent lever of control of the society's purse-strings, the issue was inevitable. The men, and the local officials, after hearing the statements of Mr. McDowell, the executive's representative, gave a reluctant assent to the terms of the Carlisle agreement, and accentuated their reluctance by a "protest," and by declining to start work until Thursday.

The Belfast men have been idle fifteen weeks, and the Clyde men twelve. Into the lessons to be drawn from this memorable dispute it is not intended here to enter, but it may shortly be asked—What has been the result of the dispute of these three months' duration? An enormous amount of money has been lost to Belfast and Glasgow workmen, especially in the shape of wages, and one of the most important British industries has got a shock from which it may take some time to recover. It is calculated that since the strike on 6th November, the Clyde engineers have lost in wages something like £45,000. When the loss of the labourers and the other trades depending upon the engineering industry is taken into account, the sum must be enormous. Then, besides, there has been drawn from the funds of the Amalgamated Society of Engineers, for the support of the Clyde men alone, a sum roughly estimated at £20,000. Though the men of Belfast have got half their demand, and the men of the Clyde have got a good deal more than they at first asked for, it will be long before these increases make up for the amount dropped in wages during the period of cessation.

One feature connected with the general resumption of work, both at Belfast and on the Clyde, remaining to be noticed, is the refusal of the employers to reinstate unconditionally the apprentices, who, during the height of the contest, "joined their lot" with the men on strike. This refusal might have been anticipated by both apprentices and workmen from the nature of the latter's position as indentured servants, as well as from their having stopped work directly in face of the advice and warning of their employers. Nevertheless, the refusal to reinstate the apprentices in a body, and unconditionally, caused friction, and a disinclination at first to refuse to resume work on the part of sections of the men.

This, however, has rectified itself, and it has become recognised that the masters are quite entitled to deal with their rebellious young servants as they may deem essential to a proper understanding of their position and future conduct. Stipulations to that end have been drawn out, and each apprentice is being compelled to sign the document before reinstatement. While to a certain extent dealing with the lads on disciplinary lines, the stipulations are chiefly designed to make clear, to both apprentices and workmen, that in future trade disputes of this kind the apprentices must in no way try to make themselves, or be made, active factors in the solution of the questions at issue.

Apart from the hitch in connection with the reinstatement of the apprentices, the start in the engineering shops of the Clyde has been general, although little difficulties presented themselves in at once finding jobs for all who applied. In some of the shops arrears are so heavy that work will be carried on day and night for a considerable time to come. Simultaneously with the resumption of work announcements have been made of several good contracts for ships and engines, and important orders which have been booked during the period of the strike and lock-out have not yet been made generally public. Steel merchants are having a large inquiry for material, but few are disposed to commit themselves unless at better prices. The Steel Company of Scotland a few days ago raised the price of angles to £4 15s., an advance of 2s. 6d. a ton. The same company has been quoting £5 5s. for ship plates; some other makers have accepted 2s. 6d. less, but the quotation now is generally at the higher figure, and sellers firm there. The total tonnage booked since the first day of the year will be seen, by the end of this month, to amount to a pretty big figure, considering the all but complete absence of launches. Port Glasgow and Greenock firms have booked most heavily. Messrs. R. Duncan and Co. since mid-month have contracted to build two steamers, one of them of 2500 tons; Messrs. A. Rodger and Co. have arranged to build two steel screw steamers for traffic on the river Amazon, the engines for which will be supplied by a Govan firm; and Messrs. Russell and Co. have booked an order for a third vessel for Amazon passenger traffic. Messrs. Rankin and Blackmore, engineers, Greenock, have contracted to build a first-class twin-screw land and dipper dredger for the Lancashire, Yorkshire, and London and North-Western Railway Company's marine service. The hull is to be constructed by Messrs. Murdoch and Murray, Port Glasgow, while Messrs. Rankine and Blackmore will provide the engines on their patent disconnecting triple-expansion principle. Messrs. Fleming and Ferguson, Paisley, have contracted to build for the Cork Harbour Commissioners a steel self-propelling dredger of about 1000 tons capacity. The general feeling is, that now the unfortunate engineering trouble is over, better trade experiences are in store for the Clyde and West of Scotland.

THE SCHMIDT SUPERHEATED STEAM MOTOR AND BOILER.

ONE of the most noticeable improvements in small steam engines in the direction of economy of fuel is the motor introduced by Messrs. W. Schmidt and Co., of Aschersleben, in Prussian Saxony, driven by "hot," *i.e.*, highly superheated steam, which is represented in both engine and boiler presenting considerable departures in form from those of ordinary steam generators and motors.

The boiler in its original form, represented in Figs. 7 to 11, page 105, is of an ordinary upright kind, with internal furnace and three cross circulating tubes, with a central chimney surrounded by a series of serpentine coils for superheating. These coils are not in continuous connection, but are divided into two series, the first and second counting upwards forming the so-called fore superheater, and the remaining eight the after superheater. A communication between the two series is provided in the vertical cylinder on the left, called the after evaporator. The cylinder containing the coils is covered with a cast plate perforated with numerous small holes, and the central chimney by a movable damper. When the latter is open the fire gases pass directly through the central tube into the chimney, but when it is closed they are diverted through the small flues in the bottom of the superheater covering, and pass upward through the coils, their distribution being regulated by the holes in the covering plate.

The proportions of the boiler are such as to admit of very rapid production of proportionately wet steam, the evaporation according to the experimental trials being at the rate of 45 to 50 kilos. per square metre of heating surface per hour. The mixture of steam and water passes from the boiler by the valve l, though the coils of the lower superheater, which are exposed to the hottest of the fire gases, but are protected against burning owing to the heat absorbed in the evaporation of the entangled water. The final drying is done in the after evaporator by an interchange of heat between the remaining water and the partially superheated steam. That such an interchange does go on is apparent from the difference in temperature between the top and bottom of the after evaporator, which is about 50 deg. C. The dry steam enters the main superheater at the top, coming out below heated to or about 350 deg. C., or 180 deg. above its saturation temperature, and passes by the valve K to the engine supply pipe.

All the exposed surfaces of the boiler and superheaters are closely covered with non-conducting materials. The fire-box has a thick fire-brick lining, whereby a certain portion of the heating surface is lost, but with the advantage of forming a mud pocket in the lowest part of the boiler, which being comparatively cooled allows the mineral matters separated from the feed-water to settle down in loose form instead of compacting as a hard incrustation upon the plates. The engine, which is of 20 nominal horse-power, is, as will be apparent from our illustration—Figs. 1 to 6, page 000—similar in appearance to a gas engine, having two single-acting cylinders, with pistons of 220 mm. diameter and 375 mm. stroke coupled upon the same shaft at 180 deg., with the valves placed up the back of the cylinders. The valves are of the vertical piston form, the steam being admitted through the central passage O in the framing, and passing out through the lower one at p. They are moved by levers $h\ h$ on a weigh shaft k from the excentrics $i\ g$ and $g\ i$, the former, which is connected with the exhaust, moving in an invariable path; while the latter, which controls the admission, is subject to the action of a governor attached to the fly-wheel. The lubrication of the main shaft bearings and excentrics is effected by the two oil vessels carried on the tubular frame v; the overflow collects in a reservoir in the lower part of the framing.

An engine and boiler of this class constructed by Mr. J. E. Christoph, of Niesky, in Silesia, of somewhat larger dimensions than those in our illustrations, were subjected to a series of trials by Professor Lewicki of Dresden, in order to determine the following points:—(1) Steam consumption of the engine when fully loaded. (2) Frictional resistance of the unloaded engine. (3) Useful effect under different conditions of work. The engine has two cylinders of 250 mm. diameter and 400 mm. stroke. The heating surface of the boiler was 5·8 square metres. The principal results are tabulated as follows:—

Duration of trial	5 hr. 10 min.
Steam pressure in boiler, effective	8·81 atm.
Temperature of feed-water	17 deg. C.
Temperature of feed-water from feed-water heater	84·1 ,,
Pyrometer reading, bottom of fore superheater	596·1 ,,
Pyrometer reading, bottom of after superheater	412·9 ,,
Steam temperature in after evaporator, below	296·2 ,,
Steam temperature in after evaporator, above	287·8 ,,
Steam temperature, engine admission	345·7 ,,
Steam temperature, engine exhaust	143·3 ,,
Steam temperature, feed-water heater	101·1 ,,
Air temperature in engine-room	27·3 ,,
Feed-water per hour	331·19 kilogs.
Revolutions of engine per minute	157·93
Indicated horse-power	48·48
Effective horse-power	41·47
Steam consumption per I.H.P. per hour	6·83
Steam consumption per effective H.P. per hour	7·98
Coal	1·10 kilogs.

The friction of the unloaded engine when running at 159·46 revolutions per minute represented 2·12-horse power, and the difference in speed between the engine when light and when fully loaded was only 0·96 per cent.

The effective power under different conditions of steam admission and speed varied as follows:—

Stage.	Revolutions per minute.	Indicated horse-power.	Effective horse-power.	Efficiency, per cent.
1	160·55	15·35	11·09	72·2
2	158·55	26·95	21·99	81·3
3	157·55	38·65	32·66	84·5
4	157·93	48·48	41·47	85·5

An ordinary non-condensing steam engine would probably require for the same work 16·38 kilogs. of steam and 2·10 kilogs. of coal per horse-power hour effective, so that the saving by high superheating is 351·76 kilogs. of water and 41·47 kilogs. of coal on the power developed, or about 52 per cent.

A new form of construction of the Schmidt boiler by the Gritzner Engine-building Company of Durlach, in Baden, is shown on page 107, in which the superheating elements are placed behind the main boiler instead of above it, and a feed-water heater is added.

The boiler is on the ordinary single furnace tube Cornish pattern, has a heating surface of 15 square metres, and is intended to work at 12 atmospheres pressure. Provision is made for smokeless combustion by an accessory air-feed introduced through perforations in the firebrick bridge, such air being slightly warmed in its passage over the hot ashes below the grate. By means of a damper on the flue behind the furnace tube the gases may, when it is closed, be turned round the outside of the boiler in the ordinary way, but when open they pass into the bottom flue n and up through the superheater coils in the back chamber. These, as in the vertical form of the boiler, are divided into two series, a preliminary or drying set at the bottom, and a larger number above forming the superheater proper. The gases are deflected by the conical point at the bottom of the cone tube m, and distributed by the perforated plate m_1, as previously described.

The rectangular flue W leads the gases into the chamber containing the feed-water heater between the boiler and the superheater. This consists of a series of vertical cast iron pipes socketed into connecting mains above and below. At the top they are connected by the tubes g and g_2 with the feed admission of the boiler, a stop valve and three-way cock being placed between these latter pipes, so that the feed pumps may either send cold water directly into the boiler or draw from the heater. The final exit of the gases to the chimney is effected by two side flues, which are accessible by the covered manholes $x\ x_1$. The re-evaporator p is connected below with the drying coils, and above with those for superheating, as previously described. The superheated steam is conveyed to the engine by the pipe q. The remaining peculiarities of the design will be sufficiently apparent from the drawing, without special description.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Fleet engineer: Charles H. Pellow to the Penelope. Staff engineer: Stephen H. Blundell to the President, additional. Assistant-engineer: Gordon Robertson to the Vivid.

THE INSTITUTION OF CIVIL ENGINEERS.

RECENT DEVELOPMENTS IN GAS ENGINES.

AT the ordinary meeting on Tuesday, the 28th January, Sir Benjamin Baker, K.C.M.G., the President in the chair, the paper read was on "Recent Developments in Gas Engines," by Mr. Dugald Clerk, Assoc. M. Inst. C.E.

The author stated that the theory of the gas engine outlined in a paper read by him before the Institution in 1882 was now generally accepted, while the stratification theory had vanished. Great advances had since been made in gas engine construction, and the heat efficiency of such engines had been much improved, while their dimensions and power had increased. Engines working on the Otto cycle had been proved to be the best adapted of all yet invented for present needs, and their popularity had gradually led to the extinction of other types. The mechanical development of the Otto type was illustrated by the comparison of drawings of an engine built thirteen years ago with those of one recently constructed. The advance in heat efficiency was almost, if not completely, due to increase in the pressure of compression before explosion. It was shown that each step of diminished gas consumption of the Crossley Otto engine was attended by an increase in compression. The results were summarised in the following table, showing the absolute indicated efficiency of Crossley Otto engines of similar size since 1882:—

	Efficiency.	Pressure of compression above atmosphere. lbs. per sq. in.
1882-88	0·16	38·0
1888-94	0·19	66·6
1894	0·25	87·5

These results showed that economy increased with the compression, but it was open to question whether the increased compression completely accounted for the improved performance. To test this the author had calculated, by the formula $E = 1 - \left(\frac{c_c}{v}\right)^{\gamma - 1}$, the theoretical efficiency of an air engine in which no practical loss occurred, the air engine having the same ratio of compression space as the actual gas engine. These theoretical efficiencies, as well as the actual efficiencies obtained in the gas engine, were shown in a table, from which it appeared that the economy had improved, chiefly on account of the increased compression. It was noted that in every case the actual indicated efficiency obtained from the various gas engines was about one-half that which would have been given by an ideal air engine following the same cycle in a perfect manner without loss to the sides of the cylinder. Also that the actual efficiency improved more rapidly with the increase of compression than did the thermodynamic advantage due to the compression. Thus, when the theoretical efficiency was 0·33, the actual experimental efficiency was $0·33 \times 0·45 = 0·15$; and with the theoretical efficiency 0·39, the actual efficiency was $0·39 \times 0·48 = 0·19$; while with 0·428 theoretical efficiency, the actual efficiency was $0·428 \times 0·58 = 0·25$. The ratio of actual to ideal efficiency thus rose with increase of compression from 0·45 to 0·58, and this, it was stated, meant that with higher compressions two advantages were obtained, the thermodynamic advantage, due to improvement in cycle, and a further advantage due to diminution of the proportional loss of heat to the cylinder walls.

In comparing the earlier with the recent Crossley Otto gas engine, it was pointed out that the great differences between the two engines, which resulted in the superior economy of the later, were found in (*a*) the abandonment of the flame slide-valve ignition, and the substitution for it of ignition by an incandescent tube of metal or other material; (*b*) the diminution in the relative volume of the compression space; (*c*) the improved proportioning of the valves and ports in order to minimise the throttling of the charges during the inlet period, and the back pressure of the exhaust gases during discharge. This statement was illustrated by reference to numerous indicator diagrams. The author described his tests of the new Crossley Otto scavenging engine, stating that although it was highly desirable to discharge all the exhaust gases and replace them by pure air, as so long contended by him, yet that such displacement was not accountable for more than 5 per cent. of the improvement produced in the Otto scavenging engine. It was stated that scavenging possessed practical advantages quite apart from improvement in gas consumption. Otto gas engines, constructed by Messrs. Andrew and Co., of Reddish, and by Messrs. T. B. Barker and Co., of Birmingham, were also described and illustrated, and the various peculiarities of the different Otto-cycle engines were pointed out. It was stated in discussing these engines that engineers had not sufficiently recognised the importance of limiting the port-surface to the utmost, in order to minimise the cooling surface in contact with the intensely hot gases. The Barker engine was referred to as one in which this point had been kept well in mind by the designer. Various self-starting gears were described, more particularly the Clerk pressure starter, the Clerk-Lanchester starter and the Lanchester low-pressure starter.

From a mechanical point of view the Otto cycle was a very imperfect one, allowing at most an impulse for every two revolutions of the crank shaft for each single-acting power cylinder; but the mechanical imperfections of the engine had until now been more than compensated by the simplicity of the single cylinder and piston, and the readiness with which the practical conditions of charging, exploding, expanding, and exhausting could be made to comply with the requirements of economical working. The great difficulty of the problems involved in impulse-every-revolution gas engines was then referred to, and the author described several engines which had been designed with a view to overcome those difficulties. In the first engine built by the author, early in 1878, there were two cylinders, each having a diameter of 6in., with a length of stroke of 8in., one a pump cylinder, and the other a motor cylinder. The pump crank followed the motor crank at right angles, and it pumped the mixture of gas and air into an intermediate reservoir through a check valve. From this reservoir the explosive mixture was supplied to the motor cylinder by means of a slide valve, and was compressed in the reservoir to a pressure of 70 lb. per square inch above the atmosphere. The motor piston moved back to the end of the cylinder, leaving only a mechanical clearance, and the exhaust valve was shut a little early in order to cushion the piston, as was done with steam engines. The motor piston moved forward from the end of its stroke about 2in., taking in the compressed mixture from the reservoir: the slide valve then cut off the supply, and ignition was effected by an incandescent platinum cage carried in the slide. The engine had been exhibited at the Royal Agricultural Society's Show at Kilburn in 1879, and was, the author believed, the first compression gas engine working by explosion ever built which gave an impulse for each revolution of the crank shaft. The difficulties which prevented the success of this type of engine were described. The author's 1881, 1886, and 1889 engines, as well as the "Differential" engine and the "Cycle" engine of Mr. Atkinson, were similarly dealt with.

The author then considered the modifications still to be made in the indicator diagram of a gas engine to further increase its heat efficiency, and in this he particularly referred to the Otto cycle, although he stated that it was to be remembered that impulse-every-revolution engines could now be arranged to produce any of the results brought about by the Otto engine. It was pointed out that the actual indicated efficiency of a gas engine increased with the theoretical efficiency, and that the actual efficiency varied between 0·45 and 0·58 of the theoretical efficiency. It was also stated that the indicated efficiency increased with the dimensions of the engine, other things being similar, when the ratio of compression space—and therefore the theoretical efficiency—remained constant. Thus an engine having a cylinder 9½in. in diameter with a length of stroke of 18in. had a theoretical efficiency of 0·40, and gave an indicated efficiency of 0·19 or 0·47 of that theoretically attainable. An engine, having a cylinder 14in. in diameter with a length of stroke of 25in., of which the theoretical efficiency was 0·41, gave an actual efficiency of 0·277, that was 0·675 of the theoretical efficiency. The actual efficiency, instead of being only 0·47 of the theoretical, increased to 0·675 without practical change in the compression. This comparison proved that efficiency increased with the dimensions. It was pointed out that a limit was reached to the increase of efficiency due to increase of dimensions, and the conditions were calculated. It was shown that further economy might be obtained by increasing the compression and expansion, but it was considered that for high compressions and large gas engines it would be advisable to adopt the compound principle, although the conditions of success, for compound gas engines, were not yet fully understood.

In conclusion, the author considered that the gas engine would yet assuredly be applied upon railways and to ships, just as it was now used in factories; its principles were better understood, and engineers were daily improving their knowledge of the properties of flame, and the means of harnessing flame instead of steam.

MOTOR CARRIAGE NOTES.

A NOVEL case came before Police Judge Mitchell at the Central Police Court, Glasgow, on Wednesday, the 22nd inst. George Johnston, Mosesfield House, Springburn, was charged with having contravened the Locomotives Amendment Act, 1878, Sec. 6, in so far as he, being in charge of a locomotive propelled by steam, oil, or other than animal power, and designated a horseless carriage, did, on January 4th, 1896, between 4 and 5 p.m., drive the locomotive along Buchanan-street, St. Enoch-square, and Dixon-street, being highways along which locomotives are prohibited to pass between 9 a.m. and 5 p.m., whereby he was liable to a penalty of £5, or one month's imprisonment. He pleaded not guilty.

David Menzies, portioner, 7, Buckingham-terrace, stated, in reply to the Procurator-Fiscal, that he was the companion of the accused on the carriage on the day libelled. He would describe it as a phaeton, not as a locomotive. There was no appearance of mechanical power outside.

By Mr. Johnston—Going at the rate of from four to eight miles an hour it would stop within one and a-half yards. On their way from Springburn to Paisley they passed about 200 horses, and only two of them noticed it. None of the tramway horses shied. It was much easier handled than an ordinary spirited horse. It could be turned in a shorter distance than an ordinary vehicle. It did not make so much noise as a cab. There was no discharge from it. There was no boiler or furnace.

Mr. Johnston said it was more or less an experimental carriage. He would be very glad if the magistrate examined it.

Constable Melvin said he was stationed at the junction of Argyll-street and St. Enoch-square. About 4.20 on the day libelled accused was driving a horseless carriage. The machinery seemed to be set in motion by the foot. There was a little vapour came out below the carriage. There was no discharge of oil on the ground.

By Mr. Johnston: The machine sometimes made a slight noise. It made more noise than an ordinary cab. It drew up very quickly. The carriage passed close in front of the horses of a tramway car, but they were not startled. He had seen the carriage pass before, but had never seen a horse startled by it.

For the defence,

David Simpson, 23, Saracen-street, said he was an engineer in the employ of the accused. He had been working at horseless carriages for several months. This was an ordinary vehicle without shafts. It had four wheels, and was seated for three persons. There was no appearance of machinery. It was impossible for vapour to come from the carriage unless as a result of gross carelessness or of an accident. There was no boiler or furnace. The driver only required to touch the brake with his foot, and then the machinery stopped working, and the brake was applied. It was a strap brake, as on a train.

By the Assessor (Mr. Young): The carriage was propelled by machinery, by an oil motor. There might be a discharge of a little vapour on a long journey. It was impossible to see the products of combustion.

Norman Fulton, engineer, Mount Vernon, gave similar evidence. In reply to the Fiscal, he defined a locomotive as essentially an engine used for traction purposes. In this case the essential part of the vehicle was the carriage.

The Fiscal said that Mr. Lang had advised the magistrates that the definition of a locomotive applied to every locomotive propelled by steam or other than animal power.

Mr. Johnston quoted from various dictionaries in favour of his contention that this carriage was not a locomotive within the meaning of the Act. He had been compelled to take out an Excise licence, which authorised him to run a carriage propelled by not more than two horses or mules, or by mechanical power. No licence was required for a locomotive. At the time this Act was passed it was impossible for the Legislature to have had in contemplation a vehicle of this description. The motor only weighed 1¼ cwt. out of the 10 cwt. which the carriage weighed.

The magistrate continued the case for judgment till the 24th, when a nominal penalty of 2s. 6d. was imposed, as it was the first case of the kind.

THE award of prizes for the motor carriages which took part in the recent competition at Chicago has been announced, and is given below. All the carriages have been illustrated and described in THE ENGINEER of November 22nd, 1895, and January 3rd, 1896. (1) Morris and Salom, electric carriage.—Gold medal awarded for the best showing made in the official tests; for safety, ease of control, absence of noise, vibration, heat or odour, cleanliness, and general excellence of design and workmanship. (2) Duryea Motor Wagon Company, gasoline carriage.—An award of £400 for the best performance in the road race, and for range of speed and pull, with compactness of design. (3) H. Mueller and Co., gasoline carriage.—An award of £300 for performance in the road race, and for economy in operation. (4) R. H. Maey and Co., gasoline carriage.—An award of £100 for the performance in the road race. (5) Sturges Electric Moto-cycle Company, electric carriage.—An award of £100 for the performance in the road race.

The following special awards were made by the committee on tests for meritorious features in design:—(6) G. W. Lewis.—An award of £40 for friction driving device and brake, and a reduction gear for increasing the speed. (7) Haynes and Apperson.—An award of £30 for the plan of preventing vibration by the balance of the driving engines. (8) Max Hertel.—An award of £20 for a device for starting the motor from the operator's seat in the carriage. (9) De La Vergne Refrigerating Machine Co.—An award of £10 for the counterbalance on the engine.

The American Motor League has been organised as an outcome of this competition, and will be devoted to the interest of the horseless carriage or motor carriage, by encouraging the improvement of the motors, the carriages, and the public roads. Its objects are to hold meetings for the presentation and discussion of papers and reports, to direct favourable legislation, to defend the rights of motor carriages on the public roads, to aid in the mechanical improvement of the machinery, and to aid also in the existing movements for securing good roads. Mr. Charles E. Duryea, of the Duryea Motor Wagon Company, is president, and Mr. J. Allan Hornsby is secretary.

AT the Tunbridge Police-court, Mr. Walter Arnold, the owner of a motor carriage, was summoned on four informations with reference to using a motor carriage on the highway. The first was for using a locomotive without a horse from the County Council, the second for having less than three persons in charge of the same, the third for going at a greater rate than two miles an hour, and the fourth for not having his name and address placed on the machine. The evidence was that the carriage was going at the rate of eight miles an hour. Mr. Cripps, who defended, contended that the machine was not one contemplated when the Locomotive Acts were passed, and said that in the past these carriages had been used by Sir David Salomons and the Hon. Evelyn Ellis without any notice being taken. If the Bench considered that the carriage was a locomotive, he asked for the imposition of a nominal penalty. The Bench inflicted a penalty of 5s. and £2 0s. 11d. costs for using the carriage without a horse, and 1s. and 9s. costs in each of the other three cases—£4 7s. altogether.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

THE following circular is now being issued by the Council of the Institution:—

28, Victoria-street, Westminster, January, 1896.

The Council of the Institution of Electrical Engineers have resolved, "That steps should be taken to render available for purposes of national defence the technical skill of electrical engineers, and that a committee be appointed with instructions to take such steps as it thinks fit to attain that end," and have appointed the following gentlemen as members of the committee:—The President—Dr. J. Hopkinson, M.A., F.R.S.—Sir Frederick Abel, Bart., K.C.B., D.C.L., F.R.S., Mr. R. E. Crompton, and Major-General C. E. Webber, C.B.—Past Presidents—Mr. H. Edmunds, Mr. R. S. Erskine, and Mr. A. E. Mavor, to whom have since been added Sir Benjamin Baker, K.C.M.G., LL.D., F.R.S., and Professor A. B. W. Kennedy, LL.D., F.R.S.

It hardly seems necessary to point out in how many ways a practical knowledge of electrical science could be made useful in time of war. Everyone knows that the acquiring of a knowledge of this science is a not unimportant part of the training of military engineers. This knowledge electrical engineers already possess, but they have at present no opportunity in time of peace of preparing for the practical application of that knowledge for the purposes of war.

In order to carry out their instructions, it is necessary for this committee to ascertain what support it may expect from members of the Institution, and others engaged in electrical industries. Hence the present communication and the following questions are addressed to you:—

(1) Are you willing as an electrical engineer to register your name as ready to undergo training, and to serve in case of urgent need? (2) Are you willing to begin training at an early date, and to accept a commission in the Reserve Forces if obtainable, or to join the ranks of a Volunteer Corps? (3) Which branch of the Reserve Forces do you prefer? (4) Would you prefer to join a special corps of electrical engineers?—(*a*) as an officer; (*b*) in the ranks. (5) Are you at present a member of any Volunteer Corps?

One of the objects of this committee is to ascertain if there are candidates amongst the electrical engineers to fill the vacancies in the list of officers.

In order to enable you to judge of the matter, it may be well shortly to state the existing conditions of service in the various corps, particularly of military engineers, which now form part of the Reserve Forces of this country.

These are divided between Militia and Volunteers, and are described, with a list of the names of the commissioned officers, in the monthly "Army List," which also gives the various places where those corps are located.

With one exception—the Corps of Railway Managers and Engineers—they are formed in battalions and companies, having the usual military organisation.

The Volunteer Force is composed of the following arms:—Light Horse, Artillery, Engineers—Fortress and Submarine Mining, Rifles, and Medical Staff Corps.

The Corps of Engineers—Submarine Mining—is perhaps the arm to which electrical knowledge is most extensively applied at the present time. There exist divisions located on the Clyde, Forth, Mersey, Severn, Tay, Tees, and Tyne. The divisions are in general highly efficient, but there is a lack of officers. The preliminary training of officers requires in all about six weeks' work, which may be spread over two years. The duties of officers include attendance in camp at the headquarters of their division for not less than eight or more than fifteen days, and at forty-eight drills, a full day's work counting as six drills. The advantages are very interesting and healthful work, and an allowance of 10s. a day employed in training or in camp.

In the other arms there is much less need for attendance at a camp which may be remote from the home of the volunteer. The corps of Fortress Engineers is recommended to those who cannot afford time for prolonged attendance at a distance from their residence. The following is a list of the existing regiments of Fortress Engineers:—1st Middlesex, 1st Lanarkshire, Edinburgh City, 1st Lancashire, 1st Newcastle-on-Tyne, Yorkshire (West Riding), 1st (Sheffield), 2nd (Leeds), Gloucestershire 1st (Cheltenham), Cheshire 1st (Birkenhead), 2nd (Railway) Crewe, Denbigh, Tower Hamlets 2nd (East London), Cumberland, Surrey, Hampshire 1st (Portsmouth), Glamorgan, Essex, Devonshire and Somerset 1st (Exeter), London 1st (North), Flintshire 1st (Buckley), Northamptonshire 1st (Peterborough), Durham 1st (Jarrow), Aberdeenshire 1st.

In the case of the Militia, longer attendance is required in camp than in the case of the Volunteers; for example, the Militia Submarine Miners have annually fifty-five days in camp, and during the first year four months' training. Of this arm there are divisions located at Portsmouth, the Needles, Plymouth, the Thames, the Medway, Harwich, Milford Haven, Western—Severn—the Humber, and Falmouth.

Special corps.—The modern development of the uses of electricity is certain to lead to its extended application in war time. It is proposed, therefore, subject to the approval of the War-office, to organise and train a special corps of electrical engineers, whose duties will be defined at a later date.

It will further be the object of the committee to ascertain if the military authorities will regard favourably the enrolment of electrical engineers on some such basis as was followed in the case of the railway engineers, by which the services of many who cannot afford the time for organised training, but who are willing to seek certificates of efficiency suitable to their attainments, can be promptly utilised by the War-office in case of national emergency.

This statement will, we believe, enable you to judge which branch of the force you could most usefully join. Will you kindly reply to the questions put on the accompanying form? Later, if you are disposed to take an active part in the movement, you may expect to hear from us further.

If you occupy a leading position, superintending the work of artisans, will you also ascertain and inform the committee how many of these in your employment would be willing to join such a special corps as has been suggested.—On behalf of the committee,

J. HOPKINSON, President.

IT is stated that an estate, known as the Hafslund, near the great waterfall called the Sarpsfos, between there and Göteborg, has been acquired by a syndicate, consisting chiefly of German and American capitalists, for the sum of 800,000 kroner. The purchasers intend to form a large company with a capital of three to five million kroner, in order to utilise the water power of the falls for electrical power, and establishing aluminium works on the same principle as planned at the Falls of Foyers in Scotland. The Sarpsfos is one of the finest falls in south-eastern Norway being 74ft. in height and 116ft. in width.

RAILWAY MATTERS.

A Chicago paper reports the number of persons killed on railroad tracks—other than street surface roads—in that city during the year 1895 as 274, including seven passenger, 55 employés, and 212 other persons. There were six suicides. A list is given showing the number killed on each road in each month. The coroner gives the number of cases on each road in which the company was censured by the jury. The largest on any one road is six, and the total is 49, or about one case out of six. There were 62 fatal accidents on the street railroads.

The first number of the tenth volume of the "Bulletin of the International Railway Congress," English edition, edited by Mr. W. M. Acworth, and published by M. Weissenbruch, Brussels, contains, amongst other things, a paper on "Economical Methods for Increasing the Delivery of Water Cranes Without Having Recourse to the Use of Reservoir Cranes or Water Towers," by Sig. C. Coda, of the Italian Mediterranean Railway. It also contains a paper on "Lubrication of the Vehicles on the Eastern Railway of France," by M. Saloman, the chief mechanical engineer of the line.

A presentation was made in the "Hamilton Room" of the Great Eastern Hotel, Liverpool-street, E.C., on the 22nd inst., to Mr. Charles Langbridge Morgan, M. Inst. C.E., on his retiring from the Great Eastern Railway to take up the appointment of Engineer-in-Chief to the London, Brighton, and South Coast Railway. The presentation was made on behalf of the subscribers by Mr. John Wilson, M. Inst. C.E., Engineer-in-Chief to the Great Eastern Railway, and consisted of a very handsome silver tea and coffee service and salver, together with an album containing an illuminated inscription on vellum, and the names of the subscribers.

The tunnel of the underground electric railway connecting Waterloo Station with the City is making rapid strides towards completion, for there remains to be made now only about 1500 yards near the terminal stations. As during the past six months a total length of 1635 yards was driven, it is confidently estimated that the work of tunnelling will be finished before Midsummer Day. At present the tunnel citywards has reached a point about midway between Benet's Hill and Lambeth Hill, near the College of Arms. At the Waterloo end the tunnel has been driven about 150 yards eastward of the junction of the Waterloo Bridge-road with Stamford-street.

The Board of Works of the city of Newark, N. J., has passed an ordinance prohibiting the street railroads of that city from carrying freight or doing an express business. The electric railroad companies have, however, according to the *Railroad Gazette*, made extensive plans looking to the transportation of freight, and it is said that the Consolidated Traction Company already has a number of freight and express cars. An officer of one of the street lines has published a letter warning the city that in prohibiting the transportation of freight on street car tracks it is injuring its own interests, as several manufacturers now looking for sites for factories will come to Newark, if they can have track connections, and will stay away if they cannot.

At the recent meeting of the committee of the Light Railways Association of Great Britain, the committee discussed the report of the Board of Trade Committee and afterwards considered the Light Railways Bill of the late Government. Clauses were added for the purpose of regulating the charges upon light railways, for enabling tenants for life to exercise their powers as to improvements under Lord Cairn's Act, and for conferring permissive powers enabling local authorities to assist such undertakings by funds or guarantees. Powers were also inserted giving to local authorities the right to purchase the railways after a certain time, in cases where such pecuniary assistance had been rendered. A clause was also agreed to providing that no deposit should be required until lines had been authorised. A sub-committee was appointed to draw up a report to be presented to the President of the Board of Trade by the deputation.

A Board of Trade report on the collision which occurred on the night of November 25th last at Wortley South Junction on the Great Northern Railway has been published. As a Lancashire and Yorkshire Company's train from Leeds to Wakefield was passing the signal-box at the junction it ran into a Great Northern light engine, which was standing on the Great Northern up main line. Thirty-five passengers were reported to have complained of injuries, but in no case were the injuries serious. The driver and fireman of the train engine were also rather badly hurt, but the men on the light engine jumped off just before the collision took place and escaped. The inspector finds that the accident was due to a mistake on the part of signalman George Reed in the Wortley south signal-box. Reed, under the impression that the light engine was in the West Yorkshire siding, accepted the Lancashire and Yorkshire train from Leeds on the up main line, and lowered all the signals for it. The Government inspector is satisfied, however, that the signalman acted in good faith, but he says that the misunderstanding which led to the collision would not have occurred had there been less shouting. and if each of the three officials concerned had been at a little more pains to explain his intentions.

The officers of the New York and Brooklyn Bridge have tried the experiment of communicating by telephone between the Train Dispatcher's-office and the motormen on the cable cars running across the bridge, and it is reported that such a telephone connection will be made a permanent thing. Electrical communication with the moving cars was made by means of the overhead wire strung along the tracks, which at night is used for conveying a lighting current to the cars. It would seem to be at least doubtful, however, whether this will be a successful expedient for preventing such collisions as that of November 19th. That collision was between trains which normally run only a minute or a minute and a-half apart, and in the absence of automatic block signals placed very close together—say at intervals of 500ft.—and worked on the absolute plan, it is difficult to see how there is any better way of running on time during dense fogs than by employing men to signal by flag, lamp, or torpedo. To communicate from one car to another through a central office, by word of mouth, besides being clumsy, would demand almost impossible vigilance on the part of the dispatcher. There would be frequent occasions when a signal ought to be conveyed in a good deal less than fourteen seconds, as claimed for the telephone arrangements.

In a short paper on locomotive service read by Mr. J. H. McConnell before the Western Railway Club, U.S.A., writes against the temptation to the motive power official to subordinate the freight train load to the fuel and repair account of his locomotives. The *Railroad Gazette*, referring to this, says:—"A freight locomotive should be made to haul every ton of freight it is capable of hauling regardless of cost for repairs and fuel. It is perhaps this one thing which more than any other has enabled the railways of the United States to give the extraordinarily low freight rates, compared with those of foreign countries, which the American shipper enjoys. To subordinate the coal and repairs expense to the heavy train load has come to be the distinguishing principle of railway operations peculiar to American railway practice. While there is little danger that American railway managers will go back on this principle, there is always a danger that the mechanical department, particularly if it does not keep in close relation with the operating department, will gradually lose sight of it and devote its attention to increasing the locomotive mileage and reducing fuel expenses until low repair and fuel accounts come to be regarded as the great goal of its efforts. Mr. McConnell as a motive power official has done a good thing in calling the attention of those in charge of railway machinery to the fallacy of such ideas, and in showing from his own experience how the results he urges can be attained."

NOTES AND MEMORANDA.

At the last meeting of the Physical Society Mr. Campbell Swinton exhibited some photographs which he had taken by Professor Röntgen's method. These included several of metal objects inside wooden and cardboard boxes, and a very clear and sharp photograph of the bones of the hand.

As a single chemical individual of high illuminating power now easily obtained in a state of purity, acetylene offers obvious advantages as a secondary photometric standard. A flat flame of acetylene burning under a pressure of 30 cm. of water, and used with a screen, gave perfectly satisfactory results.

The average daily supply of water delivered from the Thames to London consumers during November was 113,148,287 gallons; from the Lea, 54,938,740 gallons; from springs and wells, 28,161,066 gallons; from ponds at Hampstead and Highgate, 153,199 gallons. The last is used for non-domestic purposes only. The daily total was, therefore, 196,401,292 gallons for a population estimated at 5,550,012, representing a daily consumption per head of 35·39 gallons for all purposes.

At a recent meeting of the Paris Academy of Sciences a paper was read "On the Calendar," by M. Flamant. A criticism of an alteration of the Gregorian rule for finding leap-year, suggested by M. Auric. The alternative proposed by the author, not to consider as leap-years the dates $(32)^n \times 100$, that is, 3200, 6400, &c., has the advantage of postponing any departure from the Gregorian rule for 1200 years. The length of the mean solar year deduced from this is only two-millionths of a mean solar day in excess of the truth.

The relative proportions of the supplies of water to London from the various sources were as follows, during last November:—From the Thames, 57·61 per cent; from the Lea, 27·97 per cent.; from springs and wells, 14·34 per cent.; from ponds, 0·08 per cent. for street watering. If the sea water scheme is realised, this will enormously reduce the draught on the Thames, and make the proposed pipe line from Wales to London unnecessary. London must not be made dependent on a pipe for its supply.

The annual report of the Superintendent of Public Works, State of New York, says:—"The whole number of tons carried upon the canals of this State during the season of 1895 was 3,500,314 tons, of which 2,327,481 tons was in transit towards tidewater and 1,172,835 tons was moved westward. Of these amounts 1,762,663 tons were through freight and 1,797,651 tons were way freight. The amounts carried by the several canals were as follows: Erie Canal, 2,356,084 tons; Champlain Canal, 966,335 tons; Oswego Canal, 64,691 tons; Black River Canal, 64,154 tons; Cayuga and Seneca Canal, 49,050 tons; total, 3,500,314 tons."

The *Gorno-Sawodsky Listok* states that, in the Sabutschine region of the Transcaucasus, a naphtha well lately bored to the depth of 140 saschen—160½ fathoms—in the Ararat concession, throws out daily as much as 50,000 pud—820 tons—of naphtha; and that another well was bored at Bibi-Eibat, in the territory of the Black and Caspian Sea Association, which during fourteen hours poured forth 800,000 pud—13,120 tons—of naphtha, and in a period of six days yielded, though not regularly, nearly 2,000,000 pud—32,800 tons. Owing to an obstruction, however, which had formed in the borehole, which is 10in. in diameter and 189 saschen—220½ fathoms—deep, the spring ceased flowing on 19th April, but again gushed out on 1st May, since which period it has yielded daily 200,000 pud—3280 tons—of pure naphtha.

An interesting article on "The History of the Introduction of the First Hermetically-sealed Thermometer into France," was published in a recent number of the *Cosmos*, with extracts from the correspondence of Pierre des Noyers, secretary to the Queen of Poland. In 1657 he sent a description of a Florentine thermometer to M. Boulliau, of Paris, with a drawing of it, which is reproduced in *Cosmos*, and in 1658 a specimen of the instrument was sent to Paris, and was apparently used by M. Boulliau on June 25th of that year. This thermometer was graduated by means of small black enamelled knobs on the outside of the tube, and was subsequently improved by the Accademia del Cimento. A full description, *Nature* says, of the instrument is contained in Professor Hellmann's "Anfänge der Meteorologischen Beobachtungen und Instrumente," in *Himmel und Erde*, vol. ii., page 175—see *Nature*, vol. xlii, page 207.

Referring to some lecture experiments on the nodes of a bell described in *Nature* by Mr. Osborn, Mr. R. L. Taylor, Manchester, writes:—"For some years I have been in the habit of showing these nodes in the following way. An ordinary glass bell-jar, 8in. or 10in. high, with a moderately broad, flat, ground edge, is held with the edge upright, and fine sand scattered all over the flat edge. It is comparatively easy to excite the edge with a bow in such a way that the sand will be driven off everywhere except at the four nodes. I have never been able, however, to obtain more than four nodes in this way. I have also employed a similar method for showing the nodes of a tuning-fork. If the fork is a moderately large one, it is held horizontally in the hand, and the upper prong is covered with sand. By bowing sharply near the middle and near the root of the prongs, two overtones can usually be obtained, the nodes of which are clearly marked by the sand."

The largest specimen yet found of natural crystallised carbon, a variety of the black diamond, such as is used for the crowns in diamond boring, was lately brought to the notice of the Paris Academy of Science, by M. Henry Moissan. This carbon, which weighs 630 grammes—3075 carats—was found in the province of Bahia, Brazil, between the Rio de Rancadcor and the Bicas stream, in the Lençoes territory. It is of rounded form and decidedly black, while its surface is partly smooth and partly wrinkled, the latter, when examined by a magnifying glass or microscope of small power, presenting the appearance of a substance which has given out gas while still in a pasty condition. The external aspect greatly resembles that of the minute grains of carbon obtained by M. Moissan in the buttons of iron and silver compressed by sudden cooling in water, while the colour is also identical. This large specimen is porous, having lost about 19 grammes since it was discovered in July last.

Professor Agassiz, in the *American Journal of Science* for December, gives some results of a series of tests which he has been making of rock temperatures at great depths in the Calumet and Hecla mines. The greatest depth so far obtained there is 4712ft., and the temperature has been taken at 105ft.; 655ft., or the depth of the level of Lake Superior; at 1257ft., or the level of the sea; at 1663ft., a depth equal to that of the deepest part of Lake Superior, and at four additional stations, each respectively 500ft., 550ft., 561ft. and 1256ft. below the preceding one. The deepest point at which temperatures have been taken was 4580ft. It is proposed to take a last reading, when the final depth of 4900ft. is reached, and at that time the details of the observations will be published in full. In the meantime, some of the results obtained are interesting. The highest rock temperature obtained at the depth of 4580ft. was only 79 deg.; that at 105ft. was 59 deg., which makes the average increase 1 deg. of temperature 223ft. Lord Kelvin had found this to be 51ft. for a change of 1 deg. of temperature, and the observations in the St. Gothard tunnel gave results of 60ft. for a similar change. Calculations based upon the latter observations make the crust of the earth approximately 20 and 26 miles thick. Professor Agassiz's observations make the crust over 80 miles thick, and give a temperature at a depth of 19 miles of only 470 deg., the older ratios showing for this depth 2000 deg. Perhaps these results would indicate different thicknesses of the earth's crust at different points on the earth's surface.

MISCELLANEA.

Messrs. John Fowler and Co. (Leeds), Limited, have asked us to announce that they are issuing £200,000 of Four per Cent. First Mortgage Debentures. For further particulars see our advertisement columns.

A Sheffield steel manufacturer, who has spent some months in the Transvaal, found in Johannesburg alone no fewer than thirty-two representatives of steel houses—English and Scotch—competing for orders in the Golden City.

In giving an account of the inventions of Alfred Ely Beach, its late editor, the *Scientific American* publishes an engraving of a typewriter, showing its mechanism, as made in 1856, and awarded a gold medal by the American Institute. His pneumatic postal receiving and despatch system is also illustrated and described.

Prizes having been offered for the best designs for a steel bridge over the Medway, at Snodland, Kent, that of Mr. H. Woodhouse, Liverpool, has been accepted. The bridge is 4380ft. long over all, of which 2880ft. is carried by steel arches, The centre span, over the Medway, is 240ft., and 75ft. high above T.H.W. to underside of bottom boom.

A quadricycle, fitted with a rotary pump and with fire hose, is described and illustrated in *La vie Scientifique*, as ready for the road and ready for pumping. In the latter case the rear wheels are raised above the ground and the pump put into gear, and the four men then work the pedals as though for propulsion on the road. It makes a very handy little fire engine.

The Board of Naval Bureau Chiefs has decided to furnish Gunboat No. 10, to be built by Lewis Nixon, at Elizabeth, N.J., with water-tube boilers. This will be the first vessel of the United States Navy to be completely supplied with such boilers, although the Monterey has one-half her boilers of this type. The Chicago will also be supplied with them for one-half of her battery. The other half will be Scotch boilers.

The death is announced of Mr. Abraham Davy, of the Oaks, Pitsmoor, Sheffield. Mr. Davy was the eldest son of the late Mr. Joseph Davy, one of the founders of the firm of Messrs. Davy Brothers, Park Ironworks, Sheffield, and was actively associated with its management from boyhood until his retirement a few years ago. He was also interested in the coal trade, and a director both of the Whitwood and the Eckington Collieries.

We understand that Mr. William O'Brien, who has been in the employ of the Fairfield Shipbuilding and Engineering Company since 1868, has just now severed his connection with that firm. During this period he held the position of outside manager for the last sixteen years, and successfully engined, amongst others of our noted greyhounds, the Arizona, Alaska, and Oregon, for the Guion Line; Umbria, Etruria, Campania, and Lucania, for the Cunard Company; and s.y. Livadia and Peter the Great.

A plate representing 415 tons of 8in. turret and barbette armour for the battleship Iowa and the armoured cruiser Brooklyn was tested at the Indian Head Proving Grounds on January 8th, with results unsatisfactory to the manufacturers, the Carnegie Steel Company. Two ports were cut in the plate to make it represent as nearly as possible the port-plate of a turret. A 6in. armour-piercing projectile of the Wheeler type, weighing 100 lb., was fired at the plate with a velocity of 1700ft. a second. The plate broke into three pieces. A second shot was fired at one of the pieces, which also failed to meet requirements.

President Cleveland's Message to Congress has had rather an adverse effect on the cutlery trade done by this country with the States. At the end of the last quarter of 1895 business had crept up to a satisfactory figure. In fact, the total trade done during that period had only once been reached since 1880, and that was during the year 1881. The first few weeks of this year, however, have seen a large falling off in the demand from the States. One of our leading establishments, mainly engaged on the American trade, have put their men upon short time. A similar remark applies to another large house who do a large business with the United States.

The five new 20-knot third-class cruisers, which are to be built for the Royal Navy by contract, will differ, the *Central News* learns, but slightly from the Petorius, which was designed by Sir W. H. White, K.C.B., Director of Naval Construction, in the early part of last year. Provision for the building of the new vessels will be made in the Navy Estimates for 1896-97, and the drawings for the new vessels are being prepared with all possible despatch, in order that their keels may be laid as soon as practicable. The cruisers will be equipped with eight 25-pounder and eight 3-pounder quick-firing guns, and two 16in. torpedo tubes, and will probably be ready for the pennant in the spring of 1897.

The work of making the surveys for the Erie New York State Canal improvements was begun on January 13th. The plan is to divide the canal into eleven sections, with an assistant engineer in charge of each section. Each engineer will have a force of ten to twelve men, not including three or four labourers. Mr. J. L. Little, Division Engineer, is quoted by the daily papers as follows:—"The first work on the improvement of the canals under the new law will probably be done in Buffalo. Buffalo is a feeder for sixty miles of canal, and it is necessary to get water there before anywhere else. The depth of water there is the keynote for the whole canal system. The scheme of the State engineer is to first start at Buffalo, and deepen the channel in the canal about 3ft. to Tonawanda Creek."

Railway material firms in the Birmingham district receive with satisfaction this week the intelligence that the result of a survey made by Mr. Grieve Macrone, C.E., to establish the practicability of a line of railway from the upper to the lower Shiré in Africa has proved to be even more satisfactory than was hoped for. Mr. Macrone was, it is understood, commissioned by a syndicate connected with the African Lakes Company, the most powerful trading corporation in British Central Africa; and it is now proposed to form a separate company for constructing a line between Chimoro and Blantyre. Chimoro is the highest point on the Shiré River to which steamers can ascend at all times of the year, and it is obviously desirable, therefore, that the railway should start at this place. A rival scheme has, however, been set on foot for building a line to Maperera and Blantyre, and it is greatly to be desired that the promoters of the two projects should come to some understanding.

In accordance with a resolution passed at the last meeting of the London County Council, a joint committee has been formed of the Parliamentary and Water Committees of the Council for the purpose of considering and dealing with the various Bills relating to the water questions coming before Parliament during the ensuing session. The joint committee has drawn up a report on the Staines Reservoirs Bill, the New River Company's Bill, and the Southwark and Vauxhall Company's Bill, in which power is sought to obtain the supplemental supply of water required for London by drawing on the river Thames and its tributaries, and by pumping water from Hertfordshire and Middlesex. The committee consider that the several Bills deposited by the water companies must be regarded as a definite attempt to obtain such new statutory powers as might enable the companies for many years to escape coming under the purview of Parliament and the local authorities, while the result of the companies obtaining such powers would be a large addition to the cost of purchase. Of course the committee are strongly of opinion that the Bills must be opposed by the Council.

EXPERIMENTS WITH KRUPP ARMOUR PLATES

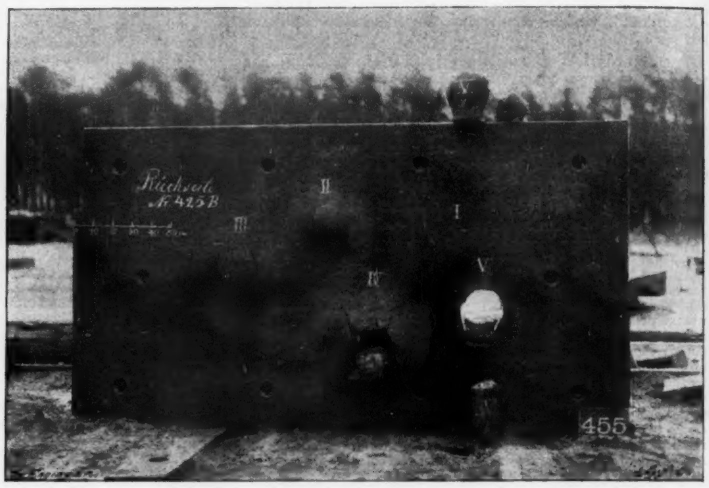

Fig. 4—BACK OF PLATE, FIG. 3

KRUPP'S ARMOUR IN 1894-1895.

WITH a short notice of a paper in *Stahl und Eisen*, by J. Castner, September 15th, 1895, are given in a pamphlet prints of photographs of results obtained by Krupp's armour within the year. We have, as well as the copies of this pamphlet, obtained in answer to our request, actual photographs furnished by Herr Krupp. We propose to deal with these rather more fully than we should usually do in support of the assertion which we have made that, in spite of the excellent work of our manufacturers, our neglect of nickel, and our want of system in grappling with the question has caused other nations to get ahead of us in armour, especially, we fear, in the manufacture of thick plates.

In the pamphlet to which we refer, is mentioned the fact that all nations, except England, have pushed on with the manufacture of nickel steel armour. Success was obtained with nickel and chromium by St. Chamond, but nickel only was adopted by the United States. Difficulties of blow-holes and blisters are referred to, but these, while they interfered but little with the actual strength of the armour, have been in a great measure got over, and armour-plates have been turned out by Messrs. Krupp free from them. Captain Sampson's opinion is quoted as to the beneficial effect of nickel, both in increasing the depth of the carbonising action and in giving security in the final water hardening. The difficulties and disappointments at first experienced with thick plates are referred to. These have been at length overcome, but it has been found that metal for treated and water-hardened faced armour must be more carefully selected than for that which is for oil tempering. There is a liability during cementation to the formation of blisters and flaws, which may be developed seriously in subsequent forging. Thick treated plates, however, have been at length successfully produced on both sides of the ocean with care and experience. It has been found important to prevent the production of gas arising from the action of carbon on an oxide film on the metal; also rapid carbonisation has been found to destroy the fine grain in the metal and to produce large crystals like those in cast iron. Instead of wood charcoal animal charcoal has been used in America, the surface of the plate being covered with it to a depth of from 12 mm. to 15 mm.—4¾in. to nearly 6in.—over which is laid the usual charcoal mixture. The Grambow process is mentioned, and the Creusot process of carbonising by means of ordinary illuminating gas. The results obtained by the Creusot process have not been published, and Captain Jaques guesses that Krupp uses a similar process; but how far this guess is correct is not stated. Gas is, however, said to offer the following advantages over charcoal in any solid form:—First, its action is more even, and gives greater uniformity; secondly, it is more certain or sure; thirdly, its action extends deeper; fourthly, it takes a shorter time; fifthly, it does not need so high a temperature. Consequently, it improves the quality of the plate and saves expense. A system is noticed which was tried in the States—we presume, that of Lieutenant Ackerman—of grooving plates before carbonising them, in order to make this action penetrate more easily into the plate. The success of these plates is not established; but it has been proved, and additional evidence to the same effect is furnished by the experiments with which we are about to deal, that furrows in the face of a plate do not predispose it to fracture, nor influence the direction of lines of fracture when the plate is broken. Gruson proved the same thing with regard to the surface furrows which are found on chilled iron castings; and Whitworth experiments are referred to, which proved that steel plates in whose surfaces a network of artificial cracks had been made, resisted as well as plain plates. Indeed, in one case the grooved plate was the best. The hardening action has been at length successfully graduated into the tough foundation, so as to avoid the danger of producing a hard layer which would scale off, and the depth of metal rendered too hard to drill has been brought to from 20 mm. to 30 mm. (7·9in. to 11·8in.). The account of the success achieved by Carnegie's double-forged 14in. plate for the Oregon line-of-battle ship, tried at Indianhead, is remarked on, which has been compared with one of Krupp's of 300 mm. (11·8in.) thick, tried on March 16th; which comparison, the writer observes, should have resulted in the superiority being accorded to Krupp. We do not note the elements of this comparison here, because we wish to devote our space to the more important matter of actual accounts of the trials following, which took place on December 15th and 17th, 1894, and on March 15th and 16th, 1895, in the presence of representatives of the German navy.

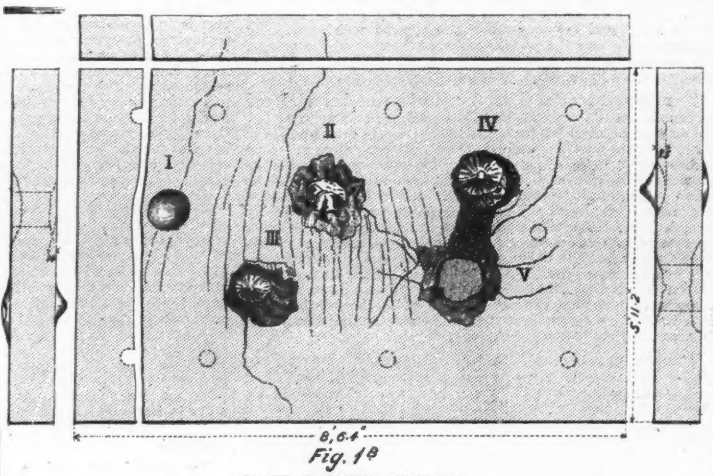

Fig. 1ᴮ

PLATE SHOWING FISSURES

Figs. 1 and 2 show the effect of an experiment made to ascertain whether a number of hair furrows or surface cracks—twenty-six in all—developed in a 146 mm. (5·75in.) plate in manufacture, acted injuriously on the plate under trial. The plate, No. 413 II., was 2·73 m. × 1·5 m. (8ft. 11·1in. × 4ft. 11in.) treated Krupp nickel steel plate. It weighed 4580 kilos (4½ tons). It was held up by ten 65 mm. (2·6in.) bolts. The following rounds were fired at it, with armour-piercing steel projectiles:—

No of round.	Calibre in		Weight of projectile.	Striking velocity.	Calculated perforation through iron.	
					Fairbairn or Maitland.	Tresidder.
	c.m.	in.	lb.	f.s.	in.	in.
I. ...	15	5·9	112·4	1560	10·4	10·2
II. ...	15	5·9	112·4	1891	12·8	13·6
III. ...	15	5·9	112·4	1734	11·7	11·8
IV. ...	21	8·27	209·4	1431	10·9	10·3
V. ...	21	8·27	209·4	1641	12·7	12·6

It will be seen by Figs. 1 and 2, that only Rounds II. and V. perforated. The shot most nearly matching the plate is No. III., and the resistance is very good. The

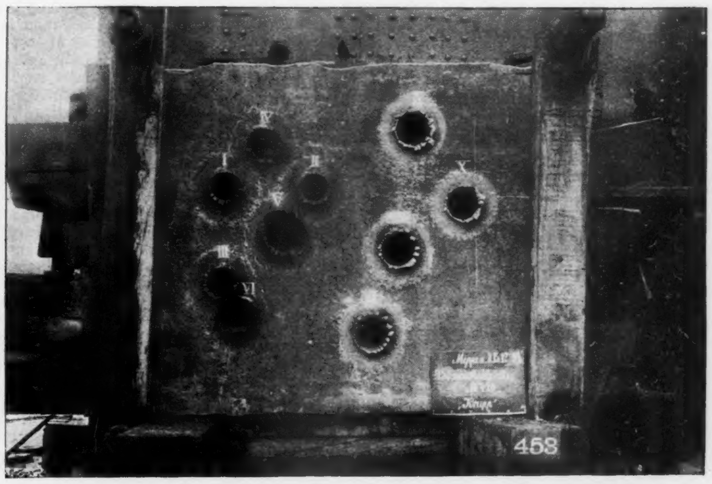

Fig. 10—PLATE FIG. 9, AFTER FOUR ADDITIONAL ROUNDS

actual equivalent of wrought iron suggested on best authority perhaps is $1\frac{7}{8}$in. the thickness of the treated steel, so that we may consider a treated plate which is equal to double its thickness of wrought iron a very good one. In this case, then, the plate would be a first-class plate if it was equal to 11·5in. of wrought iron. That it resists the passage of a projectile of 11·7in. or 11·8in. calculated perforation shows that it possesses remarkable excellence. The fissures ran down the face in nearly parallel lines; they are not very easily seen in the photograph, but are shown in Fig. Iʙ. It is evident that they produced no effect, for the only cracking developed by the attack consisted in a few more or less radial cracks from Round V., and one or two others from III., II., and I.—see Fig. Iʙ. Space forbids giving effects in more detail. Fig. 2 shows the back with a bulge partly opened at III., clean holes at II. and V., and bulges at I. and IV.

Next comes a plate, No. 425ʙ, of the same dimensions, and presumably similarly treated in manufacture, as it is termed a sister plate, but weighing 4760 kilos. (4 tons 13·6 cwt.) This was attacked by the rounds shown below, with results given in Figs. 3 and 4.

No. of round.	Calibre in		Weight of projectile.	Striking velocity.	Calculated perforation through iron by Tresidder.
	c.m.	in.	lb.	f.s.	in.
I.	15	5·90	112·4	1560	10·2
II. ...	15	5·90	112·4	1890	13·5
III. ...	21	8·27	211·0	1562	11·8
IV. ...	21	8·27	210·5	1627	12·5
V. ...	15	5·90	112·4	2022	15·0

It will be seen that rounds IV. and V. perforated the plate; the others were defeated, breaking up without getting through. Fig. 4 shows clean holes for IV. and V., bulges partly separated for II. and III., and insignificant for I. Round II. is the case of the greatest perforation defeated, being, as shown in table, 13·5in. of iron, which bears a ratio of 1·16 to the thickness of the plate. This argues considerably still greater power of resistance than that of the first-mentioned plate. Round III. delivered the greatest breaking shock, the total striking energy being 7424 foot-tons, or 1584 foot-tons per ton of plate, which is a very severe tax. Most of the attacks on modern steel plate have consisted in blows with great perforating power but insignificant shock, seldom exceeding 500 or 600 foot-tons per ton of plate. This, then, is a shock out of all comparison with that to which plates have generally been subjected.

The next trial given is that of a plate numbered 432 V, 300 mm. (11·81in.) thick. The area was 20 m. × 1·8 m. (6ft. 6·7in. × 5ft. 10·8in.) Its weight was 7·83 tons. It was held up by bolts 80 mm. (3·15in.) thick of nickel steel entering 50 mm. (2·0in.) into the plate back. The following rounds were fired at it. (See Table C in next page).

Figs. 5 and 6 show the results of this attack. The projectiles all broke in the plate face; the greatest test for perforation is the last blow, having a calculated perforation of 24·5in. of iron, or 2·27 times the thickness of the plate. The greatest shock is that of the first round, whose striking energy is 11,500 foot-tons, or 1469 foot-tons per ton of plate, the weight of the latter being 7·83 tons.

Krupp's report calls attention to the fact that projectile No. III. struck 430 mm. (16·93in.) from the side, and 360 mm. (14·17in.) from the bottom, and severely tested the toughness of the plate. Two small cracks were developed, but the plate held wonderfully well together.

TABLE C.

No. of round.	Calibre in		Weight of projectile.	Striking velocity.	Calculated perforation through iron by Tresidder.
	c.m.	in.	lb.	f.s.	in.
I.	28	11·02	508·4	1813	19·9
II. ...	21	8·23	305·1	2174	23·3
III. ...	21	8·23	305·5	2240	24·5

We now pass on to the most remarkable plate of the series, No. 432 U. Its dimensions were 3·0 m. (9ft. 10·1in.) × 1·90 m. (6ft. 2·8in.) × 300 mm. (11·81in.) It weighed 13·27 tons. The following rounds were fired at it:—

No. of round.	Calibre in		Projectile weight.	Striking velocity.	Calculated perforation through iron by Tresidder.
	c.m.	in.	lb.	f.s.	in.
I.	30·5	12·01	716·1	1753	21·5
II. ...	30·5	12·01	715·4	1889	23·9
III. ...	30·5	12·01	712·7	1993	25·9

The whole of the projectiles were broken up without effecting perforation, as shown in Figs. 7 and 8. There were no serious cracks. Round III. was a tremendous test, both as to perforation and shock. The rate of the calculated perforation, 25·9in., of iron to the thickness of the plate, is 2·19. The striking energy—19,630 foot-tons—amounts to 1479 foot-tons per ton of plate. The plate has entirely defeated the attack, and may be fairly claimed as exhibiting an extraordinary union of hardness and toughness. We take it to be the best result that we have ever seen, not only because it has exhibited extraordinary qualities, as shown by the above figures, but also because being a thick plate these qualities are exhibited under the conditions which make them specially difficult of realisation. We only see two grounds on which what has been said could be in any way qualified. One, it may be objected that the projectiles are perhaps inferior to those used in the States or elsewhere. This is a question that could only be solved by a competition. The Wheeler-Sterling shot in the States have performed the greatest feats that we have heard of, but only competition would prove that Krupp's are inferior; and very inferior indeed would these projectiles have to be to make the plate before us anything but a very extraordinary one. A more reasonable objection, and one that ought in justice to be made—and to give him his due, the writer of the report raises the very question himself—is that this plate is a champion one, made only for attack, and not, like the American plates, samples taken from a supply for ships. The gist of this objection lies in the fact that the treatment of plates must necessarily be hampered by the circumstance that they have to be shaped to an exact form. Allowance on this score may be freely conceded. The plate may very well take its stand on its merits as a champion plate. It is added in the report that the excellent plate with treated face exhibited by Krupp at Chicago, and noticed in our report on the same, was produced by metallurgical means which could be applied to a plate which was required to be brought to any desired form.

The last plate whose trial is reported is of a totally different character, being an untreated nickel plate 8ft. 6·4in. × 5ft. 11·3in. × 6·10in., weighing 5 tons 6·1 cwt. This was subjected to an attack shown in the following table:—

No. of round.	Calibre in		Weight of projectile.	Striking velocity.	Calculated perforation through iron by Tresidder.	Penetration achieved.	Effect.
	c.m	in.	lb.	f.s.	in.	in.	
I. ..	12	4·72	57·32	1641	8·8	7·0	Projectile set up 0·35in.
II. ..	12	4·72	57·32	1690	9·2	7·2	Projectile set up 0·43in.

This plate had thus borne, it is observed, blows whose total striking energy amounted to 5109·9 m.t. (16,500 foot-tons). The breaking up of the 12 c.m. projectiles as the velocity increased, caused the conclusion to be arrived at that they were overmatched by the plate; and the 17 c.m. appearing, on the other hand, to be an overmatch. The last four rounds were fired with the 15 c.m. gun. The plate showed no cracks—see Fig. 9—and the metal exhibited the usual even fringed edge to the holes, the concentric discoloration and other phenomena common to sound, even untreated steel under severe treatment having received blows amounting to 3113 foot-tons per ton of metal. The report concludes by observing that this plate showed remarkable qualities, having remarkable toughness, combined with an amount of hardness which offered great resistance to penetration.

In this verdict we fully concur. It will be seen that projectiles whose calculated power of perforation was over 10in. of wrought iron or 8in. of ordinary steel, and in one case 11·4in. of iron or 9·1in. of steel, and which should, therefore, have easily perforated this untreated plate, whose thickness was only 6·1in., were stopped by it, although they got their points through. It is a little difficult to make out what the backing was. It appears to have been changed and the plate set up anew after the sixth round. Judging from the photographs it consisted only of wood baulks set up vertically in the first instance and horizontally in the second. These may or may not have received support from structures behind; it is immaterial which. It will be observed that the three projectiles fired with a velocity of 1894 foot-seconds or over, broke up, while the whole of the remainder set up more or less, the extreme limit being 0·81in. in length. We are inclined to think them rather soft, and not equal to those now made in the United States. We have seen the results of a trial when Krupp projectiles beat "all comers," and we should not like to speak positively, but we think that projectiles are now made which would refuse to set up thus on striking an untreated plate with a velocity of from 1340 foot-seconds to 1650 foot-seconds. We should prefer a projectile to break in preference to so behaving, and we think that projectiles now exist which would neither break nor set up sensibly under such conditions, but to establish this they need to be fired against the plates in question. Be this as it may, we regard this plate as the beau ideal of what is required for inland shields, which are intended to resist the prolonged breaching attack of siege guns of medium power; and certainly if plates approaching the standard of the previous plates can be placed on ship's sides, the German naval officers may indeed congratulate themselves on the excellence of their armour.

THE TYLORSTOWN EXPLOSION.

IT would be an undeserved reproach to engineering science to protest or admit that colliery explosions, with their always appalling death-roll, however few or however many, are an inevitable incident of the coal-mining industry, in the same sense, for example, as to fall on the field of battle is a recognisable risk of a soldier—his risk, his fate, and perchance his glory. There is commonly a mystery in these disasters; the better the pit has been regulated the greater is the mystery; and the calamity announced from Tylorstown this week would appear to be, more distinctly than the greater catastrophe at the Albion Colliery in 1894—according to the testimony of the most expert mining engineers on the spot—altogether inexplicable.

For a moment let us describe the position from its geographical and engineering points of view. The valley of the Little Rhondda strikes northwards from the Rhondda River at a point where the ancient watercourses trisect the best of the more modern developments of the Welsh steam coal beds. At the head of this once picturesque ravine, which until twenty years ago deserved its name of "the valley of ferns," Messrs. Davis sunk pits which are known now as the Ferndale, but were originally called the Bllaenclechan Collieries. In those almost virgin seams terrible explosions occurred in 1867 and 1869. They were then the only sinkings in a district which has since been proved to contain one of the richest, and at the same time the fieriest steam coal beds in the kingdom. The Standard Colliery, the National Colliery, the Boedringallt, have subsequently been opened. The managers in each case knew the dangers; they took precautions; they adopted every scientific safeguard as it made its appearance; and yet every pit in the little valley has been the scene of a more or less dreadful explosion, except that at Ynishir.

The Tylorstown pits had been sunk to the southern dip of the Ferndale seams, and the working of the coal from the time that Tylor Brothers began this enterprise was always as safe as it turned out in the end to be lucrative. The Tylor property was transferred to the hands of David Davis and Co., Limited, and since then the workings of the two collieries, which had before almost impinged on one another, have been made physically and geographically continuous, though the output has been kept distinct, and the coal won in each was brought up distinctly from the four shafts of the Ferndale and the separate shafts of the Tylorstown pits. Roughly, one might say, you could walk more than four miles through underground roadways, from the southern shaft of the Tylors' colliery to the northern shaft of the Ferndale pits. And this enormous subterranean area was continually watched with the same vigilance as a Kimberley overseer surveys his diamond deposits; supervised by the best men whose services could be retained by high salaries; supplied with every device which science could suggest for the free and ample ventilation of the roadways and headings. It was but the other day that we were told by mining amateurs that every colliery should have three shafts, which is well enough in its way, only the amateur used to insist that the upcast shaft should always be at the "face" of the workings. Even the Home-office, when there were then no colliery experts—and it is doubtful if Sir Matthew Ridley has yet a colliery department attached to his staff—laughed at the idea of making a new upcast for every year's advances into the "face'6 of the coal measures. But at Tylorstown there were three shafts, and at the upcast there was a Schiele fan, which was thrown out of gear for a couple of hours as one of the effects of the explosion. Despite of the interruption of the fans, and with the doorways separating the Tylorstown workings from the Ferndale workings, it is to be inferred that the ventilation of the Tylorstown Colliery continued to receive a supply of air, or so many men would not have been enabled to reach the downcast shafts in safety, and Mr. Hannah, the manager of the Ferndale and Tylorstown pits, could not have made his heroic march—as brave a march as anything done in war—from seven in the morning until three in the afternoon, throughout the labyrinth in search of the poor fellows who might still be succoured from the effects of the deadly afterdamp.

But here is a problem for the mining engineer who has combined chemistry with his other attainments. In two or more instances Mr. Hannah, the manager, in his perilous exploration of the shattered mine, climbed over falls to be encountered by groups of colliers with their lamps alight. The men were dead, and had died painlessly; there were the lamps in the midst of their peaceful circle, still burning as vividly as a shielded Clanny will ever burn, in the opaque interstices of the pit. Mr. Hannah, with his three brave companions, had to go back thrice to the inlet of fresh air to give his lamp a light again. He went back with a re-illumined wick, and found a ghastly group around the still lighted hooded Clanny lamps. The mystery of the explosion is not greater than the mystery as to how or why the spark of life in the lamps should live when the human spark of life had fled. There were cases in the western part of the workings in which men were found with their clothing torn off them by the blast, which is interpreted to mean that the explosion broke out there; but it is in the mid-distance, and also to the eastward, where the men were found as though they had just sat down to rest until a sudden "fall" had been removed from the shaft side. These men on the eastern side could not have heard the full volume of the sound of the explosion, and then the afterdamp reached them, and there, where they sat, they became at rest for ever.

THE KANE-PENNINGTON MOTOR.

THE Kane-Pennington motors illustrated in our impression of the 3rd inst., and the Racine carriage and a bicycle driven by these motors, have lately been exhibited at Brown's Grounds, Nunhead, where we have had an opportunity of inspecting them. The motors as used for the bicycle and for the four-wheeled carriage have two cylinders, as shown at page 3, and two pairs of cylinders respectively. Those used on the carriage have pistons 2·5in. diameter and 6in. stroke, working in water-jacketed cylinders, the water circulation being natural, and the water supply being kept in a cylinder along the front of the carriage beneath the oil receiver, shown by Fig. 12, page 3. The four-cylinder motor has been removed from the carriage since it reached this country, and a two-cylinder motor similar to that used on a bicycle, but with a water-jacket, put in its place. The motor is extremely lightly made in nearly all its parts, and drives an intermediate shaft by means of a strong bicycle chain. On this shaft are a compensating motion and two friction clutches for two different speeds, the motion being conveyed to the road wheels of about 24in. diameter, with very large pneumatic tires, by means of light bicycle chains. The hydrocarbon used in the cylinder falls by gravity into a little receiver on a pipe connecting the two cylinders, and its quantity is regulated by a little hand valve under the seat. This hand valve and the two friction clutch levers and the switch for the ignition spark current are all easily reached by one of the two riders on the seat of the carriage. Most of the features of the motor are decribed in the specification of the patent of Mr. Thomas Kane, No. 20,305 of 1895, but some improving modifications have been made in the electrodes used in the cylinders for the ignition of the charge by electric spark, the spring wire or elastic contact piece being on the electrode inserted in the cylinder, instead of on the end of the piston. The cam circuit maker on the crank shaft is replaced by a commutator on the crank shaft, formed with brass strips on a circular piece of vulcanised fibre. When the piston on its in-stroke compresses the charge of air and vapour from the hydrocarbon, and when its stroke is very nearly completed, and full compression pressure nearly reached, the rigid electrode on the piston body comes into contact with the elastic insulated electrode, and a spark is formed. On the return of the piston this contact is, of course, repeated, the two make and break sparks occurring within the time occupied by the piston in moving about a quarter of an inch. If the explosive mixture is not ignited on the in-stroke of the piston, as perhaps it usually is, the second spark prevents any chance of a misfire and of a consequent back ignition. At the very high speed of about 500 to 600 revolutions per minute, a little lead in the ignition is always desirable, and the spark made on the ingoing make and break is desirable in this respect. The battery used by Mr. Pennington consists of from ten to twelve small dry cells occupying little space.

Mr. Pennington shows the carriage at work, driven at high speed by this little two-cylinder motor, and carrying four persons over good, bad, and very rough roads, and soft grass covered ground, and he shows by it that such a light carriage may be operated by small power and light mechanism. Some of the details of his motor are very much lighter than English engineers would think of using for the purpose, and probably he will make some modifications in this respect. The kind of hydro-carbon used will be gathered from a consideration of the details of the engine, and we understand that in a short time Mr. Pennington will show in Holborn how he uses the heavier oils, such as Russolene or Tea Rose, in his new motors.

EXPRESS PASSENGER ENGINE—MIDLAND RAILWAY.

IN our impression for December 13th, 1895, we published an external elevation of one of the four coupled express engines, designed and built by Mr. Samuel Johnson, for working the fast traffic of the Midland Railway.

We now publish an end view and cross section of the same engine as a supplement. For full particulars, we must refer our readers to our issue of December 13th, before mentioned.

RAILWAYS IN CHINA.—The Leeds Chamber of Commerce recently received a report on the respective advantages of the Kunlon Ferry Railway and Railways leading to Szumao. That report has been sent to the Under Secretary for Foreign Affairs, with a request that the attention of Lord Salisbury may be drawn to the conclusions, which are:—"Owing to the character of the intervening country, which belongs to China, there is apparently not the slightest reason to hope that the Kunlon Ferry Railway can be extended eastwards to Szumao, or north-eastwards to Tali-fu. With a railway from their Tonquin seaboard to Szumao, the French would gain the trade of Southern Yunnan, which we have learned is the richest part of that province of China, containing as it does all the large plains, cities, and towns; they would be able to push on the projected extension of that railway from Szumao through Yunnan, and would be assured of attracting to a French port the trade of the landlocked western half of China. If we should fail to make a railway from a British seaport to Szumao, we could not compete with the French in facilities. We should have to resign ourselves to a trade with a sparsely populated, barren, wild upland, which possesses little means of communication, and which would not open up to us any important outlet or inlet for the trade of Yunnan. By the cession of parts of the Shan State of Kiang Hung to France, the Chinese Government has shown either want of will or powerlessness to protect that State from French aggression. This being the case, the breach of its engagement with this country has, we would submit, absolved us from carrying out our part of the Burmo-Chinese Boundary Convention. We have thus the power to resume our rights to the Burmese Shan States of Kiang Hung and Munglem. By bringing Kiang Hung again within our dominions, and by arranging with Siam for the return to us of a small track of territory neighbouring Kiang Hsen, the Burmah-Karenni-China Railway can be made from Rangoon to Szumao entirely through British territory, without encountering inordinate physical difficulties. If these steps are taken by her Majesty's Government, and the Burmah-Karenni-China Railway is constructed, important military, administrative, and commercial advantages will accrue to our Indian Empire.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

⁂ In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.

⁂ All letters intended for insertion in THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

⁂ We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.

WEATHER AND DISEASE.—*The Graphotone Company, 1, MacLean-buildings, E.C.*

J. M.—*You can get full particulars by applying to the Marine Department of the Board of Trade, Whitehall. Reed's "Handbook," a well-known publication, is used for passing the examinations. It is published in Sunderland by the author.*

H. AND SONS (Norwich).—*You do not give particulars as to the quantity, but there can be no difficulty in blowing the dust directly into the furnace above the fire-bars. If you send it into the chimney it will not be burned, and may cause a nuisance. No screen would be needed. If the arrangements are properly carried out, the blast of air over the fire will act to prevent smoke. A small steam jet may be used, or a fan, as most convenient.*

COKE SCREENING MACHINERY.

(*To the Editor of The Engineer.*)

SIR,—Can any reader give me any information of any machine that will economically separate coke from cinders? W.

Liverpool, January 27th.

HARDENING STEEL TO CUT HARD STEEL.

(*To the Editor of The Engineer.*)

SIR,—Would you please allow me to ask in the correspondence columns of THE ENGINEER, how to harden a drill to cut through a hard file? Milling tools are often made on this principle. Reamers and other tools are cut out of self-hardening steel after hardening by some means.

Camberwell, January 27th. TOOLMAKER.

LEATHER DRESSING MACHINERY.

A CORRESPONDENT in Barcelona, Señor J., wishes for information about skin and hide dressing machinery, with figures and details as to prices. Address Señor José Julia, San Juan de Horta, Barcelona, Spain.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

⁂ The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, February 4th, at 8 p.m. Paper to be further discussed: "Recent Developments in Gas Engines," by Mr. Dugald Clerk, Assoc. M. Inst. C.E.

SOCIETY OF ENGINEERS.—Monday, February 3rd, at 7.30 p.m. The President for the past year, Mr. William George Pierce, will present the premiums awarded for papers read during the year. The President for the year 1896, Mr. Samuel Herbert Cox, will deliver his inaugural address.

INSTITUTION OF JUNIOR ENGINEERS.—Monday, February 3rd, at 7.30 p.m. Lecture I. of special course of Marine Engineering Design, by Mr. H. M. Rounthwaite, M.I. Mech. E., M.I.N.A.

SOUTH STAFFORDSHIRE INSTITUTE OF IRON AND STEEL WORKS' MANAGERS.—Saturday, February 8th, at 7 p.m. Paper: "Technical Instruction in its Application to Ironmaking," by Mr. Thos. Turner, A.R.S.M., F.I.C., Director of Technical Instruction to the Staffordshire County Council.

GEOLOGISTS' ASSOCIATION.—Friday, February 7th, at 8 p.m. Paper: "Some Structural Characteristics of the Granite of the North-West Himalayas,' by Lieut.-General C. A. McMahon, F.G.S.

SOCIETY OF ARTS.—Monday, February 3rd, at 8 p.m. Cantor Lecture: "Alternate Current Transformers," by Dr. J. A. Fleming, F.R.S. Tuesday, February 4th, at 8 p.m. Applied Art Section. Paper: "The Garden in Relation to the House," by F. Inigo Thomas. T. G. Jackson, A.R.A., will preside. Wednesday, February 5th, at 8 p.m. Paper: "The Mexican Drainage Canal," by Frederick Henry Cheesewright, M. Inst. C.E.

DEATHS.

On the 26th inst., at 35, Upper Tollington-park, ARCHIBALD STURROCK, son of the late JOHN BUDGE, formerly Locomotive Superintendent, Great Northern Railway, age 43.

On January 22nd, at 8, Buckingham-street, Strand, DANIEL KINNEAR CLARK, M. Inst. C.E., M. Inst. M.E., &c., aged 74 years.

THE ENGINEER.

JANUARY 31, 1896.

THE ROYAL ORDNANCE FACTORIES.

IN a recent article on the constitution of the Ordnance Factories, we showed that the inception of warlike stores, and their final inspection and sentence, was entirely in the hands of naval and military men, and that it was, consequently, absurd to state that the naval and military authorities had lost touch with the factories. The actual manufacture, only, is under a civilian Director-General, but space prevented us from pointing out that, with the exception of the Small Arms Factory at Enfield, the Superintendents and their assistants were still all naval or military officers, and have remained so since the reorganisation carried out by an officer of the artillery in 1887. A colonel of artillery and two captains of the same arm manage the Royal Laboratory; a captain of the Navy and a lieutenant manage the Royal Gun Factory; a colonel of engineers is responsible for the Royal Carriage Department; a colonel of artillery, a captain, and a lieutenant, are responsible for the Royal Gunpowder Factory; and a colonel of artillery manages the factory in Birmingham. The Director-General has two military assistants, one a commander in the Navy, and one a captain in the artillery, and it would thus appear that he is assisted by no less than twelve officers of the Army and Navy, and therefore if the work turned out to be bad and dear—as it is alleged to be by the writers in the *Times*—that circumstance seems to us to be a strong argument in favour of the proposition that military and naval men are unfit, from want of technical knowledge and special training as manufacturers, to carry on manufacturing operations, and confirms the view which we have expressed of the imprudence of placing important factories under such management, and thus severely hampering a competent civilian Director-General.

It may, indeed, be pleaded that the cause of the alleged bad results is the incompetence of the Director-General, and that if he were replaced by an officer of artillery who, of necessity, could have had no technical training or experience as a manufacturer working for profit, the ordnance factories would once more resume their former supposed efficiency, by which we presume that they would revert to the condition which called forth the inquiry instituted by Lord Morley's committee, whose report it was that prompted the reorganisation now complained of. We are not concerned to defend the fitness of the present Director-General for the office he fills, we can only say that Mr. Stanhope selected a man who had achieved for himself a high position in the engineering and scientific world, and who had for thirty-six years managed successfully large manufacturing concerns engaged in the production of a great variety of things.

We must point out that there are two ways of managing a factory. One is to be the real head, to know more of every detail than any of the subordinates, and to be able to make such dispositions as will reduce the cost of production without endangering the quality.

The other method is to become a nominal head, nursed by the civilian managers and foremen, and acting really according to their direction, and as their mouthpiece. To the second category the military chiefs of necessity belong, and experience has shown that it is only in exceptional cases that an officer's natural talents and proclivities enable him, after a time, to take up a proper position. Such a man was General Maitland, who had served a good apprenticeship in the gun factory before he was charged with the duty of reorganising the factories, and it is well known that he strongly advocated working the shops by means of trained civilian managers.

In our judgment no substantial improvement in economical management is to be looked for till there is a complete separation between the military advisers of the Director-General and the civil assistants who are charged with the actual carrying out of the work and the keeping of the accounts; and we sincerely trust that in the administration of the factories the present Government will faithfully carry out the principles laid down by the last Conservative administration, and loyally acquiesced in by their Liberal successors, who, we may remark by the way, were so satisfied with their predecessors' choice of a Director-General, that one of their last acts was to recommend him to the Queen for special honour.

CONTINENTAL COMPETITION AND RAILWAY RATES.

IN our last impression we directed attention to some of the more important features of the report of the delegates of the British Iron Trade Association on the iron and steel industry in Belgium and Germany. A great deal remains to be said. Indeed, the more carefully the report is examined, the more prominently do subjects for discussion thrust themselves on our notice. One of the most interesting is the statement already referred to in our columns, that English manufacturers are handicapped, as compared with Belgian and German iron and steel makers, by the cost of transport. Many examples are given. Thus the rate per ton for finished iron and steel on English railways, for large quantities, varies between 1·06d. and 1·415d. per mile, which is about three times the Belgian rate. We need scarcely insist on the importance of cheap carriage in every trade. But, on the other hand, it will not answer any good purpose whatever to denounce railway companies, and assert, as has been done, that they are ruining the iron and steel trades of the country. The proper course is to take all the available evidence, and estimate the value of the facts by their significance and pertinence to the matter at issue. In this way—and only in this way—can sound conclusions be formed.

At first sight it no doubt appears that if a ton of iron can be carried 150 miles for 3s. 6d. in Belgium, it cannot be right to charge 12s. 6d. for carrying a ton of iron 134 miles in this country. There are two explanations of the fact. One is that the English railway companies charge a great deal too much; the other is that they manage their business so badly that they cannot charge less. That, in short, they waste money. We think the first count may be dismissed at once, if for no other reason than that extortion would not pay. The other argument seems to be equally devoid of foundation. It is not possible that the able men who conduct traffic on English railways would blunder continually to such an extent as to waste two-thirds of the receipts for goods. Again, it must not be forgotten that a railway is a commercial enterprise, and that it is quite as important that our railways should pay as it is that our iron and steel trade should be prosperous. The capital invested in railways is, indeed, very much larger than that invested in the blast furnaces and rolling mills of Great Britain. There are two reasons why railway carriage is cheaper in Belgium than this country; one is that it is much slower as regards goods, and another is that many of the railways are State property, and consequently profit becomes a secondary consideration. No doubt it would be possible, if the State owned the railways in this country, to reduce the cost of transport very much. Roughly speaking, working and maintenance expenses are 55 per cent. of the total receipts; the remaining 45 per cent. goes to pay dividends, and it is well known that these dividends are in no case excessive, and in many cases very small. The fact that the Belgian State railways can afford to carry at very low rates is precisely akin in many respects to the action of the German Government in giving a bounty on sugar, and is entirely opposed to all the principles of free trade. It might, of course, be argued that the nation at large ought to make arrangements for the cheap transport of coal, iron, and such like; but it is clear that if the railway companies do not make more than a legitimate charge now, to do anything of the kind would be simply to subsidise an industry, while any legal enactment reducing the cost of carriage in such a way that dividends would be reduced as a consequence, would simply be to rob Peter to pay Paul; to, in a word, take money out of the pockets of one set of shareholders and put it into the pockets of another set. Beyond question this is done in Germany and Belgium, where the community is taxed to support special industries; but the practice does not commend itself to the British mind, and we fancy that in this direction the iron and steel trades will get no relief.

But although we may exonerate the railway companies from the charge of extortion, it does not follow that they are wholly blameless. It remains to be considered whether it is not possible to reduce the cost of carriage in this country. In approaching this very difficult and complicated question, many points must be weighed. In Belgium, for example, we have a very flat country, and haulage can no doubt be effected with a minimum expenditure of power. We find, too, that the rates are anything but uniformly low. Thus, while Germany can send iron through Belgium to Antwerp, 150 miles, for 3s. 6d. per ton, Couillet has to pay 3s. per ton for sending it 70 miles only to the same port. But the bare statement made in the report is very inadequate. We are not told whether carriage is effected in private wagons, or in those of the railway company; nor is a syllable said concerning terminal charges. A most important factor in the whole question is the quantity of iron or steel or coal to be moved, and the accommodation available for moving it. It should be quite well known that in this country many of our railway companies are at their wits' end to accommodate traffic which is enormous as compared to anything to be met with on the Continent. Bristol station, for example, on the Great Western Railway, has been congested for years, and a very large recent outlay has been necessary to secure some relief. Most of our main lines have been doubled for long distances at great expense. But there are districts where it is next to impossible to provide greater facilities than now exist, because of the difficult nature of the country to be traversed. Belgium, on the contrary, is an ideal railway country, and in Germany, while much of it leaves nothing to be desired in this respect, the Government provides, at the cost of the taxpayer, cheap transport. It is very difficult for the outsider to realise the magnitude of the operations carried on on English railways. At Edge Hill, on the London and North-Western Railway, there are more than 60 miles of sidings and space for 7000 wagons. Where can we find abroad a railway company owning 70,000 wagons? One of the principal complaints urged against our railway companies is not that they charge too much, but that they will not forward goods. It is not extreme to say that most of the railways in the country which have anything of importance to do in the way of transporting finished iron and steel and coal, have usually about as much traffic as they can conduct with certainty, comfort, and despatch, on the present system. It remains to be considered whether the present system is the best that can be adopted.

We cannot find that there is anything about the management of Belgian or German railways to encourage the belief that a substantial reduction in working expenses would be effected in this country by assimilating our practice with theirs. It is much to be regretted that on this subject the report before us is silent. Nothing is said as to systems of loading and unloading, locomotives, wagons, &c. With the general facts we are, of course, familiar. The principal difference between transport practice in the three countries is that the engine coal used in Germany and Belgium is much inferior to that used in this country; but the difference in the cost of coal is, after all, an insignificant item. It is possible that in this country a saving might be effected by using a more powerful type of goods engine than that now in vogue; but account would have to be taken with the Board of Trade before these heavy engines could be adopted, and the conditions suitable for their employment are far from being universal.

But a much more important question than the possibility of reducing railway rates suggests itself. How far do the present rates hamper operations and restrict trade? It is to be assumed that high cost of transport must do harm, but we want to know how much harm. On this point, again, the report is silent, singularly silent. "It seems difficult to understand," runs the report, "how works situated at Liége in Belgium, more than a hundred miles from a shipping port, and at Oberhausen, Dortmund, and Ruhrort in Germany, which are at least a hundred and twenty miles from tide-water, and having no advantage in the cost and the conditions of supply of ores and fuel, should be able to compete as they do with work of the same class and character in England situated upon or within a few miles of tide-water, as are most of the works in Cleveland, Scotland, Wales, and Cumberland." The answer given is that "one of the obvious causes is the low rate of transport which the works of both Belgium and Germany enjoy." The importance of the passage we have quoted lies in the value to be attached to the words "able to compete," and this can only be determined when we know something of the weight of goods affected by railway rates. It has been known for years that carriage was in certain ways and under certain conditions cheaper on the Continent than in this country. The report adds nothing to our information on the question. The bald statement that rates are lower, without hinting at the reason why they are lower, is most unsatisfactory. It is in the abstract extremely desirable that railway rates should be as low as possible, but to reduce them to an extent which would rob shareholders would be not only unjust but impolitic. On the other hand, however, it is not, we think, too much to suppose that good might be done by laying definite evidence before the railway companies for their consideration. Thus, for example, let us suppose that the steel makers of Sheffield combined together, and having ascertained all the facts, formulated a scheme by which the cost of transporting steel to shipping ports might be reduced, and submitted it to the directors of the principal railways concerned. Is it not to be supposed that such a scheme would form the subject for careful deliberation, and how much would the hands of the steel makers be strengthened if they could cite the example of Belgium or Germany in such detail as would be convincing? We fear that the delegates of the Iron and Steel Trades Association have missed a great opportunity. Nothing to be found in the works which they went out to examine could be of more importance than the details of the railway management of the two principal countries concerned. The report is in many ways calm, dispassionate, even colourless, but it contains statements, nevertheless, which may easily be twisted to support wild doctrines. If our railway companies allege that they cannot reduce the rates because of the high prices charged by the steelmakers for rails and axles, and the coalowners for fuel, they receive little sympathy. Yet, after all, it should be clear that the railway industry is at least as important and as deserving consideration as any other; and the companies may just as well say that the ironmasters are doing them harm as the ironmasters may say that railway rates are too high—there should be no waste on a railway, there should be no waste in an ironworks. If it can be proved that the English companies are spending more on transport than need be spent, then a change for the better ought to be made; but until this is done there is nothing to be gained by blaming the companies. Without suggesting a way to improve matters, we have already said that cheap transport is highly desirable. But if it can only be attained by cutting down wages, augmenting risk, and reducing the number of hands employed on our railways, the gain may not compensate for the loss. We do not say that there is no room for improvement. We do say that the report of the Iron and Steel Trades' Association does not help us, as it should, to a way in which rates may be reduced. The report before us may be taken as a basis for further action, but those seeking relief will have to complete their case; in its present aspect it amounts to a bald statement, implied rather than defined, that because railway rates are less in Belgium and Germany than they are here, the rates are too high in this country. This is not enough. The public must be told the why and the wherefore of these things before it can be in a position to decide between the iron trade aud the railway companies. More light, much more light, is wanted.

LONDON FIRES AND THE BRIGADE.

THE report addressed to the Fire Brigade Committee of the London County Council by the chief officer of the Brigade, Captain Sexton Simonds, on the fires in the metropolis during the past year, is remarkable as showing a considerable increase in the aggregate, and at the same time an exceptionally low percentage of serious fires. Never were fires so numerous, and yet we must go back seven years to find a lesser number of those which inflict serious damage. In 1866 one-fourth the fires were of a destructive nature; after 1878 they fell below 10 per cent., the average of the ten years ending with 1894 was 6·2 per cent., and last year the proportion went down to 3·9, the lowest percentage on record. It is satisfactory to find the ratio declining steadily rather than spasmodically. In 1879 it was 9 per cent.; in 1885 it was 7 per cent.; afterwards it was 6 per cent., then it became 5 per cent., and now we may call it 4 per cent. This is the more worthy of consideration, seeing that the total number of fires, year by year, has gone up at so great a rate. Until 1883, the fires were under 2000 per annum, until 1891 they were under 3000, and now in 1895 they reach 3633, being more than 1000 above the annual average of the previous decennium. Has petroleum anything to do with this? Mineral oil lamps are a fruitful source of fires on a small scale, and possibly they affect the statistics which appear in these annual reports. In the list of "causes of fires" for 1882, we find 120 cases attributed to the upsetting of spirit lamps. In 1895, 314 fires were caused by the upsetting of mineral oil lamps, 12 by the upsetting of spirit lamps, and 112 by the explosion of lamps described as burning mineral oil. Fires caused in various ways by lamps fed with mineral oil or spirit, omitting those in which there was simple contact with curtains or window blinds, were 152 in the year 1882, but were no less than 485 last year. It would therefore seem that the more extended use of mineral oil or spirit is having something to do with the astounding increase of London fires. Still the explanation is partial, the fires from all causes having increased by as many as 1707 since 1882.

A test which we have applied on former occasions in respect to the prevalence of London fires, is that of the ratio between fires and population. Fires were numerous in 1893, being then 3410, and the number per 100,000 of the population was 79. But the ratio last year was 82·72. In 1894 the number of fires dropped, and the ratio was not much above 70. The rise last year, therefore, was very decided. In 1892 the ratio was under 74. The year 1894 appears exceptionally good among the last four, but it has yet a higher ratio than that of earlier periods. In the sixteen years ending with 1880 the average annual ratio was little more than 48. The present Sir Eyre Shaw commenced to keep the record in 1866, and in that year the ratio was rather more than 44, while the average from 1848 to 1864 was 41. Allowing for some fluctuations, it is obvious that the general tendency in London is for fires to increase more rapidly than the people. The fires last year were more than double the number in 1879, but the population had increased by less than one-third. The most encouraging feature is the decrease in the number of serious fires, and this is a testimony to the efficiency of the Brigade.

In the report by the then Captain Shaw for 1867, there is the striking statement that the serious fires in London in 1865 were as many as 512, or fully one-third of the total. In that year London had simply a Fire Engine Establishment, and the Metropolitan Fire Brigade had not been created. A great enlargement of the force and its appliances began as soon as the Metropolitan Board took charge of the affair. How fearfully weak was London in protection against fire before this change took place, will be seen by the circumstance that in 1865 the firemen numbered only 129. In a single year the Metropolitan Fire Brigade made the number 230. In like manner 87 fire engines were substituted for 38, and 39 land stations for 17. Now the Brigade includes 820 firemen, 17 "pilots," and 75 coachmen, together with a troop of 137 horses. Instead of 38 fire engines, or even 87, there are 144, and 64 of these are worked by steam. The appliances compared with those of 1865 are immeasurably superior, as in the use of the telephone and the establishment of alarm call points, of which there are as many as 570. The multiplication of fire escapes tells of the increased security for human life, though fatalities from fire are still painfully numerous—the lives lost in this way last year in London being 91, while it is satisfactory to find that as many as 215 were rescued. Captain Simonds specifies that in 22 instances mineral oil lamps exploding, or being upset, caused 23 deaths. In Captain Shaw's report for 1867 we find only 21 fires brought about by sundry accidents with lamps, whereas nearly 500 are reported as occurring last year. Smoking tobacco caused 32 fires in 1867, and in this respect recent years seem to have witnessed an improvement, Captain Simonds only reporting 15 such cases for 1895.

The work of the Brigade, while replete with detail, is marvellous in extent. The number of journeys made by the fire engines and hose vans during the past year exceeded 36,000, and the total distance run was above 73,000 miles. The quantity of water used for extinguishing fires was more than 100,000 tons, nearly half of which was taken from the street pipes. It is a matter for regret that in the course of the year there were four occasions in which there was a late attendance of the turncock, and in one case there was no attendance at all. In four instances there was a short supply of water, making, as Captain Simonds says, "nine cases in all in which the water arrangements were not altogether satisfactory." Perhaps the water companies could give some kind of explanation, though they never seem to do so. What the arrangements are for calling the turncock we are not told. But the general system is excellent, and the Brigade deserve hearty commendation both for their toil and their courage. They are a gallant set of men, notwithstanding the disparaging remarks made concerning them within the compass of the County Hall, a quarter where unstinted praise might have been looked for. But the criticism is perfectly exceptional, and scarcely anyone can be brought to believe that the rank and file of the Metropolitan Fire Brigade are petted or spoiled. Never was London so dependent upon them for its safety as now, when the population is so vast, and buildings are assuming such enormous dimensions. The elements of danger which exist in modern society may also be taken into account, malicious damage being quite a possible outcome of social and political disaffection. The police on the one hand, and the Fire Brigade on the other, safeguard the metropolis against perils such as are peculiar to a highly developed civilisation and the visible growth of wealth.

◆

COAL.

THE Miners' Federation and the Federated Coalowners are engaging in a friendly warfare of words concerning the present position of the British coal trade. The president of the former body—Mr. B. Pickard, M.P.—in his recent address at Birmingham to its annual conference, sought to show that the coal trade was doing well, and was able to bear the present, if not indeed, an advanced rate of wages. The Federated Owners have this week replied in a long letter which they have had published in the chief newspapers in the kingdom. This is an unusual step to take, but the importance of the whole matter becomes evident when it is remembered that in a few months' time Lord Rosebery's agreement adopted by the Conciliation Board expires by lapse of time, and that juncture may be a critical one for the British coal trade unless care is exercised. Hence the coalowners feel that it is necessary that public opinion shall have before it, not an *ex parte* statement of the position, but a fair presentation of both sides. The Miners' Federation president relied mainly on the circumstance that the shares in several limited companies which he named are now quoted at a higher price than they were in the year 1888. The owners' association point out in reply, not only that in that year the coal trade was admittedly in a very depressed condition, but that within the federated area there are between 300 and 400 companies and firms, and the Stock Exchange quotation of the price of the shares of any particular company, or of any dozen companies, is scarcely sufficient material upon which to pronounce an opinion upon the general conditions of the entire trade. In comparing the selling prices of fuel for the quarter ending the 30th September, 1895, with the prices submitted to the Conciliation Board in the July of 1894, and upon which the Board recommended a reduction in wages of 10 per cent., it is found that selling prices have fallen very considerably in every district within the federated area, and in some cases by as much as 17 per cent. The returns for the December quarter are not yet complete, but the owners' secretary expects them to show a still further drop. The Employers' Association quotes the average number of days per week on which coal was hewn and wound during each of the twelve months from August, 1894, to July, 1895, in the various districts of the United Kingdom; and proves from these figures that the number of days within the federated district—bound by the agreement and by the high fixed wage—was considerably less than in the districts outside the federation. Thus, the federated owners, by paying a higher rate of wages and working so much less time, were saddled with an increased working cost compared with their outside competitors. The mean averages of days per week for these twelve months are:—United Kingdom, 4·72; Northumberland and Durham, 5·10; Yorkshire, 4·47; Lancashire and Cheshire, 4·64; the Midlands, 4·17; South Wales and Monmouthshire, 5·26; Scotland, 4·90.

CABLE REPAIRING AND CABLE DANGER.

THE value of the cable communication between this country and its colonies and the United States has been of late amply demonstrated; and some of the facts that have been brought to light of late show again the vastness of the resources of the great companies who now control these submarine communications. It may be remembered that just prior to the exciting events in the Transvaal at the beginning of the year, one of the cords of communication between Africa and this country was interrupted. The story of the repair is told by the Marquis of Tweeddale, who states that on the 24th December, the Aden-Zanzibar cable was interrupted, and who details the steps taken by which the repairs were completed and communication restored by the 4th January. There was one cable repairing steamer at Capetown, belonging to the company owning the cable, the Eastern and South African Company, but another cable steamer was near Aden, and that was chartered, and by its use "a saving of about a week could be effected," and thus the continuity of the wires was restored, and the enormous work that followed the crisis in the Transvaal could be met. It is only by lavish expenditure that such quick repairs can be met, and by the maintenance of large fleets of cable steamers—the Eastern Telegraph Company alone owning five, by one of which the Aden-Zanzibar cable was repaired. At the meeting of the Direct United States Cable Company, a few days ago, Sir J. Pender stated that the company had just repaired the cable on this, the European side, "which has been hanging on a rock for twenty-two years," a most "interesting illustration of the length of time a cable will wear hanging on a rock," but which is now avoided by the taking of the repaired cable round it. At the latter meeting, the question of the cutting of cables in time of war was referred to, but it seemed to be the general opinion that there would be, as the uses of ocean telegraphy extended, and as the duplication of cables and of routes proceeded, less and less danger in this direction. The incalculable value of that communication to the nations has been shown by the results of the action that it enabled to be taken, both in regard to the African and the American crises, and it would be a national danger now if, with the rapid land communication, there were not also a certainty of as rapid international communication by the cables.

LITERATURE.

Minutes of Proceedings of the Institution of Civil Engineers. Vols. cix., cxx., cxxi., cxxii. Edited by JAMES FORREST, Associate I.C.E., Secretary. Together 2026 pages, with 27 plates. London: Published by the Institution. 1895.

FOR the first time we have to record a reduction in the size of the yearly volumes recording the work of the Institution of Civil Engineers in the session just completed. This, however, is due to no diminution in activity among the contributors, but has been caused by the necessities of the new building operations which shortened the session by nearly six weeks in order that the alterations in the Theatre might be completed in time to render it available for use in November, 1895, and might, therefore, have caused a greater contraction than the 264 pages and 13 plates, which is the net difference between these volumes and their predecessors in 1893-4.

The session opened on November 13th, 1894, with the inaugural address of the President, Sir Robert Rawlinson, K.C.B., which, although it contained some valuable remarks upon questions of immediate interest, such as the water supply and main drainage of London, was, appropriately enough, to a great extent of a retrospective character, it being the last address that was delivered in the old building. A feature in connection with this meeting which will be pleasantly remembered by those who were present was the telling autobiographical sketch of his career given by the venerable President in replying to the customary vote of thanks.

During the session between November, 1894, and April, 1895, fourteen papers were read and discussed at length. These range over a large number of subjects, both of civil and mechanical engineering, the latter being perhaps the more numerous. Among the former, the group of papers on mountain railways, read in January last, is most prominent. This includes descriptions of the St. Gothard Tunnel approaches, and the Stanzer Horn Cable Railway, by Mr. S. J. Berg; the Monistrol and Montserrat Rack Railway, by Mr. A. Collett, both authors including a large amount of general information upon mountain lines in appendices; and the Usin Mountain Line in Japan, also on the rack system, by Mr. C. A. W. Pownall. The discussion and correspondence upon these papers was very voluminous, extending to nearly a hundred pages, which include a great deal of supplementary information upon other lines in other parts of the world. Among new engineering works, Mr. W. D. Bruce's paper on the Kidderpur Docks, in the Hooghley, below Calcutta, is perhaps the most interesting as describing an important harbour improvement carried out on ground of an extremely difficult character, as was evidenced by the movement of the walls during construction. The character of this accident, and the method adopted for repairing it, form the subjects of a supplemental paper by Mr. H. J. Apjohn, the resident engineer in charge of the works. The special difficulties of this class of work were abundantly evidenced in the discussion, which was one of the most instructive of the session.

The mechanical papers discussed were comparatively few in number, including a paper on "Boiler Explosions," by Mr. W. H. Fowler, which, although presented in an abridged form, gave a broad, general summary of the causes of steam boiler failures, and afforded the opportunity for a fairly good discussion. Mr. John Richardson's paper on the "Regulation of Steam Engines" gave a sketch of the development of the centrifugal regulator, from the original invention of James Watt down to the present time, and the further refinements to be obtained by combining electrical with mechanical regulation. Of greater interest, however, than either of the foregoing was the paper by Mr. H. Davey on "Steam Engine Economy," who considers that the efficiency of the Cornish engine has not been exceeded by any of the newer developments, and that the compound Cornish cycle, when coupled with a good feed-water heater, will be found to be from 8 to 10 per cent. more economical per actual horse-power than the triple-expansion engine. This view found support in the discussion from Mr. Robinson, who pointed out the essential similarity in principle between the Willans and the Cornish single-acting engines, in spite of their great difference of form.

Mining and metallurgical matters were represented by Messrs. Butters and Smart's paper on "Cyanide Extraction Plant," a useful description of the working of the MacArthur Forrest process in the Transvaal gold mines. Mr. E. B. Wain's, on "Colliery Surface Works," giving the details of the surface plant of a North Staffordshire colliery, which was followed by an extremely able discussion; and a pair of grouped papers on "Electrical Appliances in Mining;" one by Mr. R. Robertson describing the electrical underground haulage at Earnock Colliery; and the other, by Mr. Robert Hay, dealt with the problem of working a bucket dredger in a river channel by a mountain stream two miles away, which has been satisfactorily solved by the agency of a Pelton wheel driving two Brush Victoria dynamos, giving a current of 730 ampères at 1170 volts. This power is applied in lifting auriferous alluvium from the river bottom, which is then washed over blanket tables, the waste falling back into the river. The weekly return of gold is from 10 oz. to 70 oz. per week for a working cost of £85. The discussion on these papers showed a general tendency to favour the use of electricity in preference to other usual methods of haulage, and a point of interest was raised, but not settled, as to the mechanical efficiency of impact water wheels working under a very high head of water.

Naval matters were under consideration, both at the beginning and the ending of the session, in the papers by Mr. A. J. Durston on the "Machinery of Warships," and on "Torpedo Boat Destroyers," by Messrs. Thornycroft and Barnaby. The first of these—a review of the machinery fitted in the seventy ships built under the Naval Defence Act of 1889, with a large amount of detail in a statistical appendix—was instrumental in raising a long and well sustained discussion upon the numerous controversial points associated with the subject, such as design of framings, forced draught, water-tube boilers, &c., many of which appeared in an intensified form, with the addition of the question of vibration at high speeds in the discussion on the second paper. The last paper, in addition to numerous diagrams and models, was illustrated by a series of excellent lantern views from original photographs, which is noticeable as a departure from the former practice of the Institution in the matter of illustrations.

The second section of selected papers published without reading and discussion contains 47 contributions, ranging over a large number of subjects: hydraulic works in the different forms of river and sea improvements, docks and harbours, &c., being very fully represented. Among these some of the more important are Mr. O. Güttmann's paper on the "Removal of the Iron Gates on the Danube;" Mr. Kenny's on "Machinery for Sea Works," which covers similar ground to that of Mr. Walter Pitt, published in Vol. cxiii., but treats the subject from the point of view of the executive engineer rather than that of the machine designer, the experience recorded being that obtained in the construction of harbours in New Zealand; and Mr. Adam Scott's on the "Deep-water Quays at Newcastle-upon-Tyne." A complete account of the Tilbury Docks is supplied by Mr. T. F. Scott for the first time, the publication of the paper having been delayed pending the settlement of legal proceedings; and Professor Vernon Harcourt has compiled a series of brief notices of such important works as Portland Harbour, the Severn Tunnel, the Forth and Tower Bridges, and the Clyde and Tyne River Improvement Works, none of which have been completely described in the "Minutes of Proceedings." One of the most remarkable of the structural works described is the bridge over the Danube at Munderkingen, by Mr. C. A. Leibbrand, in which the link-bearing system of iron bridges is reproduced in a flat concrete arch of 164ft. span, and 13½ft. rise.

The papers on water supply and filtration are so numerous that we are unable to mention even a small proportion of them. Indian and Colonial undertakings are largely represented, and a melancholy interest attaches to one of them, that on "The Muggel Lake Filtration," as being a posthumous work of the late Mr. Henry Gill, who was so long and honourably associated with the Berlin water supply.

In mechanical subjects Mr. Archibald Sharp has continued his former study of circular forms of wheel teeth into a general memoir upon the subject, which is perhaps the most considerable analytical study presented; and the same position may be accorded on the experimental side to Mr. Bryan Donkin's "Experiments on Centrifugal Fans," which, being the last paper in vol. cxxii., may appropriately conclude our survey of the work of the session.

The James Forrest Lecture, by Prof. Unwin, on "The Experimental Study of Heat Engines," is so well known to most of our readers, that we record only the fact of its appearance in the proper place in the same volume.

Although the losses of the Institution by deaths and resignations have been unusually large—amounting to 170—the additions to the roll have been 325, so that the net increase was 155; the final numbers in all classes being 5921, as against 5766 in March, 1894. The associate class shows a slight diminution from 376 to 355, which may be expected to continue; the student class for the first time in several years shows a slight increase from 791 to 816 on the numbers in the preceding year. The financial position of the Institution still continues to be satisfactory, although it is not possible to give any very detailed comparison with the results of former years, owing to the disturbing element introduced by the new building operations, and which may probably be expected to influence the accounts for some years to come. We hope by the time our notice of the successors of these volumes becomes due, that the members may be comfortably housed in their new home. The editorial work continues to be done in the same excellent manner as before, leaving little to be desired in the way of improvement. We may, however, suggest—supposing it to be possible—that some restraint might be placed upon the exuberance of discussion by correspondence. The correspondents, unlike the author who is subjected to the referee, and the speakers in discussion who are controlled by the chair, the clock, and the patience of the audience, seem to enjoy complete liberty of space, which in some instances seems to be rather unmercifully exercised.

Besides the four columns of "Minutes of Proceedings," an important addition has been made during the year to the publications of the Institution in the second part of the subject index, containing an analysis of the contents of the sixty volumes that have appeared in the fifteen sessions, 1879-80 to 1893-94, both inclusive. The system followed is the same as that adopted in the first volume published in 1881, from which it differs principally in size, being about one-half larger, or 533 instead of 374 pages, and as each page contains about forty entries, the volume may be said to contain 20,000 or more references, or probably three or four to each title. Another improvement is the new library catalogue which has lately been completed, and steps are taken to keep it up by printing the titles of new additions every month. It will be necessary, however, to have the library arranged in its new quarters to fully realise the value of these alterations.

Plate Girder Railway Bridges. By MAURICE FITZMAURICE, B.A., B.E., M. Inst. C.E. London: E. and F. N. Spon, 125, Strand. 1895. 8vo.

As the title indicates, Mr. Fitzmaurice deals only with one class of girders, but this limitation has its value, in that he is able within the space of the 102 pages of his book to deal with them in such a way as to make the book of practical as well as theoretical value. Much of that part of the book which shows, by little other than simple arithmetic, the methods of arriving at the nature and value of the stresses in plate girders, is, of course, equally applicable to lattice girders, but the stresses in struts and ties of the latter are not touched upon, though the means of arriving at shearing stresses gives the student, in large part, a key to them. As well as the diagrams necessary to the elucidation of the simple formula used for bending, shearing, compression, and tension moments under dead and rolling loads, the author gives a series of engravings from drawings of actual girders, including transverse sections of plate girder bridges and floors, which will make the book useful, not only to the student, but more particularly to young engineers, and some of their elders, who are called upon to devote their attention to plate girder railway bridges.

A Treatise on Hydraulics. By HENRY T. BOVEY, M. Inst. C.E., LL.D., F.R.S.E. New York: John Wiley and Sons. London: Chapman and Hall. 8vo. 1895.

THIS is an eminently practical, albeit theoretical, book, and is evidently written by one who appreciates the points in hydraulics much as they would occur as questions in practice of an engineer. It is, of course, impossible to deal with in 332 pages at that length with which we are accustomed to find some questions treated in books on hydraulics, but the essential subjects are in general nevertheless most satisfactorily dealt with, and a large number of examples of an instructive kind are given at the end of each chapter. Some questions have recently arisen which make it doubtful whether the rate of discharge of water from a cylindrical tube horizontally projecting from a tank, varies precisely in proportion to the square root of the head in that tank, and it is questionable whether any very recent experiments have been made to redetermine the results obtained on this subject by Berneouille and others. Mr. Bovey deals with the flow through orifices and over weirs, through pipes and in open channels, with fluid friction, and with methods of gauging. A chapter on impact leads to the final chapter on hydraulic motors and centrifugal pumps, these two chapters occupying 147 pages, and into these the author has compressed the greater part of all that is essential on the theory of water wheels and turbines, including that very excellent and simple motor, the Pelton wheel. With regard to this latter, however, considering its practical importance, and the very high efficiency with which he credits it, it would have been better had he illustrated as well as described the form and section of the cups or buckets, to which that efficiency is ascribed in comparison with its predecessor, the "hurdy gurdy." Mr Bovey's book is one which may be highly recommended.

SHORT NOTICES.

International Railway Congress. Fifth Session. London: June-July. 1895. Summary of proceedings. Bruxelles, P. Weissenbruch, Imprimeur du Roi, 45, rue du Poincon, 45. 1895.—This summary will be found by many interested in railway matters a very useful index to the whole of the proceedings of last year's London Congress. The reports and discussions are given in abstract, but not illustrated. The Bulletin de la Commission Internationale du Congress des Chemins de fer, of which Nos. 10, 11, and 12 of vol. ix. have been issued in one part, will in future be printed entirely in English and separately in French, so English readers can have theirs complete in English only, thus occupying much less space.

The "Shipping World" Year Book. A desk manual on Trade, Commerce, and Navigation. Edited by Evan Rowland Jones. 1896. London: *Shipping World* Office. 1896.—This is the tenth issue of a very useful book. It is bulkier than its predecessors, but still very compendious. The "Tariffs of Foreign Countries" is a valuable compilation, and is corrected to December 15th last. We have tested the book in various ways, and have almost always found the information we sought. But we did not find anything about the regulations of the Royal Naval Reserve, nor the present rules for fixing light screens.

BOOKS RECEIVED.

Annual Report of the Commissioner of Patents for the Year 1894. Washington: Government Printing Office. 1895.

Index to the Literature of Didymium, 1842-1893. By A. C. Langmuir, Ph.D. City of Washington: The Smithsonian Institution. 1894.

Indexes to the Literatures of Cerium and Lanthanum. By W. H. Magee, Ph.D. City of Washington: The Smithsonian Institution. 1895.

The Exhibit of the Smithsonian Institution at the Cotton States Exposition, Atalanta, 1895. City of Washington: For distribution at the Exposition. 1895.

An Account of the Smithsonian Institution. Its Origin, History, Objects, and Achievements. City of Washington: For distribution at the Atalanta Exposition. 1895.

On the Densities of Oxygen and Hydrogen, and on the Ratio of their Atomic Weights. By Edward W. Morley, Ph.D. City of Washington: The Smithsonian Institution. 1895.

Cassell's History of England, from the Earliest Period to the Present Time. With original illustrations. Part I. To be completed in fifty-two weekly parts. London: Cassell and Company, Ld. Price 6d.

Notes on Permanent Way Material, Platelaying, and Points and Crossings, with a few Remarks on Signalling and Interlocking. By W. H. Cole, M. Inst. C.E. Second edition. London: E. and F. N. Spon. 1896.

Sell's Directory of Registered Telegraphic Addresses: National Directory of Large Commercial Houses, and Buyer's Guide. Published annually, with three quarterly editions. By Henry Sell. 1896. Prices, including supplements: Subscribers, 18s.; non-subscribers, 21s. London: Henry Sell.

DANIEL KINNEAR CLARK.

THE death of Mr. Daniel Kinnear Clark severs another of those links with the railways of the past now all too few. Albeit he never carried out any great engineering work, he was a noteworthy man, and will not soon be forgotten. He died at his residence, 8, Buckingham-street, Adelphi, on January 22nd, aged 74. Of his early years and parentage little is known. We first hear of him as an apprentice in the Phœnix Ironworks, Glasgow, then carried on by Messrs. Thomas Eddington and Sons. Subsequently he was an assistant to Mr. Miller, who had an extensive practice as a civil engineer in Edinburgh. Mr. Miller had a good deal to do with railways, and after young Clark had been with him for three years, he was appointed locomotive superintendent to the Great North of Scotland Railway. While there he was diligent in obtaining information on the performance of locomotives, consumption of fuel, train resistance, &c. For some reason, however, probably inherent in the man, he does not seem to have taken kindly to practical engineering. So long as experiments or investigations were to be carried out or conducted, he was happy; but the everyday routine duties of an engineer in a responsible position did not appear to suit him. He had a strong literary bent. In 1855 he published his book on the locomotive engine and the machinery of railways. Nothing so complete and altogether satisfactory had been published before; nothing equal to it has appeared since. Colburn's treatise, modelled on the same lines, never was completed by the author. To this moment Clark's book is a standard work of reference. Of course, the lapse of time has rendered much that it contains obsolete. Locomotives of much greater power than Clark dreamed of are running, but the fact remains that Clark made scarcely any mistakes. The most prominent is, perhaps, his statement concerning train resistante, and the formulæ for calculating it, namely:—Total resistance, including engine, $R = 8 + \frac{v^2}{171}$; resistance of train alone, $R^1 = 6 + \frac{v^2}{240}$, when v = speed in miles per hour. To apply this to a recent instance. For a speed of 73 miles an hour we have $R = 8 \frac{\cdot 73^2}{171} = 39$ lb. nearly per ton, instead of 15 lb., the American estimate. But before we condemn Clark it is well to remember that the modern road is very different from that on which he carried out his experiments. It is beyond doubt that the stiffness of the road is a measure of the resistance, and Clark's experiments were made on a weak track, and with rolling stock whose resistance was much greater than that of the modern long-bodied car. The resistance per ton of train diminishes rapidly with the dead weight of the vehicle, the bulk or air displacement remaining the same, and Clark had no opportunities for measuring resistance at high velocities.

The success of his book was so great that Mr. Clark left the Great North of Scotland Railway and started in business as a consulting engineer in London. In 1857 he established himself in 8, Buckingham-street, Adelphi, and there for forty years he lived and worked. Of how few can a similar story of long residence be told? The fact bears testimony to the remarkable adhesiveness of the man. He had no desire to wander; he did curiously little to bring himself into notice, and yet where is the engineer of the last generation who did not know D. K. Clark either personally or by reputation.

In 1861 it became necessary to appoint an engineer to take charge of the machinery department of the International Exhibition of 1862. The choice devolved on Mr. Clark, and he carried out the work and discharged the duties with a skill and tact and an absence of friction worthy of all praise. The putting in of the mains to supply steam to the machinery in motion was at that time a very difficult task. The mains were laid underground, and much skill and forethought had to be used to get rid of water, and avoid leakage due to unequal expansion and contraction, Even in the present day work of this kind is not always properly done. But Mr. Clark's work was quite satisfactory. His employment at the Exhibition just suited him, and he there conducted several experiments, the most noteworthy perhaps being a trial of centrifugal pumps. Then he wrote a book, "The Exhibited Machinery of 1862," which, if it did not add to his reputation, constituted a most useful volume for reference.

During the next few years we find him acting as judge for the Royal Agricultural Society, and carrying out experiments, almost always in connection with steam or fuel. In connection with the Smoke Abatement Exhibition at South Kensington in 1881, he conducted an elaborate series of experiments, and his treatise on the subject embodying the results of his experiments may be said to contain all that is known or worth knowing concerning the domestic consumption of fuel.

But before this, that is to say in 1877, he produced the book which will do more to keep his name alive than any other which he wrote; we refer to "A Manual of Rules, Tables, and Data for Mechanical Engineers." Those of our readers who do not possess this monumental volume of 984 pages could form no idea of what it is from a few lines of description here. Those who have it—and they include no doubt the great majority of mechanical engineers—know that there is no other work like it. Is it not a volume in which we can always find just the information sought. Of how many reference volumes can that be said? The work has gone through several editions. In 1878 he brought out a small volume on "Tramway Construction," subsequently much enlarged and improved, and in 1892 his work on "The Steam Engine and Boilers," which deserves to rank with the very best treatises ever written. This was the last work of any importance Mr. Clark accomplished. During the last few years his health has been gradually failing; of late years he lived a very retired life, and was seldom seen in public. He was a member of the Institution of Civil Engineers, joining that body as far back as 1854, and he contributed to it no fewer than eight papers, among which those on the "St. Gothard Tunnel," "Railway Locomotive Stock," and "The Evaporative Performance of Steam Boilers," deserve special mention.

A NEW MAP OF METROPOLITAN RAILWAYS, Tramways, and miscellaneous improvements deposited, at the Private Bill Office, November 30th, 1895, for session 1896, has been published by Edward Stanford, of London, as usual. The new tramways are, as in the past few years, very few and insignificant, except of the effect of the London County Council policy of preventing enterprise by trying to get everything into its hands for good or ill. The proposed railway work is also very small, and public works for London under private Bills of but scant importance.

LETTERS TO THE EDITOR.

We do not hold ourselves responsible for the opinions of our correspondents.)

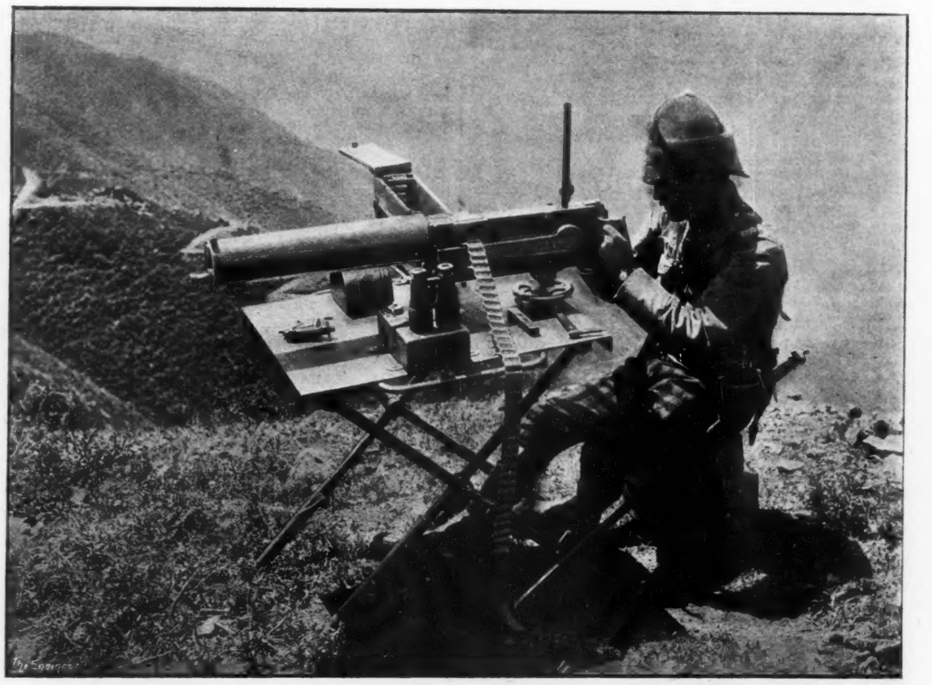
RAILWAY SHOPS IN WAR.

SIR,—The following extract from a letter I have received from my brother, who is superintendent of the locomotive department of the North-Western Railway at Rawul Pindi, may be of interest to your readers as showing the great assistance rendered to the military authorities by the railway shops, at a time when the work in transporting troops and camp followers assembling for the Chitral campaign was exceedingly heavy. He says:—

"I am sending you a ferrotype drawing and two photographs—taken by a sergeant of the Royal Engineers—of a table that I designed and made for the King's Own Scottish Borderers for their Maxim gun, as they could not take the regulation wheeled carriage up into Chitral. Lieutenant McAlister, who had charge of the Maxim gun, failing to get any kind of table made in the Rawul Pindi Arsenal, obtained permission from the General officer commanding the division to apply to me to help him. He brought the gun and carriage to my office at the North-Western Railway shops at 4 p.m. on March 18th, and explained that he wanted a table with hinged telescopic legs to take the pivot of the gun, traversing gear, &c., the weight not to exceed a mule's load—160 lb. After a brief consultation with Mr. T. O'Brien, the erecting-shop foreman, I made a rough sketch with a few principal dimensions, which Lieutenant A. accepted as embodying his ideas. We commenced work on the job on the morning of the 19th, and after three days the unfinished table was taken to the ranges and tried; but the elevating gear did not work satisfactorily. Lieutenant A. explained what was required, and the fault was rectified by the foreman at once. The drawing—which, however, was not made till some fourteen days later—shows fairly clearly all the different parts. The table was finished by 4 p.m. on March 24th, and so steady was it that at 700 yards they made 230 hits out of 250 shots on a target 6ft. square. It weighed complete 158 lb., and was approved by all who saw it. At the last moment we had also to make a special saddle to carry the table, as the mule greatly objected to carry it on the regulation Government saddle.

"Lieutenant McAlister wrote to me on June 8th saying, 'I must again thank you for all the trouble you took in thinking out the machine—table—which proved most successful, and which, in spite of your pessimistic views when comparing with the other'—I also made a tripod pivot for the Highlanders' Maxim gun—'has been held by the authorities to be infinitely superior. The great fault, of course, is its weight, and also its confined traversing gear.' You will understand the difficulties under which the table was made, when I tell you that the King's Own Scottish Borderers had to start on March 26th, and that at the time we were engaged in forwarding to the base at Nowshera 15,000 troops, 20,000 followers, 35,000 camels, horses, cattle, ponies, mules, and donkeys, not to mention several trains full of commissariat and transport stores, the regular daily service of two passenger trains each way being maintained throughout." I enclose the drawing and photographs.

Chatham, January 1st. R. M. H. BUCKLAND, Capt. R.E.



BUCKLAND'S MAXIM GUN TABLE

HORSELESS CARRIAGES.

SIR,—I have read with great interest the descriptions you have published from time to time of mechanically-propelled road carriages, and look forward to obtaining a great deal of information through the medium of your journal, which will, no doubt, be brought out in your proposed road carriage competition.

My object in writing to you is to ask you to be kind enough to put me in communication with inventors or builders of these carriages, as I believe there is a vast field for them here on our goldfields, where a large number of finds are scattered over an enormous area, in some cases 200 miles apart, and many of the roads are entirely dependent on condensers, at which water is sold at prices ranging from 3d. to 1s. per gallon.

Horses have been chiefly used up to the present, but owing to the cost of feed they are being replaced by camels, which, in my opinion, must give way to the motor carriage.

These carriages should be of very strong construction to stand the jolts and jars of travelling on bad roads, and special care should be taken to exclude dust, which is extremely fine, from bearings, &c. The workmanship should be good on account of the difficulty of effecting repairs, and the mechanism as simple as possible. INQUIRER.

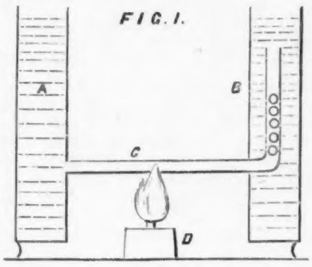
Western Australia.

[We shall have pleasure in forwarding to our correspondent any letters endorsed, "Horseless Carriages, Western Australia," which may be sent to our care.—ED. E.]

CIRCULATION IN WATER-TUBE BOILERS.

SIR,—M. Bellens' letter in THE ENGINEER of January 17th is another proof—not wanted, for the thing is certain—that there is no conformity of belief as to the way in which circulation is made to take place in a boiler. There are many theories and many theorists, and there is no agreement, for everyone claims that he only is right, and the rest are wrong. Now a great many persons have carried out experiments, more or less elaborate, with glass and other models, and the experiments made seem to have given different answers to the questions they were intended to settle. I myself have studied the subject for many years, and although I have succeeded in getting circulation in water-tube boilers to any desired extent, I am not ashamed to confess that I do not know with any certainty why circulation takes place. Neither, I am sure, does Mr. Yarrow, nor Mr. Thornycroft, nor M. Normand, nor M. Bellens. They believe they know, but I am certain they do not.

FIG. 1.



But I think I may say that I know what will not produce circulation. I have had so many disappointments, so many schemes perfect in theory, which failed utterly in practice, that on this point I can speak with a fair approach to conviction that I really know. It may be well to name one or two of these negatives.

In the first place, then, the theory that circulation takes place because there is steam and water in one leg of a U tube, and water only in the other, is not true. Your statement that the hydraulic head prevents circulation from that cause is perfectly correct. Some years ago I was engaged in carrying out an elaborate series of experiments, and the following, among others, is, I think, conclusive.

A and B are two flat vessels, united by a pipe not shown, and away from flame. C is a glass tube, bent up at one end as shown. The details of the apparatus and the method of putting it together are immaterial. When the water contained was made to boil, equality of temperature was obtained, and I assumed that I could use a horizontal tube at C, if only I got a fair start with bubbles in the bent-up leg B. Nothing of the kind. There was no certainty of circulation either way. When circulation was going on all right, it was only necessary to raise A ever so little to start the circulation the other way, and the water flowed down B instead of up it. Now, if the mere lightness of the contents of B as compared with A could cause circulation, why should inclining C the least trifle beat the ascending power in B? Precisely the same action took place in C that takes place in a spirit level, and no bubbles in B made any difference.

Now take another experiment, very easily carried out. M. Bellens' diagram will almost serve to show what I mean, but not quite. Put in water enough only just to fill the tube and a little over, as at A, and apply a lamp at B. Circulation will take place freely. Now let some water boil away. Still circulation will go on; but it will be seen that the down pipe is full of solid water, while the rising pipe is half bubbles. Now take away the lamp, and it will be seen that there is not water to fill the tube more than two-thirds full. It follows that the rising pipe contained as much steam as water, bulk for bulk. How did half a pound of water in C balance so nearly a pound of water in D? Obviously by the hydraulic head. Again, take the same general arrangements, but fit a stop cock at the lower bend of the tube. Let this be shut while action is going on, and then take away the lamp. D will be found full of water, or nearly so, and C half empty. Why? These two experiments can be varied, always with the same result, that we can get the down pipe quite full, while the rising pipe is half empty. And a further experiment, which it would take up too much space to detail, will show that water is not being delivered by the rising pipe at anything like the rate required to keep D full. Indeed, if we like we may partially plug D at the top, and still it will be found to be full when the stop cock is turned and the lamp removed.

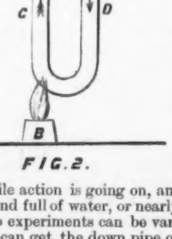


FIG. 2.

I have amply confirmed Mr. Yarrow's observations in that I know that the circulation in a water-tube boiler, however effective and even violent in appearance, is very easily overset. In a word, the force producing it is very small indeed, whatever that force is.

"THE ENGINEER."

SWAIN ENG.

I could say much more on this subject, but I think I have written enough for the moment. I see younger men going over ground that I have not only trodden, but sifted and searched. There are many puzzles in nature, but I know of none more perplexing than circulation in boilers and its causes. OLD TUBE.

Birkenhead, January 25th.

"THE ORIGIN AND RATIONALE OF COLLIERY EXPLOSIONS."

SIR,—The review upon my book bearing the above title in THE ENGINEER of the 27th ult. gives much ground for complaint, especially those parts which offer misleading and incorrect summaries of my views; and I am compelled to ask you for space to point out the misrepresentations.

The reviewer says:—"As far as we have been able to apprehend the author's views, they are to the effect that the primary cause of an explosion in a non-gaseous mine is the destructive distillation of a portion of the coal dust lying in the neighbourhood of a blown out shot." The accepted meaning of the technicality "a blown out shot" is that the products of the explosive are wholly expelled from the shot hole without rupturing the walls of the hole, or displacing any strata, and that the heat energy is wholly available for other purposes. The shot referred to in a non-gaseous mine in my book was not a "blown out shot." On page 13 it is recorded, "the hole was found fractured from end to end, with the excavated *débris* lying underneath." Only a portion of the heat energy was, therefore, available, and it is correctly described on page 68: "The unexpended heat in the charge of mining powder was projected into the small coal and coal dust on the floor in the vicinity of the shot, and instituted distillatory action.

The reviewer proceeds:—"It is also advanced that lack of oxygen is the usual reason for those blanks in the explosion which are its most curious feature, and that similar breaks may be caused by the dampness of a part of the workings through which the transmission of the explosion might occur under less favourable conditions." The phrase "Blanks in the explosion" does not convey what the book says. On page 13 the words are:—"The field of disaster presented the phenomena of numerous disturbances in falls of roof, shattered doors, and broken trams, at widely distant points; but the spaces that intervened between these disruptions betrayed no evidence of violent forces—the timber, trams, and loose materials they contained, were neither displaced nor damaged." These disturbances are subsequently examined in detail, and shown to have been caused by local subsidiary explosions, and to have occurred where the normal volumes of air were largely increased—see pages 108-113. The statement that "dampness" may cause "similar breaks" has no foundation. At page 129 I have shown that dampness will not arrest the propagation of an explosion or cause a gap in the explosive phenomena.

Again, the reviewer says:—"The first statement, viz., that hydrogen is the chief agent in the explosion [this phrase is not in the book, nor is it warranted] is supported by the fact that carbon, both as coked residues and as finely divided smoke, *i.e.*, lamp-black, is found on examining the scene of an explosion, and, further, that there is evidence of the substantial absence of the most characteristic product—often combustion of carbon—viz., carbon dioxide. But surely all this may be true without imagining the previous liberation of hydrogen by destructive distillation or the dissociation of hydrocarbons, upon which the author insists." The fallacy of this argument is in the reviewer's partial statement of the phenomena which the book records. The coked residues are unquestionably produced by the destructive distillation of coal. The deposits of impalpable carbon—diamond-black, see page 58, not lamp-black, as the reviewer states—could only have been produced by the oxidation of the hydrogen constituent of some of the educts of the coal in the first place, and subsequently by dissociation at the elevated temperature that would then be present—see pages 56, 57, and 63—as no other source existed. My words on page 57 are:—"The educts could only have obtained limited supplies of oxygen—sufficient to oxidise the hydrogen constituent of a portion of the gaseous hydrocarbons. This oxidation of hydrogen would generate large quantities of heat, and necessarily produce the observed elevation of temperature. In the process of the oxidation of the hydrogen the carbon constituent could not be converted into carbon dioxide, because there was no oxygen for that purpose, therefore it was unchanged, and deposited in the condition in which it was found, and the temperature due to the oxidation of hydrogen being considerably higher than the temperatures of dissociation of gaseous hydrocarbons, the remaining portion of these gases would be decomposed, yielding further quantities of carbon."

Carbon dioxide was not appreciably present in the gaseous products that filled the mine after the disaster. The reviewer omits and ignores the important phenomenon of the disaster, viz., the exhibitions of explosive violence, and thus shows the fallacy of his argument. He suggests that the partial phenomena he quotes from the book has its illustration in the preparation of lamp-black, saying—"No one who has seen the flame of a pan of dead oil burning at the entrance of a set of lamp-black chambers, and yielding crude finely divided carbon in rich abundance, could doubt this possibility—the tendency to oxidation of hydrogen rather than carbon, in limited quantities of air—and it is indisputable that the same preferential oxidation will take place with any fuel containing carbon and hydrogen. An appreciation of this fact saves the necessity for constructing any special theory to account for the presence of coked and carbonised residues after the occurrence of an explosion."

I have shown at pages 52, 53, and 54 that there was no such flame as that arising from burning "dead oil," or in the combustion of gaseous hydrocarbons, at Timsbury Colliery. It is well known that no explosive violence is exerted in burning hydrocarbons distilled from coal, when the hydrogen only is oxidised and the carbon is separated out in solid form. It is superfluous to add that, after the oxidation of the hydrogen constituent, there can be no explosion from the residual or resultant gas. The principal phenomena of colliery explosions, viz., the exhibitions of explosive violence, therefore remain inexplicable upon the reviewer's hypothesis, and he should have observed on page 54 the following words, "The combustion of gaseous hydrocarbons at the locus, and at the moment of their evolution, exerts no more mechanical force than is exhibited in a burning gas jet; consequently the isolated and widely-separated exhibitions of violence over the field of the disaster would be as inexplicable upon such an hypothesis as they are inconsistent with it. The disconnected exhibitions of violence are facts of observation, and an adequate cause for them must find a place in the *rationale* of the explosion." Whatever the processes were which yielded the finely-divided carbon, they must have also brought about the accumulation of successive bodies of an explosive gas, which, by its explosive combustion, could produce violent effects and yield no carbon-dioxide gas, and the theory I have advanced above accounts for these phenomena.

The reviewer continues:—"It is likely enough that the author is correct in supposing the arrest of an explosion is often due to a local defect of oxygen; but even when this idea is accepted fully it is not easy to see how the explosion can begin again at a further point without leaving marked evidence of action between each adjacent pair of points. If it be assumed that the gases remaining after the first explosion contain enough combustible matter, or can generate enough combustible matter by their supposed distillatory action on the coal dust, to prove again explosive when a fresh supply of oxygen is reached, it is still far from clear how the heat required to raise the explosive mixture at the far and distant point to the initial temperature of explosion can be transmitted from the first to the second explosive centre without seriously burning all intermediate objects."

It is difficult to understand what the reviewer means by his assumption of gases remaining after the first explosion containing combustible matter, or that they can generate enough combustible matter by their supposed distillatory action on coal dust. He should know that the principal agent immediately arising in the first explosion is the heat due to the oxidation of the hydrogen, and ought to have seen on page 63 that "the propagation of No. 1 explosion presents no difficulty, as it is only necessary to recall the series of chemical actions that produced the initial explosion to recognise the fact that No. 2 explosion would be brought about by a repetition of this series of actions; and when it is known that the heat that originated the disaster at the shot represents that due to the oxidation of less than four grammes of hydrogen, and that the 500 cubic feet suggested to have been ignited in No. 1 explosion would generate more than three hundred times that quantity, an idea will be gained of the enormous resources of heat that were now available for re-instituting the activities and propagating the explosion through the mine."

The difficulty the reviewer chiefly expresses, however, is, in a word, his desire for evidence of "burning" upon all intermediate objects between the explosions. He should have read the following on pages 108-109:—"The spaces between the propagated explosions, though free from explosive violence, exhibited the effects due to immense thermal changes, the ordinary temperature being from 20 deg. C. to 25 deg. C., while the educts of the coal were raised to the heat due to the partial combustion that was constantly going on, representing a temperature of over 2000 deg. C. The educts at this exalted temperature were travelling through the passages, heating the strata upon which they were impinged; but were immediately followed by gases at the ordinary temperature, which were loaded with the condensed water due to the oxidation of the hydrogen. The old method of breaking the strata by heating with fire and cooling with water was therefore in operation, though for a comparatively momentary period, but sufficient to bring about disintegration of loose strata and scaling of faces of stone to which timber was wedged." The book also records that bodies of victims found in the spaces between the explosions were badly burnt, and the walls of the passages were covered, and the stagnant gases between the disturbances were laden with the flocculent carbon, which indicated the temperature of burning hydrogen, and showed the unbroken presence of gases at an exalted temperature from one explosion to the other.

I have now shown the reviewer's imperfect acquaintance with my book, and the inaccuracy of the statements he makes purporting to be taken from the book. It is not surprising that a work which involved an immense amount of labour and research should not be understood upon the superficial and fragmentary perusal which the reviewer appears to have given to it; but when, with a synopsis of each chapter and an index at his disposal, he says, "In it data and deductions, facts and hypotheses, are mingled inextricably, and in places it is with the utmost difficulty that the line of argument can be followed," he makes a statement that is opposed by over a dozen technical reviewers who have carefully read the book, and for which there is absolutely no foundation.

Bristol, January 21st. DONALD M. D. STUART.

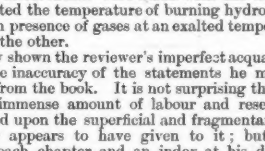
[We have broken through our rules by publishing Mr. Stuart's letter, simply because we desire to avoid the smallest cause of suspicion that he has not had fair play; but we must add that on matters of opinion, our reviewer is at least as competent an authority as Mr. Stuart.—ED. E.]

SLIDE VALVE FRICTION.

SIR,—Referring to the letter from Mr. Edward I. M. Davies on the above subject, in your issue of the 10th inst., I was pleased to see the question discussed, and with your permission will give the results of some experiments I have made.

Mr. Davies gives a case from actual practice, taking a constant pressure on the back of the slide valve of $9\frac{1}{4}$in. × 17in. × 140 lb. steam pressure = 22,015 lb.; here I think he makes a mistake. I would take the pressure at the position the valve stands at ($5\frac{1}{4}$in. × 15in. + $1\frac{1}{4}$in. × 15in.) × 140 lb. = 13,650 lb. The reason for this I will show.

FIG. 1



If Mr. Davies makes an experiment, takes a flat plate lying on a flat face representing a cylinder face and slide valve but no ports, when a pressure of steam is turned on to the back of the valve, the valve will require just the same pull on the valve spindle to move it as when the steam is shut off. Next drill a hole A in cylinder face one square inch area, turn a pressure of 140 lb. steam on, and the pull on the valve spindle will be increased by $\frac{140}{8} = 17\frac{1}{2}$ lb. I have also found by experiment that the coefficient of friction for a slide valve moistened by steam is one-eighth. Next take the flat plate off, and put the slide valve on to face, turn 140 lb. pressure on, and the pull on valve spindle will be increased to $\frac{5\frac{1}{4} \times 15 \times 140}{8} = 1378{\cdot}125$ lb.

FIG. 2

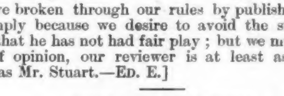


FIG. 3

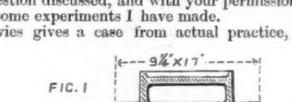

When the valve travels to near the centre, the area of the ports A and C will require to be added to area of port in slide valve, $(1\frac{1}{4} + 1\frac{1}{4} + 5\frac{1}{4}) \times 15$in., to get total pressure on slide valve. The back pressure in ports in A, B, C can then be deducted.

I have also found by experiment that if the ports are not altered, the surface of slide valve may be increased without adding to the friction. For instance, if the above shown slide valve were made 19in. wide, instead of 17in. wide, the pull on valve spindle would not be increased. The experiments can be made on a reduced scale. If Mr. Davies or anyone else should try this, I will be pleased to hear if the results agree with mine, as in any text-book I have seen the pressure on back of slide valve is given = total area of valve, minus area of port in valve, multiplied by pressure of steam, the writers, perhaps, thinking it was too trifling a point to trouble much about; but I see it is a point of interest to many.

NAVAL ENGINEERS.

SIR,—As the time is approaching when the Admiralty will expect to receive entries for the examination admitting to the Royal Naval Engineering College, Keyham, perhaps you will permit me space to direct attention to the value which "My Lords" attach to the training which they provide.

Lean's Navy List, p. 44A, is as follows:—Harding, *Loveridge*, Butland, Maxwell, Stokes, Stocker, Magrath, *Wallace*, *Gordon*, Kelly, Steil, Roberton, *Durston*, *Cleave*, Ware, Smith, Page, Hall, Charlton, Stocker, Thompson, Soper, Hare. All the foregoing are dated July 1st, 1894—probationary—but those whose names are in italics do not appear to have attended the Royal Naval Engineering College, and yet they are placed before the last nine who have been trained at Keyham and Greenwich. What examination have the five passed which places them before those who have been trained under their lordships' direction?

Again, six assistant-engineers for temporary service are entered for July 2nd, 1894, apparently one day junior to those trained in the Royal Naval Engineering College, but seeing that they are appointed and date from July 2nd, 1894, whereas the Keyham students are entered as probationary, and judging from past experience, will only date from confirmation, *i.e.*, July 1st, 1895, the temporary service men will be one year senior. From this it would seem that the smaller the training the better for the position, and avoid going to the Royal Naval College, Greenwich. The arrangement may be perfectly satisfactory to individuals, but is not calculated to encourage capable men to join the service, and is likely to lead to disaster if pursued. CIVILIAN.

January 18th.

THE TEMPER OF HANDSAWS.

SIR,—Will any of your Sheffield readers tell me why it is that handsaws in most cases lose their stiffness and elasticity after about a year's work? Now and again we come across a saw which is good to the last inch, but very rarely. The saws are not overheated, they are not subject to blows, but they become soft, and bend on the least provocation. One man in this shop says that it is caused by the vibration due to filing, and that if the saw is properly blocked while being filed it will not soften. Another theory is that they are only hard planished, and that the least loss of skin will leave them soft, just as a watch mainspring is useless if the blue is taken off. If any reader can help to a solution, I shall be obliged. PATTERN MAKER.

Birmingham, Jan. 30th.

THE LINDE PROCESS.

SIR,—The article in your last number clears up the points on which I was in doubt. Of course, so soon as it is clear that the so-called Joule's effect is not needed, all the rest is plain sailing.

It may be well to say a word here concerning a mistake which I have often heard made concerning refrigerating machines. It is that energy is got out of air in the cooler. So it is, but not more than has been put into it by the compressing pump. This will be made clear by remembering that the energy in a given weight of air is measured by its temperature, and by nothing else. The total energy in a pound of air isothermally compressed is just the same after compression as before, provided the temperature is the same, but its available energy may be greater. The available energy, however, is quite a different thing from the total energy.

Woodstock, January 28th. M. A.

EARLY LOCOMOTIVES.

SIR,—Your correspondent who writes under the name of "G. A. Sekon" is certainly most indefatigable in his attempts to silence every one who differs from himself. He also shows a most remarkable propensity for twisting about the statements made by his antagonists to suit his own ends. Mr. Sekon either fails to understand, or he will not understand, that those who differ from him have been all along writing about early Great Western engines—engines which actually ran on wheels and did work, not about designs and theories, and steamboats on wheels, nor even about special contrivances rigged up for special purposes.

In the first place, even if we admit, for the sake of argument, that such an engine as that shown in Mr. Wilson's drawing ever existed, it has yet to be proved that it was built for and delivered to the Great Western Railway. The quotations with which your correspondent favours us cannot be urged as evidence of this. It does not in the very least follow that if such experiments as are referred to took place, the engines used necessarily belonged to the Great Western Railway. In the next place, I wish to draw attention to a point which is entirely ignored by Mr. Sekon: even if it be admitted that the engines used in such experiments actually did belong to the Great Western Railway, it does not follow that they were built in the form of steamboats. I have seen many engines with snow ploughs attached in front, but no one would on that account, in describing these engines, describe them as "being fitted at the leading end with a contrivance specially designed for the purpose of removing snow." It no more follows that an air-cutting apparatus of the form shown could be considered as part of the engine than a snow plough or the indicator and necessary appendages used in taking diagrams would be so considered. Such adjuncts are attached when required, either for practical or experimental purposes, and are removed when the purpose for which they were required is accomplished. If it were necessary our engines would be fitted with snow ploughs all the year round; it is not necessary, therefore they are only so fitted at certain seasons. The arrangement shown could be attached as easily as a snow plough. Mr. Sekon's argument, therefore, falls to the ground.

I note that Mr. Sekon has been in communication with a gentleman who is unable to remember anything. This is most instructive. The evidence of one who does not remember anything is certainly of most unquestionable value.

It is a very remarkable circumstance that Mr. Wilson should write to Mr. Sekon as to the drawing which appeared in THE ENGINEER of 3rd inst. Why does he not write to THE ENGINEER and tell us all he knows? We want to know whence he got his drawing, and we also require all the other information he can give us if he wishes to prove his contention. This drawing has been referred to by Mr. Sekon as an authentic drawing. Its authenticity has yet to be proved. As the matter now stands, the drawing is of no value whatever as evidence.

Can Mr. Sekon explain how it is that the Great Western Railway Company sent drawings of every class of engine which had run on their rails to the Chicago Exhibition, and stated that they never had more than one 10ft. wheel engine, if they really had more than one? And why is it that the company have no drawings of the remarkable engines Mr. Sekon contends for, seeing that they have drawings of all their engines? I have asked Mr. Sekon to explain this before, but he has never done so.

Dundee, January 25th. D. H. LITTLEJOHN.

SIR,—My statement that "no engine was ever built for the Great Western Railway with a projector" is perfectly true, and in accordance with the information possessed by the company. Mr. G. A. Sekon should know that when Dr. Lardner made some experiments upon the subject of air resistance, he had a temporary projecting wind-cutting device constructed, but it formed no part of the engine, and was simply attached to the fronts of the engines by bolts. The device was tried on several engines; for instance, North Star, Vulcan, Lion, Ajax, and Hurricane. In view of these facts, most certainly I do not "withdraw" any statement which I have made.

Mr. Sekon tell us he has communicated with a gentleman who is "unable to remember;" surely that is of little importance, and the fact that Mr. Sekon has had a private letter from Mr. Wilson does not throw light on the matter. What is required is a reply from Mr. Wilson himself to the questions I have asked in your columns. Of course the Grasshopper had 10ft. wheels, as it was but the third name of the Hurricane. Mr. Acworth in his "Railways of England," page 254, makes this quite clear. "Mr. Dean," he tells us, gives "the true explanation of the third alias of the Hurricane, namely, that it was a shed nickname." I have in my possession the complete list of every early engine which ever ran on the Great Western rails, and can tell Mr. Sekon that there was not one named Grasshopper, and the company gave this information to the authorities of the Chicago Exhibition.

Leicester, January 27th. CLEMENT E. STRETTON.

SIR,—The engines fitted with "cut airs" referred to by Dr. Lardner were in every respect ordinary locomotives, such as have been illustrated over and over again. They were fitted with conical fronts or bows made of deal boards, and for the purpose of experiment were run with and without them alternately. An account of these experiments will be found in Dr. Lardner's "Treatise on the Steam Engine." My edition is dated 1856. Mr. Sekon has interpreted Dr. Lardner erroneously. J. W.

Gorton, January 28th.

SIR,—Mr. Sekon's letter in last week's issue compels me again to point out that the Ajax was not of the construction Mr. Wilson's sketch shows. A true drawing of this engine was given by Mr. C. E. Stretton some months back, and on this drawing being shown to an engineman who had been on this engine it was at once pronounced correct. The wheel was spokeless, 8ft. in diameter, and the framing the same as the Premier.

If Mr. Sekon means, when he says the Ajax had a 10ft. driving wheel, the nickname of Hurricane, I quite agree with him, except that this engine, sometimes called the Grasshopper, did not have a boiler plate disc wheel, but an ordinary spoked 10ft. wheel, and that it was made at Messrs. R. and W. Hawthorn's, Newcastle-on-Tyne, to the designs of Mr. T. E. Harrison—an illustration of which is given in the "Locomotive and its Development," by Mr. C. E. Stretton. Did not Mr. Dean tell Mr. W. M. Ackworth that the Grasshopper and the Hurricane were one and the same locomotive? HENRY GREENLY.

36, Third-avenue, London, W.,
January 27th.

[We can insert no further references to 10ft. driving wheels—the Grasshopper, Ajax, or Hurricane.—ED. E.]

A CENTURY OF "SOHO."

A HUNDRED years ago, January 30th, 1796, there was a famous celebration of a memorable incident in the history of the far-famed Soho Works. In 1766 the place was rapidly increasing under the untiring management of Matthew Boulton, and very soon after the fame of Soho was known the wide world over. Celebrities of all sorts rushed to see the famous works and to purchase the dainty "toys" which had won fame in every part of Europe, and had made "Brummagem" the "toyshop of Europe." Boswell and Johnson gave their praise, and repeated Boulton's famous phrase, that he "sold what all the world wants—Power." His rare energy, intelligence, and skill, his undaunted perseverance, his appreciation of his famous colleagues—Watt, Murdock, and many others—rapidly raised the Soho Works to unrivalled fame. Year after year the western slopes from the Handsworth-road to Hockley Brook were covered with new buildings, filled with new machinery, and were pouring forth tons of fabrics, from huge steam engines down to sword-hilts, shoe-buckles, ladies' nick-nacks, silver and plated wares, which were previously unknown, and have never been surpassed. The tide of fame flowed on for many years, and in 1796 a large "annex" was built for the use and work of the larger machinery and manufactures.

About a mile from "The Soho" a vast area was prepared for the engineering productions of James Watt and the workpeople of the time. "The Soho Foundry" was completed in 1796, and on January 30th a famous "rearing feast" the full details of which have been preserved—was generously provided, and was served in the most "classic" style. "The first fruits of the cultivated land at Soho were sacrificed at the Altar of Vulcan, and eaten by the Cyclops in the great Hall of the Temple, which (was) 46ft. wide and 100ft. long;" and, after a generous dinner and a good band of martial music, "the Founder of Soho entered, and consecrated this new branch of it by sprinkling the walls with wine, and then, in the name of Vulcan and all the Gods and Goddesses of Fire and Water, pronounced the name of it 'Soho Foundry,' and all the people cried 'Amen.'" A benediction was then "pronounced on the undertaking, and a thanksgiving offered for the protection and preservation of the lives and limbs of the workmen during the erection;" and Mr. Boulton gave his benediction, "May this establishment be ever prosperous, may no misfortune ever happen to it, may it give birth to many useful arts and inventions, may it prove beneficial to all mankind, and yield comfort and happiness to all who may be employed in it."

In 1850-1851 the inevitable changes of fortune and fame led to the dismantling of the Soho, and the rare and useful tools and products were sold; but some of the more modern and useful order were removed to the Soho Foundry. Here they remained for many years, partly in continuing the coinage of the bronze pence for the Mint, and partly in the large machinery which could be used for great sea-going steamers and other large orders. During some years there had been many competitions in engineering works, and the orders and improvements declined till, in 1895, when the Soho Foundry, and all its machinery—the work of many of the most famous "fathers of Soho"—came to the hammer of the auctioneer, and have now been scattered far and wide. Only one consolation remains: That the memories of the "heroes of Soho," Boulton, Watt, Murdock, Creighton, Buckle, Keir, Southern, Wright, Harden, Barnsley, Hamilton, Jas. Watt, jun., and Blake will ever have the *aere perennius* of print in the records of the rare energy and engineering skill so deservedly honoured during a hundred years. Another consolation remains, that the records of Soho Foundry—1765-1850—have fortunately been saved from loss or damage, and that they have been carefully preserved by a generous neighbour of the Soho Foundry, and will hereafter, when fully examined, reveal and record a mass of facts of the famous Soho heroes and their work, which are of priceless value in the history of engineering and scientific skill. Exit Soho—Resurget.—*Birmingham Post.*

SUSPENDED SAFETY LIFT

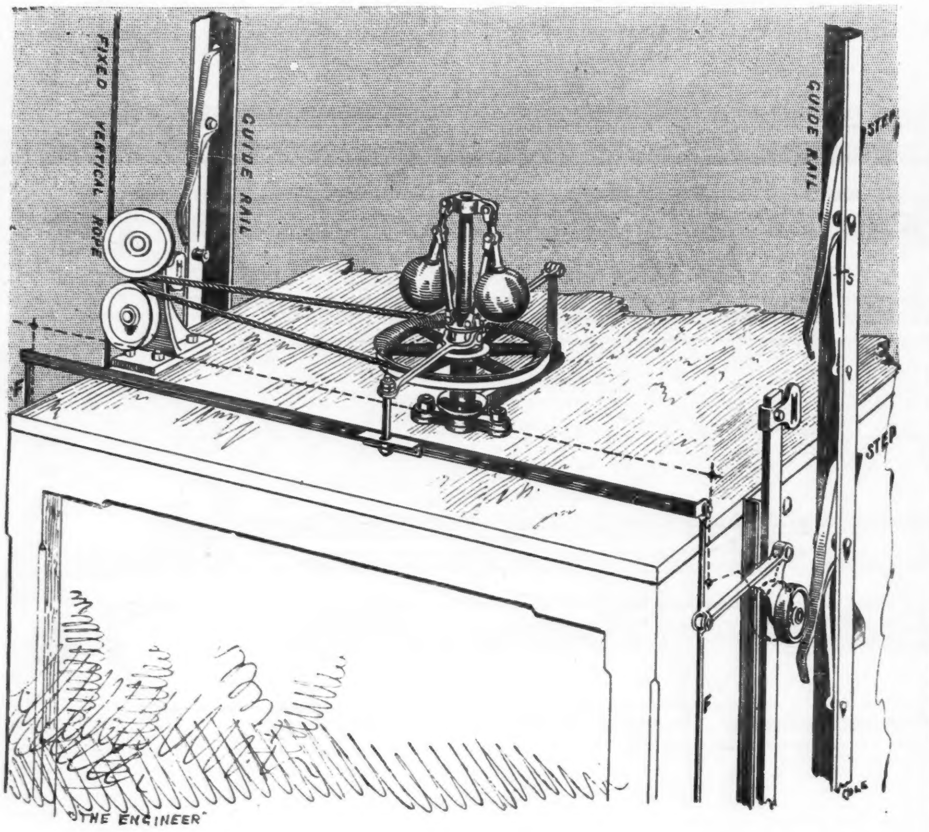
SUSPENDED SAFETY LIFT

MESSRS. J. AND H. BROOKES, CAPE WORKS, SMETHWICK, ENGINEERS

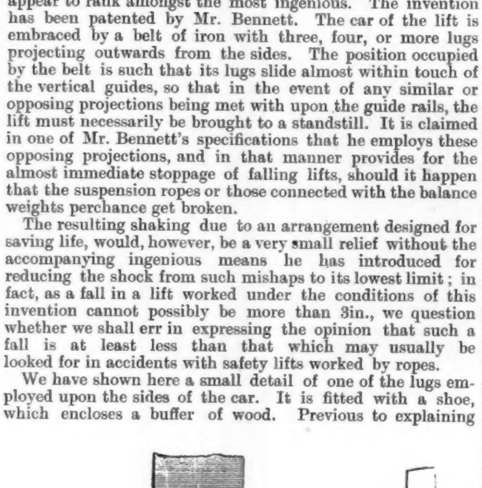


THE EUREKA SUSPENDED LIFT.

AMONG the several inventions introduced for the prevention of accidents in suspended lifts, those which form the subject of our present notice, illustrated above and on page 121, appear to rank amongst the most ingenious. The invention has been patented by Mr. Bennett. The car of the lift is embraced by a belt of iron with three, four, or more lugs projecting outwards from the sides. The position occupied by the belt is such that its lugs slide almost within touch of the vertical guides, so that in the event of any similar or opposing projections being met with upon the guide rails, the lift must necessarily be brought to a standstill. It is claimed in one of Mr. Bennett's specifications that he employs these opposing projections, and in that manner provides for the almost immediate stoppage of falling lifts, should it happen that the suspension ropes or those connected with the balance weights perchance get broken.

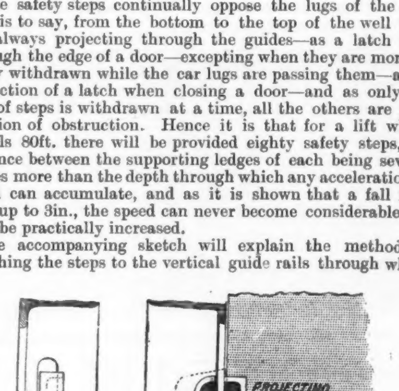
The resulting shaking due to an arrangement designed for saving life, would, however, be a very small relief without the accompanying ingenious means he has introduced for reducing the shock from such mishaps to its lowest limit; in fact, as a fall in a lift worked under the conditions of this invention cannot possibly be more than 3in., we question whether we shall err in expressing the opinion that such a fall is at least less than that which may usually be looked for in accidents with safety lifts worked by ropes.

We have shown here a small detail of one of the lugs employed upon the sides of the car. It is fitted with a shoe, which encloses a buffer of wood. Previous to explaining the arrangement adopted for removing the opposing projections so that the others may pass, it will be necessary to explain, in conjunction with a former paragraph, the reason why an accidental fall of a lift under these conditions will be confined to a maximum distance of 3in. The opposing projections or "steps," as they may now be called, occur at distances not exceeding 2ft. throughout the entire height of the lift space, and on the opposite side of the well they are situated at intermediate distances, so that by their alternate levels the actual space between the safety ledges is the same as if the full complement had been fixed at a pitch of 12in. on one guide rail. Still further to reduce the fall of a car in case of accident, it is arranged that in all passenger lifts at least four lugs, as shown at A, B, and C, Figs. 1, 3, and 4, are provided, and these are timed to engage the steps at different intervals, thus further reducing the maximum possible fall of 3in., while it is probable that the actual drop may be considerably less.



The safety steps continually oppose the lugs of the car, that is to say, from the bottom to the top of the well they are always projecting through the guides—as a latch does through the edge of a door—excepting when they are momentarily withdrawn while the car lugs are passing them—as in the action of a latch when closing a door—and as only one pair of steps is withdrawn at a time, all the others are in a position of obstruction. Hence it is that for a lift which travels 80ft. there will be provided eighty safety steps, the distance between the supporting ledges of each being several inches more than the depth through which any acceleration of speed can accumulate, and as it is shown that a fall may vary up to 3in., the speed can never become considerable nor even be practically increased.

The accompanying sketch will explain the method of attaching the steps to the vertical guide rails through which they project, and thereby become, when in their normal position, the obstructions already referred to.



In our illustration, Fig. 1 shows that step No. 4 is withdrawn when the lug B is passing it, while steps 3 and 5 at the same moment are in the position of obstruction, should the suspension gear give way, and in the same figure the relative positions of the lug A and the step No. 3 will explain that if the car fell when it was in the position shown in the illustration, its descent would not exceed 3in., whereas if fracture occurred when step No. 3 was withdrawn, No. 4 would be projecting, and the fall might be as much as 20in. This, however, is only applicable in cases where the steps are 2ft. apart, and when the safety of the hoist depended upon step No. 4 alone. But owing to the special arrangement already described, since the steps are placed alternately, and the lugs A, B, and C are also timed for different intervals, there would always be several lugs—in passenger lifts at least seven—each of them nearer than step No. 3 is to the lug A, and the nearer the opposing projections approach each other so much the less will be the fall.

The preceding sketch of one of the steps, shows its position in dotted lines when withdrawn, due to its contact with the trip gear which is carried on the car, and represented in side elevation in Fig. 1. A bar D on the side of the car carries four sets of trip gear; there are duplicate sets upon the opposite side differently timed, the drawings of which will be found explanatory. It will be noted that the pitch of the gear centres does not correspond with that of the steps, it being essential, as previously explained, that only one pair should be tripped at a time; thus, if we consider the car to be in the act of descending in Fig. 1, step No. 4 shows that it has already been tripped to make way for passing the lug B, whilst No. 3 is in contact with its gear and is just about to be withdrawn, but will not clear the lug A until No. 4 projects. At the same time step No. 5 is in obstruction, and thus protection is provided for throughout.

It will now be understood that as long as the bar D and its four sets of trip gear bear the same relative position with the steps as they now occupy—and they will remain so as long as the suspension gear is in proper condition—see Figs. 1 and 3—they will upset the steps whenever the car lugs A, B, and C are approaching; but should the bar D be raised so as to allow the opposing projections to meet each other before the trip rollers arrive at the striking point, the car will consequently be caused to stop.

Figs. 3 and 4 are perspective views illustrating the latter alternative, and also indicating how the bar D is controlled by the suspension beams, which in Figs. 1, 2, and 3 are seen in their ordinary working position, and in Fig. 4 that of having been upset.

In the case of the breakage of suspension ropes, as assumed in Fig. 4, the counterbalance weights assert their power, and haul up the outer ends of the beams, and as these are interlocked with the side bars D, the latter are simultaneously carried up with the beams, and the trip gear becomes inoperative as is shown; the supposition being that the suspension gear gave way when the car was in the position indicated in Fig, 3, and as the trip gear was not in time to withdraw the step No. 3, it remained in the position for obstructing the car, and stopped it at the lug A.

As it has now been explained that safety is assured by causing delay in the arrival of the trip gear at the tipping lever of the steps, Mr. Bennett has devised other means whereby the trip gear may be bodily lifted away from the steps by the use of a governor which is carried on the top of the car. Further reference to Fig. 1 will show that by raising the rod F with which the four sets of trip motion are coupled, their rollers will be moved into the positions shown by dotted lines, without interfering with the bar D.

We give an illustration showing how the governor will act, and in order to avoid confusion of parts, besides assisting our explanation, we have preferred separating this arrangement from those previously described. It is frequently the case that lifts are overloaded, and it is with a view to arrest any undue speed arising from this cause that the services of a governor are enlisted for causing the trip motion to become inoperative.

A vertical rope which is fixed in the well is traversed by guide pulleys, leading it to and from the motion pulley of the governor, and our drawing, which shows a perspective view of the general arrangement, will explain the simple and effectual way in which the safety steps are prevented from avoiding the passage of the car by the elevation of the coupling rods F.

We have now considered the case of the breakage of suspension ropes, with the result that a falling car must inevitably rest upon the inactive steps, and we have also shown how, in a similar manner, overloading can be counteracted. The governing apparatus, however, supplies a further safeguard; in the event of both suspension and counter-balance ropes parting at the same time, the suspension beams would fail to lift the bars D, and the steps would still be upset as the car descended; but, as the governor acts at the slightest sign of acceleration in the speed of the lift, the steps are not tripped, and the car rests upon the first step it would otherwise have passed.

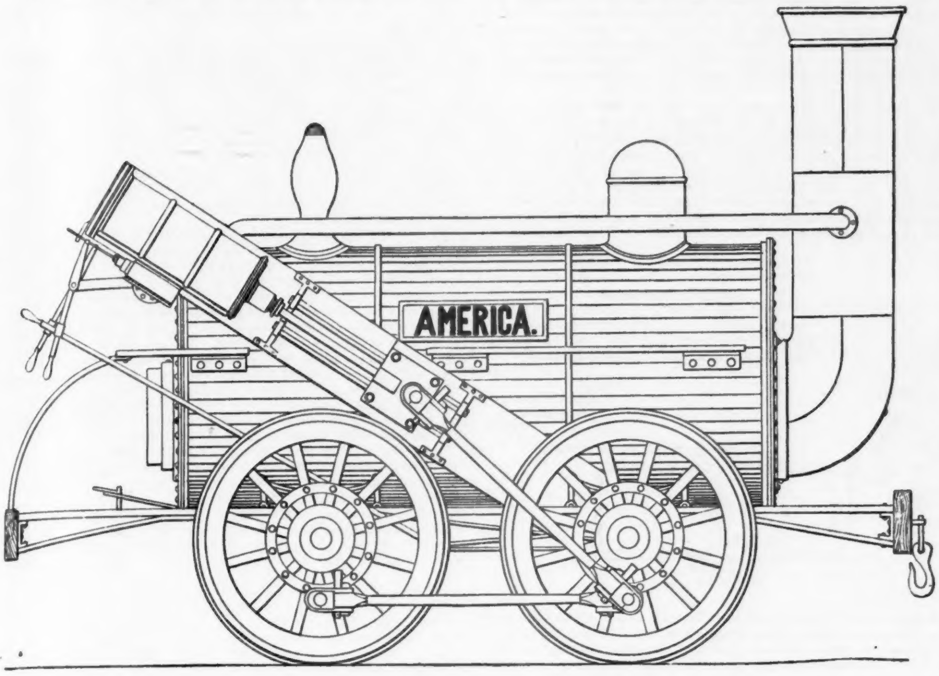
Most of our readers can doubtless recall instances when, owing to misadventure, men have stood within the area of descending lifts, very frequently paying for it with their lives. A screen E—Figs. 1 and 2—is hinged underneath and at the back part of the car, leaving its front edge hanging loosely, with freedom to move upwards, but normally lying at an incline, similarly to that shown in Fig. 1. At both of its front corners it is in touch with pins V on the coupling rods F, so that in the event of the front edge meeting with an obstruction the rods F are pushed upwards, communicating to the trip gear the same moment, with a like result as when actuated by an increased speed of the governor.

There are two excellent examples of these lifts constructed by Messrs. J. and H. Brookes, of Smethwick, running in Birmingham, one having been in continual work for four years, and we have carefully inspected a large working model with very satisfactory results.

TRADE AND BUSINESS ANNOUNCEMENTS. — Messrs. Samuel Denison and Sons, of Old Grammar School Foundry, Leeds, have established a London office at 7, Billister-buildings, 49, Leadenhall-street, E.C.

DEATH OF MR. THOMAS HOWARD, C.E.—The death is announced of Mr. Thomas Howard, C.E., at the advanced age of eighty. Mr. Howard, who had for some time past resided at Netherleigh, in the Shrubbery, Weston-super-Mare, was in 1855 appointed the first docks engineer under the Bristol Corporation. The *Bristol Mercury* says:—"He filled the office with benefit to the city and distinction to himself until November, 1882, when he resigned after a period of honourable service extending over twenty-seven years. Early in his career he made elaborate surveys and plans in connection with the dockisation of the river. It was Mr. Howard, indeed, who first conceived the bold idea of that project, to which he devoted many years' labour. Mr. Howard was directly concerned with the works of river improvement which were carried on under the Bristol Docks Act of 1865, and also designed and made the fine new lock at Cumberland Basin, and the new junction lock with the harbour, and also the pontoon. Other special works executed in Mr. Howard's period of office were the Harbour Railway Wharf, the deepening of the harbour and construction of the quay wall at Mardyke, and the reconstruction of Bath Bridge, after the wrought iron structure was smashed by a barge in 'the fifties.' Mr. Howard's reputation will be always sustained by the voluminous and clear reports which he has left as records of all the engineering points connected not only with the Docks Estate, but with every branch of Corporation work."

THE FIRST LOCOMOTIVE IN THE UNITED STATES



THE FIRST LOCOMOTIVE IN THE UNITED STATES.

The books and records of the Delaware and Hudson Canal Company show that early in the year 1828, having heard of the success of the Stockton and Darlington Railway, it was resolved to send Mr. Horatio Allen to England with instructions to obtain information and purchase rails and four locomotives. There is a report made by Mr. Allen, in which he gives details of English railways, and informs the company that he has given an order for three engines to Foster, Rastrick and Co., of Stourbridge, and has just given an order to Mr. Stephenson for one. This report was written in 1828, at Newcastle-upon-Tyne.

Stephenson's engine was named America; it was built in 1828, and arrived in New York, on board the ship Columbia, about the middle of January, 1829, and the "bill of lading" still exists, and was at the Chicago Exhibition.

The official diagram shows that the America ran on four wheels, had an iron bar framing and inclined cylinders, and was No. 12 in the books of Stephenson and Co.:—

	ft. in.
Diameter of boiler	4 1
Length of boiler	9 6
Dimensions of fire-place	4ft. by 3ft.
Diameter of cylinders	0 9
Length of stroke	2 0
Size of chimney	1 8
Size of feed-pump	0 1¼
Length of pump stroke	2 0
Wheels, diameter (wood)	4 0
Number of wheels	Four.
Angle of cylinders to the horizontal	33 deg.
Size of fire-tubes	1 7
Number of fire-tubes	Two.
Tubes were straight.	

Although Stephenson's engine America was undoubtedly the first railroad locomotive to *arrive* in the United States, it was *not* the first to be used.

The first part of the Delaware and Hudson Canal Company's railroad was not ready till 9th August, 1829, and on that day the Stourbridge Lion was worked by Mr. Allen, that engine having arrived in New York, in May, 1829, or about four months *after* the America. The America was a sister engine to the Lancaster Witch, of 1828, and was very like the Invicta, with the position of the cylinders reversed.

TRACTION ENGINE WHEELS.

On Thursday week, at the Glossop County Sessions, Messrs. William Preston and John Mason, trading as Preston and Mason, bleachers, Charlesworth, were summoned by Herbert Turley Chapman, surveyor of highways, Chapel-en-le-Frith, on behalf of the Derbyshire County Council, with being the owners of a certain locomotive on the Glossop and Marple Bridge main road, on December 17th, the driving wheels of which were not in accordance with the Act of Parliament. Other charges were preferred, embracing December 18th, 19th, and 21st. Mr. N. J. Hughes-Hallett, clerk to the Derbyshire County Council, appeared in support of the prosecution, and Mr. J. W. Tweedale defended, and pleaded not guilty to all five charges.

Mr. Hughes-Hallett, in opening the case, said the summonses were taken out formally in the name of Mr. Chapman, who was the main road surveyor for the district named, and the charge against the defendants was for a breach of the Act of Parliament, the Highways and Locomotives Amendment Act, 1878. The Act provided that the wheels of these locomotives shall be cylindrical and smooth-soled, or shod with diagonal cross-bars not less than 3in. in width, and not more than ¾in. in thickness. In the event of a breach of this Act of Parliament, a person was liable to a penalty not exceeding £5. It appeared that Messrs. Preston and Mason were the owners of two traction engines, one of which was already licensed to run in this county, and the other was not. On December 19th last he received an application, dated the 18th, from Messrs. Preston and Mason for a licence in respect to the engine that was the subject of the present charge. In accordance with the requirements of the County Council, a form had to be filled up, but it was not properly filled up; he returned it for further information, and he found that the wheels of the traction engine were not in accordance with the Act of Parliament, and he therefore drew defendants' attention to the fact. It was, however, not a question of the bye-laws, but the Act of Parliament; and therefore the licence was refused. It appeared that before making application for this licence, namely, on the 17th, the first day for which the summons was taken out, the defendants had used this engine, with the wheels not in accordance with the Act. He thought it was only right to say that he did not propose to do anything in the way of complaining against defendants for not having a licence, for at that time they enclosed a cheque for £10 which was required for it, but it was for not having the wheels of the engine in accordance with the Act of Parliament. On the first day mentioned a roadman in the employ of the County Council saw this engine running, and knowing that it had not been previously licensed he stopped the driver and made inquiries, and drew attention to the fact that the wheels were not the same as on the other engine, but although this fact was brought before defendants, the engine continued running for the four following days. The wheels of the engine, instead of being in accordance with the Act of Parliament, were made with what was known as "Boulton's studs," and the driving wheels of the engine, instead of having diagonal cross-bars, had studs 6in. square projecting 2in. from the surface of the wheels, and being 2in. apart. These studs are wood enclosed in iron ¾in. thick. These wheels, as a matter of fact—it was not a mere technical error on the part of the defendants—did considerable damage to the roads, and the County Council was bound to take proceedings in that matter, even apart from the question of the Act of Parliament. It might be pointed out for the defence that these wheels were in use in other districts. The Act, however, said that certain wheels shall be used, and to use a common expression, "Two blacks do not make one white." If other authorities did not enforce the law, that was no reason why the Derbyshire County Council should not enforce it.

Samuel Turner, roadman, in the employ of the County Council, gave evidence as to seeing the engine used with the wheels complained of.

By the Chairman: These blocks on the wheels in his opinion made bigger holes in the ground than the cross-bars.

Herbert Turley Chapman, surveyor of highways, Chapel-en-le-Frith, spoke to the damage done to the roads by the wheels. He held that on an ordinary macadamised road the present wheels complained of did considerably more damage than the ordinary cross-bars. In soft weather the springs did not give, but sunk in the road, making holes in which the water congregated.

The Chairman — Captain Partington — remarked that these engines were bound to be used largely in the future, and in his opinion this Boulton wheel had been devised to save the roads, and it did seem hard that this firm should be proceeded against when they had obtained the wheels with this intention.

Mr. Hughes-Hallett replied that the county authorities took a different view of the matter in regard to the roads.

Mr. Tweedale, replying for the defence, submitted that of all the miserable, petty cases ever brought before a Court of Justice this must strike them as being the very worst. What his clients had done in the matter had been done with perfect *bonâ fides*. The first day mentioned in the charges was the 17th December. On the 16th December his clients wrote to Mr. Hughes-Hallett, and sent a cheque for £10, asking for the usual licence for this particular engine, which, as they had heard, had on Boulton's patent wheels. In reply, Mr. Hughes-Hallett acknowledged the cheque, but wanted more particulars filling up. That was complied with, and everything that possibly could be done by his clients was done in the way of filling up the particulars. On the 23rd December, Mr. Hughes-Hallett wrote again to his clients, returning the cheque for £10, having found that the wheels were not in accordance with the Act of Parliament, and he refused the licence. He might point out that on the 19th December Mr. Hughes-Hallett returned the application, and wanted the answers completed, and in the meantime, having retained the cheque, his—Mr. Tweedale's—clients used the engine. After the 23rd December, when the letter came and the cheque was returned, refusing the licence, the engine was not used again. He thought if that first case had not been taken against defendants some time ago, the present case would not have been heard of. He characterised it as "persecution" rather than a "prosecution."

Mr. Hughes-Hallett—interrupting—objected to the expression, and said these cases had been taken all over the county. It was a breach of the bye-laws, and that the case had been taken through spite was absolutely untrue.

Mr. Tweedale said the whole thing was of such a trivial nature. He thought when his clients ceased to use the engine, that should have been enough for the County Council, instead of bringing everybody to Court that day to take part in such a case as the present one. He would place an expert in the box to prove that these Boulton wheels were the very best known, and did macadamised roads the least damage of any known. He would call the borough surveyor from Ashton-under-Lyne. In that borough a fee of 5s. was charged for traction engines passing through, but special facilities were given to those with Boulton's wheels, and no fee was charged. It was quite clear, whether there was a technical offence or not, that his clients had done everything they could in the matter.

Mr. J. T. Earnshaw, borough surveyor, Ashton-under-Lyne, which position it was stated he had occupied eighteen years, said he had had experience of traction engines ever since 1879, and traction engines passed through the borough of Ashton every day. Messrs. Gartside had an engine that passed through twice each day on its journey from Carrbrook to Manchester and back. In Ashton they made a special allowance to those people who used Boulton's wheels. Other engines that had not these wheels were charged 5s. for coming through. In his opinion Boulton's wheels did considerably less damage to the roads than those prescribed by Act of Parliament. He considered that if it had to be passed now the present Act of Parliament would not be framed in its present form. With regard to macadam roads, the engine wheels prescribed by Act of Parliament would damage the roads worse than the wheels now complained of. There was a greater surface of wheel on the road by using Messrs. Boulton's wheels.

Cross-examined by Mr. Hughes-Hallett, witness admitted that there were few macadamised roads at Ashton. He had, however, noticed the effect of the engines on macadamised roads. The cross-bar wheel was one that bore the whole of the weight, whereas the springs on the Boulton wheel would give under weight, and present more of a flat surface to the road. Mr. Hughes-Hallett contended that it was not a question of expert evidence—he could have brought expert evidence—but it was a question of the breach of the Act of Parliament.

The magistrates retired, along with the clerk, and on returning into Court, Captain Partington said they had discussed the matter, and they had to admit that defendants had broken the law, but they believed had broken it unknowingly. Defendants had made a very good effort to get a better wheel than the Act of Parliament described. The magistrates had decided to fine defendants 1s. in each case, with Court costs. The bench also thought that this matter should be represented to the authorities at Derby, and pointed out that the defendants had been making, and were making an effort, and that they had got a better wheel than the one mentioned in the Act of Parliament. The authorities ought to consider whether the defendants should be put to further trouble.

Mr. Hughes-Hallett said he would take care that the matter should be brought before his committee, which met the following day.

Mr. Tweedale said he had been informed since coming into court that notice was given in the House of Commons with regard to this section, and it was going to be brought forward in the next session of Parliament, to repeal it.

Mr. Boulton, whose patent was referred to in the case, was present in Court during the proceedings.—*Buxton Chronicle.*

TESTS TO SHOW THE DISTRIBUTION OF MOISTURE IN STEAM WHEN FLOWING THROUGH A HORIZONTAL PIPE.*

By D. S. Jacobus, Hoboken, N.J.

In a previous paper preliminary tests were presented which were made in connection with an investigation undertaken for the Babcock and Wilcox Company by Professor Denton.† In this paper it was demonstrated that various calorimeter nozzles, such as are now used in practice, do not give an average sample of the steam flowing though the steam main. It was also stated that tests were in progress to determine the efficiency of a nozzle devised by Professor Denton, which consists of a ½in. tube open at the end, passing through a stuffing-box, and so arranged that it may be moved to any position across the pipe under a full head of steam.

The tests made with the tube passing through a stuffing-box indicated that a greater part of the moisture was near the bottom of a horizontal pipe, and that it probably ran along in a small stream. If this was true, then an opening in the bottom of the pipe, so arranged that the water could run freely into it, would glean off all, or the greater part, of the moisture. The tests which are the subject of this paper were made to determine to what extent such an action takes place, and are a continuation of the preliminary investigation above referred to.

It was found that after steam had passed through 8ft. of horizontal 3in. pipe, 95 per cent. of the entrained moisture, or over, could be drawn from a ½in. pipe leading from the bottom of the 3in. pipe, for quantities of moisture as high as 8 per cent., and velocities as high as 25ft. per second.

The moisture was thoroughly mingled with the steam before entering the 3in. pipe. The apparatus was so arranged that the greater part of the moisture was initially near the top of the pipe, so that it had to fall through the steam during the time taken to travel over the space of 8ft. The theoretical time required for a body falling freely in space to travel from the top to the bottom of the pipe is about ⅛ of a second. Hence, the maximum initial horizontal velocity that such a body could have and reach the bottom in a horizontal space of 8ft. would be 64ft. per second.

It appears from the experiments, therefore, that for the particular set of conditions which existed, 95 per cent of the moisture can be gleaned from the bottom of a pipe, if the velocity of the steam is ⅜ that corresponding to the theoretical velocity already mentioned. For a velocity of 20ft. per second, or about ⅓ the theoretical velocity, 98 per cent. of the moisture was drawn from the bottom of the pipe for quantities of moisture as high as 10 per cent. For a velocity of 43ft. per second, or $\frac{7}{10}$ of the theoretical velocity, about 60 per cent. of the total moisture was drawn from the bottom of the pipe, and at half of the theoretical velocity about 90 per cent. was drawn out.

It cannot be said that these ratios will apply to all cases, and for this reason additional tests are to be made to determine the effect of increasing the length of the horizontal pipe.

A special series of experiments was made, in which a horizontal plate was placed about ¾in. above the bottom of the 3in. pipe, and over the ½in. pipe leading to the calorimeter. The plate was arranged so that all the moisture which collected under it would run into the calorimeter. The object of introducing the plate was to collect all the water which was near the bottom of the pipe, so as to determine to what extent a nozzle, simply tapped into the bottom of the pipe, would remove such moisture. The results of corresponding tests, with and without the plate over the calorimeter nozzle, are about the same, which indicate that a nozzle connected so that its inner end is flush, or slightly below the bottom of the pipe, will remove practically all the moisture which flows near the bottom of the pipe.

The results of the experiments on the 3in. pipe are given in detail in Table I.

In Professor Denton's experiments a single calorimeter was at first attached to the bottom of a horizontal 12in. pipe by means of a nozzle, which could be raised and lowered so as to draw steam from various sections of the pipe, as has been already described. It was found that the weight of moisture ranged between about 5 and 50 per cent. of the weight of steam passing through the calorimeter when the nozzle was lowered so as to be near the bottom of the pipe; whereas, when the nozzle was raised so as to be about 1¾in. above the bottom of the pipe, the steam which passed through the calorimeter was practically dry. In these tests the steam passed from the boiler through about 10ft. of horizontal 12in. pipe to an elbow, and thence through a second horizontal 12in. pipe. The calorimeter was attached to the second horizontal pipe about 6ft. from the elbow. The velocity of the steam was about 17ft. per second, representing about 500-horse power.

After making the tests with a single calorimeter, a second series of tests was made with two calorimeters, to determine if the moisture was all at the bottom, or if it was also creeping along the sides of the pipe. To make these tests the second calorimeter was placed at the same cross-section of the pipe as the first, but it was moved to one side, so as to be 4in. from the calorimeter attached directly to the bottom of the pipe. It was found that when both nozzles were set so that the ends were flush with the inner surface of the pipe, the calorimeter at the bottom of the pipe indicated

excessive moisture, whereas the calorimeter 4in. from it toward the side of the pipe showed practically dry steam. This indicated that all the moisture was at the bottom of the pipe.

The general arrangement of apparatus for conducting the tests on the 3in. horizontal pipe is represented in Fig. 1.

Superheated steam entered at A, and passed through a 3in. pipe surrounding a cooling pipe B. The cooling water entered at C and passed off at G. After passing the cooling pipe the steam passed through a device at D, which thoroughly mixed the steam with the water. This consisted of two plates placed about 1in. apart, in which were two holes about ⅝in. in diameter. The hole in the first plate encountered by the steam was at the bottom of the pipe, so that all moisture in the steam would be drawn from the bottom of the pipe. The steam and moisture then passed upward between the plates and out of the hole in the second plate. The hole in the second plate was placed near the top, so as to introduce the steam and moisture near the top of the 3in. pipe E. The calorimeter was attached at V. K is the separator portion of the calorimeter, and L the heat gauge. The temperature and pressure of the steam was measured on leaving the pipe E by means of the thermometer H, and the pressure gauge J. The thermometer H, was placed in a mercury well having an enlargement at its lower end and a thin neck. The steam was throttled by means of the valve M, from a pressure of about 80 lb. above the atmosphere in the pipe E, to about the pressure of the atmosphere in the 12in. drum N. The temperature of the steam after throttling was measured by a thermometer Q, placed in a mercury well, and by a thermometer P, which came in direct contact with the steam. The pressure in the drum N was measured by means of a mercury gauge. The steam flowing into the drum N was led to a surface condenser, and finally weighed.

FIG. 1.

The amount of moisture in the steam passing through the valve M was indicated by the amount of superheating in the 12in. drum N. This moisture, added to the moisture in the steam entering the Barrus calorimeter, gave the total moisture contained in the steam passing through the 3in. pipe. Corrections, determined directly by experiment, were made for all radiation. The factor of 0·48, for the specific heat of steam, was employed in calculating the percentage of moisture, and special experiments were made to show how nearly this method would agree, in the case of the 12in. drum, with the experimental normal reading for dry steam. These experiments, from the nature of the apparatus, could be made only with steam just at the point of superheating or with slightly superheated steam, and the results obtained were the same as in similar tests made on a Barrus calorimeter, and given in the paper on "Errors of Calorimeters."

TABLE I.

Percentage of Total Moisture Entering a 3in. Horizontal Steam Pipe that is Removed by a ½in. Drip Pipe.

The moisture in each case was either thoroughly mingled with the steam, or the greater part of it was near the top of the 3in. pipe at a point 8ft. distant from the ½in. drip pipe. Much of the moisture had, therefore, to fall through a distance nearly equal to the diameter of the 3in. pipe before it was drawn out at the ½in. drip pipe.

Conditions under which the tests were made.	Number of test.	Velocity of steam in 3in. pipe in feet per second.	Percentage of priming in steam passing thro' 3in. pipe.		Percentage of total moisture removed by the ½in. drip pipe leading to the Barrus calorimeter.
			Before reaching drip pipe.	After passing drip pipe*

	43	20·2	4·9	0·0	100·0

* The percentages of priming given in this column are calculated from the superheating in the 12in. drum, and are correct to within about $\frac{1}{10}$ per cent. The minus values are either accidental discrepancies, or they are caused by the fact that the steam was initially superheated, and tended to retain the property of producing a slightly higher "normal reading" than that given by the theoretical formula.

It was found that the experimental normal reading for steam in a maximum state of dryness, when corrections were made for all radiation, and the temperatures were corrected so as to correspond to those registered by an air thermometer, was 3 deg. higher than the theoretical normal reading.

The initial pressure in all the tests was about 80 lb. per square inch above the atmosphere. With steam that was slowly condensing the tests made in connection with the "Errors of Calorimeters" showed that the normal reading with a Barrus calorimeter was 3 deg. lower than for steam of the maximum dryness, so that if this same difference applies to the 12in. drum, the experimental normal reading for steam which is slowly condensing, and therefore contains the maximum amount of moisture, would be the same as the theoretical normal reading, employing a factor of 0·48 for the specific heat of steam.

Three series of tests were made. In the first there was no mixing device placed at D. In these it was found that the thermometer H would indicate superheating with considerable moisture entering the calorimeter nozzle V. The second series of tests were made after adding the mixing device D. In the third series of tests the 3in. pipe containing the cooling pipe B was lowered, together with the mixing device D, and the steam was made to pass through an S-shaped connection of 3in. pipe into the pipe E. This caused the steam which was admitted to E to pass upward through a vertical pipe, then turn through an elbow into the pipe E. The object of the latter arrangement was to make the mixture of steam and water enter the pipe E at the same velocity at which it flowed through the pipe E. When the steam and moisture entered the 3in. pipe directly from a ⅞in. hole in the mixing device D, it was initially at a much greater velocity than the average velocity in the pipe E, but it was considered best to make tests in this way so as to have one set of tests in which the conditions were as severe as possible.

An appendix is added. which gives the calculation of one of the tests in detail, together with the results of experiments to determine the radiation, and the details of the tests made to obtain the normal reading of the 12in. drum.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

AN average attendance of members was on 'Change to-day. Enquiries for steam coal continue good, and prices are firm at last week's quotations. Stems are generally well filled, and both docks are well occupied with tonnage. A slight decrease has taken place in the price of pitwood. Due to arrive in two or three weeks' time is the large steamer Algoa, to load her first cargo of about 13,000 tons of coal. This will be the largest vessel which has ever visited the port, or even the Bristol Channel. The s.s. Maroa broke the record last year with a cargo of 10,000 tons; the Algoa, as will be observed, will take away 3000 tons more than her. The Samoa, another big steamer, is also stemmed to load here shortly. The agents for both boats are Messrs. R. Gething and Co. A greater activity has taken place in the ship-repairing trade during the week than was the case the previous one.

Prices ruling on 'Change to-day were as follows:—Coal: Best steam, 8s. 6d. to 9s.; seconds, 8s. to 8s. 3d.; best house coal, 10s. 6d.; dock screenings, 5s. to 5s. 6d.; colliery small, 4s. 6d. to 5s.; smiths' coal, 6s. 6d.; patent fuel, 10s. 6d. Pig iron: Scotch warrants, 46s. 8d.; hematite warrants, 48s., f.o.b. Cumberland; Middlesbrough, No. 3, 37s. 10d. prompt; Middlesbrough hematite, 45s. 10d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails: Heavy sections, £4 10s.; light ditto, £5 to £5 10s., f.o.t. Tin-plate bars, £3 17s. 6d.; Siemens tin-plate bars, best, £4; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s. to 9s. 3d.; Siemens (coke finish), 9s. 6d.; Ternes, per double box, 28 by 20 C, 21s. to 22s. Pitwood, 15s. 6d. to 15s. 9d. London Exchange telegram: Copper £43 7s. 6d.; Straits tin, £60 7s. 6d.; freights continue firm.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE Midland Iron and Steel Wages Board met at Dudley, on Monday, to receive the accountant's certificate for November and December. It showed the net average selling price to be £5 15s. 3d. per ton. This compares with £5 12s. 7d. for September and October, or an improvement of 2s. 8d. per ton, and with £5 14s. 4d. for November and December of 1894. The average is reckoned on the selling rates of bars, hoops, sheets, plates, and strips, and regulates wages in Staffordshire and the Midlands, and also at a number of works affiliated to the Board, which are located in Lancashire, Yorkshire, and Wales.

The rise in the average occasioned much satisfaction on 'Change this—Thursday—afternoon, and was commented upon as a further satisfactory indication of the trade recovery which marked the latter portion of the year. The interruption occasioned by the foreign political disturbances has, it is pleasing to know, been succeeded by a resumption of the revival. Sheets, however, are the department in which prices mostly lag. Galvanised corrugated sheets are quoted this week a minimum of £10 5s. in bundles, but the more general figure is £10 10s. f.o.b. Black sheets are still quoted on the open market £7 2s. 6d. to £7 5s. for doubles, but the price is just now hardly more than a nominal one, and sales were reported to-day at £7 and occasionally under. Lattens were 15s. per ton additional upon doubles, whilst singles were in some cases as low as £6 15s. to £6 17s. 6d. per ton. Soft sheets for bucket making and working-up purposes were 2s. 6d. per ton over the price of hard sheets. Trunk sheets remain at £8 to £8 2s. 6d. for 24 w.g., with a good sale, and 7s. 6d. on for steel material, and deep stamping sheets of steel were £9 10s. to £10 10s. for doubles and trebles respectively.

Sales of steel to the sheet-rolling firms, in the form of tin bars, and billets, and slabs, are steadily increasing, and these descriptions are being rolled down to an augmented extent into steel sheets, to take the place of the sheets of iron hitherto chiefly employed. Steel all round was active, and prices were quoted £4 5s. to £4 10s. for Bessemer blooms, and billets, and tin bars, though some consumers declared themselves still able to place orders at £4 2s. 6d. —a figure which was generally considered to be exceptional. Imported steel angles and boiler plates were quoted £5 10s. to £5 17s. 6d.; sheets, £7 5s. to £7 10s.; and bars, £5 15s. to £6. Basic steel girders and angles were £5 5s. to £5 10s., and boiler plates £6 5s. per ton.

Pig iron sellers again reported increased business to-day, both in Staffordshire and Midland sorts, buyers being desirous of anticipating the market, lest it should go against them. Prices are decidedly stronger. All mine hot-air Staffordshire pigs are quoted 55s. to 57s. 6d.; part mines, 40s. to 42s. 6d.; and cinder sorts, 36s. to 37s. per ton. Northampton forge iron is quoted 41s. to 41s. 6d., and Derbyshire 42s. to 43s.; with sales taking place at 1s. per ton under these figures. Lincolns are 44s. 7d. per ton net.

The building of a line past the rapids and across the Shiré Highlands in Africa is greatly to be desired in the interest of the Protectorate, as a better means of communication and transport would give a great impetus to the development of the coffee plantations, which already produce some of the finest coffee that is placed on the London market, and are capable of almost indefinite extension. Should the projected line through Portuguese East Africa from the Ruo to Quillimane be seriously undertaken by the Zambesi Company, British Central Africa would practically be in direct railway connection with the East Coast, as the building of a section between Chimor and the termination of the Portuguese line would present no difficulties.

A reconstruction scheme is to be submitted to the shareholders of the Metropolitan Carriage and Wagon Co. on the 3rd of February. Particulars are given in a circular issued this week and signed by the board's chairman, from which it would seem that the conversion is more a matter of convenience than necessity. Apparently no anxiety need be entertained regarding it. A sum of £300,000 of authorised capital in excess of present requirements now stands upon the books. To get rid of the crushing liability of £5 per share on this amount, and to release as an asset a large and valuable freehold building estate, which at present is practically unrealisable, it is proposed to sell the business to a new company registered in the same name, but with more modern memorandum and articles of association. The new capital would be £150,000, divided into 30,000 shares of £5 each, fully paid.

Local engineering firms interested in the light railways movement are discussing this week information from Belgium regarding the light railways so extensively in operation there, which seems to suggest that more difficulties would probably be found in carrying out the system in our own country. It is stated that the primary conditions in England and Belgium are entirely different. Flanders is absolutely flat, densely peopled, occupied entirely by small owners who are able to cultivate their small holdings, of very light sandy soil, with little comparative labour and difficulty. Then, these lines run alongside the roads, without fence or protection of any kind. It seems risky to run trains at twelve or sixteen miles an hour under these conditions; but accidents very rarely happen. These lines have no works, bridges, fences, cuttings, stations, or signals. Their cost to make must be very slight, and their cost to maintain equally so.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—A generally steady business was reported on the Manchester Iron Exchange on Tuesday, with makers' prices very firm, both for raw and manufactured material. In pig iron, although the buying was not perhaps quite so large as last week, when some fairly heavy transactions were put through, there was quite as much inquiry as makers cared to entertain, and in some instances they were so heavily sold as to be practically out of the market. Here and there underselling on the part of speculative merchants is reported, but much more would seem to be made of this than is actually warranted, and certainly in the present condition of the market, anything like "bear" operations would be exceedingly risky. Lancashire makers are booking orders freely at their full list rates, which remain firm at 46s., less 2½, as the minimum for No. 3 foundry, delivered equal to Manchester. In district brands, one or two Lincolnshire makers are practically declining to book further orders, either in forge or foundry qualities, and there is some talk of a general advance in the arranged prices at a meeting to be held at the close of the present week. Already there is some hardening up, and delivered equal to Manchester, quotations for Lincolnshire now range from 41s. 6d. and 42s. for forge, to 43s. 6d. and 44s. 6d. for foundry, whilst Derbyshire foundry, which is also stronger, averages 46s. to 47s. net cash, delivered here. The current market quotations for outside brands offering here are much the same as last week. Middlesbrough is perhaps a trifle firmer, makers not quoting anything under 46s. 4d. net cash for good named foundry brands, whilst it would be difficult to buy ordinary brands, even through second hands, at much under 45s. 10d. delivered Manchester. For Scotch iron, prices are maintained, but there are a few cheap parcels in the market, and Eglinton might be brought at about 47s. 3d. to 47s. 6d. delivered Lancashire ports, and about 49s. 6d. delivered dock quays, Manchester—where a gradually increasing proportion of the business in this immediate district is now being put through—and Glengarnock about 1s. over the above figures.

No really material change can be noticed in the finished iron trade, except that makers report a better tone generally. Bars continue in active demand, and with makers books well filled prices are very firm at £5 10s. for Lancashire to £5 10s. and £5 15s. for North Staffordshire bars; sheets remain at about £7 10s. to £7 12s. 6d.; and the Association list rates for hoops at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

Nut and bolt makers report the improvement I noticed recently in this branch of trade, fully maintained, business for general requirements coming forward freely, but as yet no materially better prices are obtainable. Girder manufacturers are also securing a large weight of work for general constructive purposes, and have been able to advance their prices upon recent minimum quotations about 5s. per ton; steel girders of ordinary section, delivered in this district, being now quoted about £5 12s. 6d. per ton.

In the steel trade the improvement which it was anticipated would follow upon a settlement of the shipbuilding dispute is scarcely yet making itself felt to any appreciable extent. Ordinary foundry hematites can still be bought at about 55s. 6d., although general quotations are about 56s. 6d., less 2½; and steel boiler plates are obtainable without difficulty at £6 5s., delivered in this district.

In the metal market all descriptions of manufactured goods continue in active request, orders coming to hand freely from the various engineering branches of trade, whilst the continued upward movement in copper goods gives a hardening tendency to prices, which may possibly result in some official advance in list rates before very long.

Wire netting manufacturers also report not only an active demand on home accounts, but what is perhaps still more satisfactory, a revival of the Australian demand, which has been exceedingly quiet for the last couple of years, some firms having now orders from the above quarter for rabbit netting which will keep them well employed over the next three or four months.

Locomotive builders in this district, who for a long time past have been very short of work, are securing a very fair weight of orders, one firm having during last week booked a tolerably good one from Japan, and most of the establishments in this district, which are now tolerably well engaged, are, I believe, in a much better position than similar establishments in Yorkshire, and the north boilermakers are also booking new work more freely than they have been for some time past. With regard to other branches of the engineering trade, they continue well engaged, the improvement I have recently reported being well maintained.

As the official report with reference to the settlement of the dispute in the Bolton engineering trade, which I noticed last week, practically confirms the particulars I then gave, I need not refer further to this matter.

A special plant of machine tools for manufacturing dynamo brushes by an improved process has just been put down by Messrs. Johnson, Clapham, and Morris at their works in Manchester. By this new process the wire cloth is specially compressed, in such a manner as to render the dynamo brushes—which are being manufactured not only in copper, but also in brass wire—more solid, thus giving them an increased stiffness. When brought in contact with the revolving armature, the advantage gained being that they maintain a much steadier pressure upon the armature as compared with the ordinary brushes in use generally.

An interesting paper on the transmission and application of power to machine tools, &c., written by the late Mr. R. H. Tweddell, M. Inst. C.E., of London, was read before the members of the Manchester Association of Engineers at their meeting on Saturday. The paper stated that in the author's opinion there was a large field open for the application of electric motors to machine tools, not only on the score of transmission of power over long distances, but also its convenience when the question of working sections only of a shop or a single machine placed amongst many others was to be considered. It would, however, be well for works' managers to proceed cautiously in adopting electricity, or they might soon be metaphorically struggling in tunics sewed up for them by too impulsive electricians. For transmitting power over long distances, both water and electricity had their special advantages. Electricity as a motive power for moderate sized machines in frequent work certainly seemed to fulfil most of the conditions, but one disadvantage was that the machines had to wait till the speed of the motor was got up, and a similar loss of power occurred when the machine was being stopped, whereas the hydraulic machine only consumed power while work was actually being done. There were, of course, losses peculiar to the hydraulic system, and climatic conditions to be considered, and the final verdict as to the power selected could only be the result of experience and judgment in each particular case.

In many classes of work it was essential that the exact pressure exerted be known, and that the same pressure be exerted every time it was applied under similar conditions. This was especially the case in the riveting, and for this hydraulic machines were particularly applicable, the range of travel being one of their chief advantages, which was practically unobtainable in geared machines, whether driven by shafting or electric motors. Simplicity and fewness of parts should be the aim of the hydraulic engineers. Many apparently satisfactory mechanical devices had been brought out to economise the water consumed, but the only really efficient one—when suitable—was that due to the use of an overhead tank and simple non-return valve, or in some special cases the use of three rams. There was no doubt but that in the future electricity would have to be considered as one of the factors in an economical works plant, and in some cases it would supplant both shafting and hydraulic pressure, but there would always be applications left for the older systems.

A short discussion followed upon the paper, during which the president (Mr. Nasmith) remarked that where they had to do heavy work quickly, as in flanging up a boiler front, or in stamping, &c., the hydraulic system filled all requirements, as a large force could be applied very quickly and with the least possible loss. The claim now made for electrical transmission of power from a central source was simply a resuscitation of that made by Mr. Tweddell for hydraulic power twenty years ago, *i.e.*, that it was a more economical method of transmitting power over long distances than any at present existing. Mr. Jenkins observed that electricity had many conveniences that no other power could have. For instance, they could put electrical machines almost anywhere in a works. As compared with shafting, it was no doubt in some cases less, but in many cases—especially where coal was dear—it was more economical. Two drawbacks to hydraulic power were the comparatively small power that could be transmitted through a pipe of ordinary dimensions and its inapplicability to rotary machines.

The coal trade still shows an absence of improvement—many collieries working only about four, and in some cases not more than three days per week — with supplies of all descriptions of fuel plentiful, notwithstanding the restricted get. House-fire qualities are moving off but very indifferently for the time of the year, and prices are barely maintained at late rates. Although the lower descriptions of round coal meet with a fair demand for ironmaking, steam and general manufacturing purposes, supplies continue largely in excess of requirements, and prices extremely low, not averaging above 6s. per ton at the pit mouth for good ordinary steam and forge coals. Engine fuel moves off fairly well, owing to the limited production of slack at many of the collieries, and prices are steady at 3s. to 3s. 6d. for common sorts to 4s. 6d. for better qualities, and 5s. for some special descriptions, at the pit mouth.

For shipment a moderate business comes forward, but prices continue excessively low, ordinary steam coal being still sold at 7s. to 7s. 6d.. with better qualities fetching about 7s. 9d., delivered Mersey ports.

Barrow.—The hematite pig iron trade is gaining strength, and there is a distinct improvement on the week, not only in prompt but forward demand, and prices are firmer at 47s. 7½d. per ton, net cash, sellers; 1d. less buyers. Makers' iron is nominally quoted at 48s. 6d. to 50s. per ton, net, f.o.b. The trade in Bessemer for forward delivery is increasing. Makers are arranging to light several idle furnaces. At present only 35 out of 75 furnaces are in blast, compared with 29 in blast in the corresponding week of last year. Stocks of iron are steady, there being only an increase of 42 tons on the week. Stocks in hand now represent 298,020 tons, being 8845 tons more than at the beginning of the year.

There is not so much life in the iron ore trade owing to a big importation of Spanish ores, value being at 10s. per ton net at mines, and Spanish at 12s., delivered at West Coast ports. The latter is 60 per cent. quality.

Steel makers are as busy as can be with rails, plates, and merchant qualities. There is also a good demand for billets and hoops, but the mills at Barrow will be stopped for a few works longer in consequence of the recent accident. In tin-plate bars, slabs and blooms, a very quiet trade is doing.

The shipbuilding trade is very busy chiefly on Admiralty work, but new commercial orders are expected this year as well as additional Admiralty orders.

The Furness Railway Company has ordered three new passenger locomotives from Messrs. Sharp, Stewart, and Co., Glasgow. They are to have 6ft. driving wheels, 18in. cylinders, 24in. stroke, and a water carrying capacity in the tenders of 2500 gallons.

The coal trade is firmer and steady. Orders are on the increase for coal as well as for coke, and prices are firmer, but not higher.

The shipping trade is still depressed. The exports from West Coast ports during last week represented 2080 tons of pig iron, and 4951 tons of steel, compared with 2075 tons of pig iron, and 2461 tons of steel in the corresponding week of last year, an increase of five tons of pig iron and 2490 tons of steel. The aggregate total of shipments to date represents 22,591 tons of pig iron, and 34,137 tons of steel, compared with 15,418 tons of pig iron, and 21,581 tons of steel in the corresponding period of last year, an increase of 7173 tons of pig iron, and 12,556 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

IN South Yorkshire and adjoining coalfields, the pits are fairly well employed, notwithstanding the excessively mild weather and the fact that the production amply meets the present demand. A dispute at one of the local collieries is now happily settled, although there are indications of another rupture which may culminate in a strike or lockout in the near future. House coal, owing to the remarkable geniality of the month, is but indifferently ordered. Reports from all parts of the coalfield are similarly discouraging in house sorts. A slight tonnage, for the season of the year, is going to London, both in Silkstone and Barnsley thick seam, and prices are rather below those ordinarily obtained during the first month. Consumers in the Metropolis exhibit a preference for Silkstone over other household coal, and this class of fuel is at present quoted at from 8s. 6d. to 9s. 6d. for the best, with 7s. to 7s. 6d. for secondary sorts; Barnsley thick seam is sold at 7s. 9d. to 8s. 6d.; while Flockton fetches about the same price; thin seam, even of the finest qualities, can only realise 6s. to 6s. 3d. at the pits. The demand for steam coal is very limited, and only a poor tonnage is leaving the district for exportation. The bulk of the weight sent to Hull from this coalfield is mainly for the use of steamers in that port. Grimsby is taking a fair supply; business with Goole is very poor. Railway companies continue to require an average amount of locomotive fuel on contract account. Prices in the open market are from 6s. 6d. to 7s. 3d. per ton at the pits. The request, however, is not large enough to prevent the accumulation of stocks. Gas coal is reported in less demand, a fact which is also due to the open weather at present prevailing. Small coal and slack, which a month ago showed some slight advance, has again fallen back to languid request. All descriptions of slack are plentiful, and quotations are about the same. Good screened makes from 3s. 9d. to 4s. 3d. per ton; ordinary pit slack at 2s. 3d. to 2s. 6d., with some difficulty in disposing of quantities. Smudge is obtainable for 1s. per ton. Coke is reported in steady demand both from Derbyshire and North Lincolnshire. Values are better, being 8s. to 9s. 6d., with 6d. less for contracts, as compared with the price obtained three months ago.

Notwithstanding the political troubles which at present gather about this country, all the heavy industries of Sheffield are in a good condition. Foreign markets have opened their business very well during the New Year. This remark applies more particularly to the United States and the South American markets. The Australian business is again beginning to look up. Bar iron and Bessemer steel are in excellent request. Inquiries for the former are so numerous that it is not unlikely that prices will advance shortly. Quotations are as follows:—Hematites are obtainable at 57s. 6d. for West Coast varieties delivered in Sheffield; East Coast irons 2s. 6d. a ton less. Lincolnshire forge iron, 39s.; Bessemer billets, special carbons, used in the Sheffield trades, £5 12s. 6d. and upwards; bar iron at from £5 10s. at makers' works; foundry iron fetches 41s. to 42s. The end of the dispute in the shipbuilding trade is likely to have a most beneficial effect on the Sheffield industries. During the strike our local manufacturers have been much hampered by Scotch firms, who, deprived of their ordinary source of employment, were compelled to look to other markets to keep their works going. They therefore entered into competition with Sheffield and other makers, and literally took the work out of their fingers by accepting it at almost any price they could get. Directly the shipbuilding yards get fairly to work some considerable relief will thus be afforded by the dropping off of these competitors, and the resumption of employment in their own districts. The makers of railway tires, axles, buffers, springs, &c., are now fully employed. A good demand has sprung up with the New Year for cross cut and circular saws for the great wood-growing markets. Russia is one of the principal customers for this class of goods. Continental as well as home makers are placing a considerable number of orders for special steel. The engineering trades have received a slight spurt, although this has been rather damped by the troubles in the Transvaal, which have had the effect of rather decreasing the export of mining tools. It is expected, however, that this business will soon revive and be as active as before Dr. Jameson's raid.
